[PE2] interface vlan-interface 12
[PE2-Vlan-interface12] ip binding vpn-instance vpn1
[PE2-Vlan-interface12] ip address 20.0.0.1 24
[PE2-Vlan-interface12] quit
```

Create a routing policy and specify a label index value.

```
[PE2] route-policy policy1 permit node 1
[PE2-route-policy-policy1-1] apply label-index 50
[PE2-route-policy-policy1-1] quit
```

Start BGP on PE 2. Enable the capability to exchange labeled routes with IBGP peer 4.4.4.9.

```
[PE2] bgp 600
[PE2-bgp-default] peer 4.4.4.9 as-number 600
[PE2-bgp-default] peer 4.4.4.9 connect-interface loopback 1
[PE2-bgp-default] address-family ipv4 unicast
[PE2-bgp-default-ipv4] peer 4.4.4.9 enable
[PE2-bgp-default-ipv4] peer 4.4.4.9 label-route-capability
```

Enable SR-MPLS.

```
[PE2-bgp-default-ipv4] segment-routing mpls
```

Redistribute the route of loopback interface 1 to BGP and apply the routing policy.

```
[PE2-bgp-default-ipv4] network 5.5.5.9 32 route-policy policy1
[PE2-bgp-default-ipv4] quit
```

Configure the maximum number of hops from PE 2 to EBGP peer 2.2.2.9 as 10.

```
[PE2-bgp-default] peer 2.2.2.9 as-number 100
[PE2-bgp-default] peer 2.2.2.9 connect-interface loopback 1
[PE2-bgp-default] peer 2.2.2.9 ebgp-max-hop 10
```

Configure peer 2.2.2.9 as a VPNv4 peer.

```
[PE2-bgp-default] address-family vpnv4
[PE2-bgp-default-vpnv4] peer 2.2.2.9 enable
[PE2-bgp-default-vpnv4] quit
```

Configure CE 2 as an EBGP peer of PE 2 and install the learned BGP routes in the routing table of the VPN instance.

```
[PE2-bgp-default] ip vpn-instance vpn1
[PE2-bgp-default-vpn1] peer 20.0.0.2 as-number 65001
[PE2-bgp-default-vpn1] address-family ipv4 unicast
[PE2-bgp-default-ipv4-vpn1] peer 20.0.0.2 enable
```

7. Configure CE 2:

Assign an IP address to interface VLAN-interface 12.

```
<CE2> system-view
```

```
[CE2] interface vlan-interface 12
[CE2-Vlan-interface12] ip address 20.0.0.2 24
[CE2-Vlan-interface12] quit
```

Establish an EBGP peer relationship with PE 2, and redistribute VPN routes.

```
[CE2] bgp 65002
[CE2-bgp-default] peer 20.0.0.1 as-number 600
[CE2-bgp-default] address-family ipv4 unicast
[CE2-bgp-default-ipv4] peer 20.0.0.1 enable
[CE2-bgp-default-ipv4] import-route direct
[CE2-bgp-default-ipv4] quit
[CE2-bgp-default] quit
```

Verifying the configuration

Execute the **`display ip routing-table`** command on CE 1 and CE 2 to verify that they have a route to each other. (Details not shown.)

Verify that CE 1 and CE 2 can ping each other. (Details not shown.)

Display MPLS LSP information on PE1.

```
[PE1]display mpls lsp
```

FEC	Proto	In/Out Label	Out Inter/NHLFE/LSINDEX
2.2.2.9/32	BGP	3/-	-
5.5.5.9/32	BGP	-/16040	NHLFE17
5.5.5.9	BGP	-/-	Vlan11
1.1.1.1	Local	-/-	Vlan11
2.2.2.9/32	ISIS	16020/-	-
3.3.3.9/32	ISIS	16030/3	Vlan11
3.3.3.9/32	ISIS	-/3	Vlan11

Example: Configuring SR-MPLS to LDP (IS-IS)

Network configuration

As shown in Figure 18, complete the following tasks so Switch A and Switch C can communicate with each other:

- Configure Switch A, Switch B, and Switch C to run IS-IS.
- Configure Switch A and Switch B to run SR-MPLS and establish an SRLSP between Switch A and Switch B.
- Configure Switch B and Switch C to run LDP to establish a dynamic LSP between Switch B and Switch C.
- Configure Switch B as the SRMS, map the prefix address of the LDP network to an SID, and advertise the mapping to Switch A.

Figure 18 Network diagram

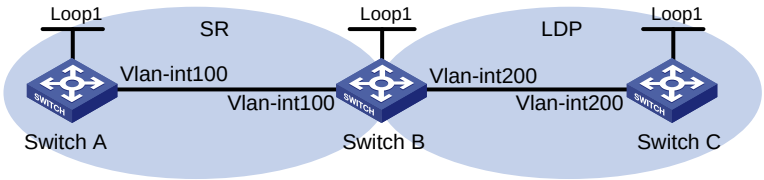

Table 2 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Switch A	Loop1	1.1.1.1/32	Switch B	Loop1	2.2.2.2/32
	Vlan-Int100	10.0.0.1/24		Vlan-Int100	10.0.0.2/24
Switch C	Loop1	3.3.3.3/32		Vlan-Int200	11.0.0.1/24
	Vlan-Int200	11.0.0.2/24			

Procedure

1. Configure IP addresses and masks for interfaces. (Details not shown.)
2. Configure IS-IS on the switches to achieve network level connectivity and set the IS-IS cost style to wide:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] network-entity 00.0000.0000.0001.00
[SwitchA-isis-1] cost-style wide
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis enable 1
[SwitchA-Vlan-interface100] quit
[SwitchA] interface loopback 1
[SwitchA-LoopBack1] isis enable 1
[SwitchA-LoopBack1] quit
```

   # Configure an IS-IS prefix SID.

```
[SwitchA] interface loopback 1
[SwitchA-LoopBack1] isis prefix-sid index 10
[SwitchA-LoopBack1] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] network-entity 00.0000.0000.0002.00
[SwitchB-isis-1] cost-style wide
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] isis enable 1
[SwitchB-Vlan-interface100] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis enable 1
[SwitchB-Vlan-interface200] quit
[SwitchB] interface loopback 1
[SwitchB-LoopBack1] isis enable 1
[SwitchB-LoopBack1] quit
```

   # Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis 1
```

```
[SwitchC-isis-1] network-entity 00.0000.0000.0003.00
[SwitchC-isis-1] cost-style wide
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] isis enable 1
[SwitchC-Vlan-interface200] quit
[SwitchC] interface loopback 1
[SwitchC-LoopBack1] isis enable 1
[SwitchC-LoopBack1] quit
```

3. Configure LSR IDs on the switches:

Configure Switch A.

```
[SwitchA] mpls lsr-id 1.1.1.1
```

Configure Switch B.

```
[SwitchB] mpls lsr-id 2.2.2.2
```

Configure Switch C.

```
[SwitchC] mpls lsr-id 3.3.3.3
```

4. Configure LDP on Switch B and Switch C:

Configure Switch B.

```
[SwitchB] mpls ldp
[SwitchB-ldp] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] mpls enable
[SwitchB-Vlan-interface200] mpls ldp enable
[SwitchB-Vlan-interface200] quit
```

Configure Switch C.

```
[SwitchC] mpls ldp
[SwitchC-ldp] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] mpls enable
[SwitchC-Vlan-interface200] mpls ldp enable
[SwitchC-Vlan-interface200] quit
```

5. Enable SR-MPLS on Switch A and Switch B:

Configure Switch A.

```
[SwitchA] isis 1
[SwitchA-isis-1] address-family ipv4
[SwitchA-isis-1-ipv4] segment-routing mpls
[SwitchA-isis-1-ipv4] quit
[SwitchA-isis-1] quit
```

Configure Switch B.

```
[SwitchB] isis 1
[SwitchB-isis-1] address-family ipv4
[SwitchB-isis-1-ipv4] segment-routing mpls
[SwitchB-isis-1-ipv4] quit
[SwitchB-isis-1] quit
```

6. Configure the SRMS:

On Switch B, configure the IGP to advertise locally configured prefix-SID mappings.

```
[SwitchB] isis 1
```

```
[SwitchB-isis-1] address-family ipv4
[SwitchB-isis-1-ipv4] segment-routing mapping-server advertise-local
[SwitchB-isis-1-ipv4] quit
[SwitchB-isis-1] quit
```

On Switch B, configure a prefix-SID mapping.

```
[SwitchB] segment-routing
[SwitchB-segment-routing] mapping-server prefix-sid-map 3.3.3.3 32 100
[SwitchB-segment-routing] quit
```

Verifying the configuration

Display IS-IS SRLSP information on Switch A.

```
[SwitchA] display mpls lsp protocol isis
FEC                         Proto       In/Out Label    Out Inter/NHLFE/LSINDEX
3.3.3.3/32                  ISIS        16100/16100     Vlan100
3.3.3.3/32                  ISIS        -/16100         Vlan100
```

The output shows that the outgoing label of the IS-IS SRLSP entry for Switch C is using the SID assigned to Switch C.

Example: Configuring SR-MPLS over LDP

Network configuration

As shown in Figure 19, complete the following tasks so the two SR networks can communicate across the LDP network:

- Configure Switch A, Switch B, Switch C, Switch D, and Switch E to run IS-IS.
- Configure Switch B, Switch C, and Switch D to run LDP.
- Configure Switch A, Switch B, Switch D, and Switch E to run SR-MPLS.

Figure 19 Network diagram

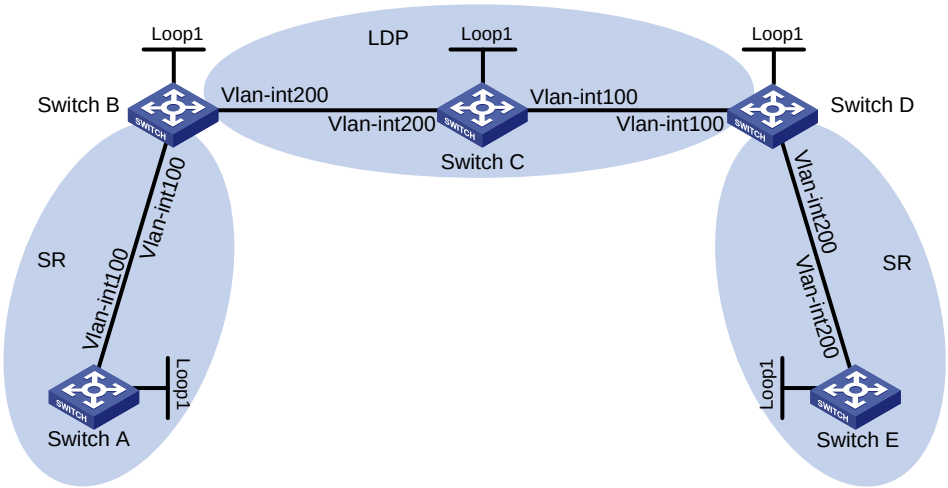

Table 3 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Switch A	Loop1	1.1.1.1/32	Switch B	Loop1	2.2.2.2/32
	Vlan-Int100	10.0.0.1/24		Vlan-Int100	10.0.0.2/24

Switch C	Loop1	3.3.3.3/32		Vlan-Int200	11.0.0.1/24
	Vlan-Int100	12.0.0.1/24	Switch D	Loop1	4.4.4.4/32
	Vlan-Int200	11.0.0.2/24		Vlan-Int100	12.0.0.2/24
Switch E	Loop1	5.5.5.5/32		Vlan-Int200	13.0.0.1/24
	Vlan-Int200	13.0.0.2/24			

Procedure

1. Configure IP addresses and masks for interfaces. (Details not shown.)
2. Configure IS-IS on the switches to achieve network level connectivity and set the IS-IS cost style to wide:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] network-entity 00.0000.0000.0001.00
[SwitchA-isis-1] cost-style wide
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis enable 1
[SwitchA-Vlan-interface100] quit
[SwitchA] interface loopback 1
[SwitchA-LoopBack1] isis enable 1
[SwitchA-LoopBack1] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] network-entity 00.0000.0000.0002.00
[SwitchB-isis-1] cost-style wide
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] isis enable 1
[SwitchB-Vlan-interface100] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis enable 1
[SwitchB-Vlan-interface200] quit
[SwitchB] interface loopback 1
[SwitchB-LoopBack1] isis enable 1
[SwitchB-LoopBack1] quit
```

   # Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis 1
[SwitchC-isis-1] network-entity 00.0000.0000.0003.00
[SwitchC-isis-1] cost-style wide
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] isis enable 1
[SwitchC-Vlan-interface100] quit
```

```
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] isis enable 1
[SwitchC-Vlan-interface200] quit
[SwitchC] interface loopback 1
[SwitchC-LoopBack1] isis enable 1
[SwitchC-LoopBack1] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] isis 1
[SwitchD-isis-1] network-entity 00.0000.0000.0004.00
[SwitchD-isis-1] cost-style wide
[SwitchD-isis-1] quit
[SwitchD] interface vlan-interface 100
[SwitchD-Vlan-interface100] isis enable 1
[SwitchD-Vlan-interface100] quit
[SwitchD] interface vlan-interface 200
[SwitchD-Vlan-interface200] isis enable 1
[SwitchD-Vlan-interface200] quit
[SwitchD] interface loopback 1
[SwitchD-LoopBack1] isis enable 1
[SwitchD-LoopBack1] quit
```

Configure Switch E.

```
<SwitchE> system-view
[SwitchE] isis 1
[SwitchE-isis-1] network-entity 00.0000.0000.0005.00
[SwitchE-isis-1] cost-style wide
[SwitchE-isis-1] quit
[SwitchE] interface vlan-interface 200
[SwitchE-Vlan-interface200] isis enable 1
[SwitchE-Vlan-interface200] quit
[SwitchE] interface loopback 1
[SwitchE-LoopBack1] isis enable 1
[SwitchE-LoopBack1] quit
```

3. Configure LSR IDs on the switches:

Configure Switch A.

```
[SwitchA] mpls lsr-id 1.1.1.1
```

Configure Switch B.

```
[SwitchB] mpls lsr-id 2.2.2.2
```

Configure Switch C.

```
[SwitchC] mpls lsr-id 3.3.3.3
```

Configure Switch D.

```
[SwitchD] mpls lsr-id 4.4.4.4
```

Configure Switch E.

```
[SwitchE] mpls lsr-id 5.5.5.5
```

4. Configure LDP on Switch B, Switch C, and Switch D:

Configure Switch B.

```
[SwitchB] mpls ldp
```

```
[SwitchB-ldp] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] mpls enable
[SwitchB-Vlan-interface200] mpls ldp enable
[SwitchB-Vlan-interface200] quit
```

Configure Switch C.

```
[SwitchC] mpls ldp
[SwitchC-ldp] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] mpls enable
[SwitchC-Vlan-interface100] mpls ldp enable
[SwitchC-Vlan-interface100] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] mpls enable
[SwitchC-Vlan-interface200] mpls ldp enable
[SwitchC-Vlan-interface200] quit
```

Configure Switch D.

```
[SwitchD] mpls ldp
[SwitchD-ldp] quit
[SwitchD] interface vlan-interface 100
[SwitchD-Vlan-interface1001] mpls enable
[SwitchD-Vlan-interface100] mpls ldp enable
[SwitchD-Vlan-interface100] quit
```

5. Enable SR-MPLS on Switch A, Switch B, Switch D, and Switch E:

Configure Switch A.

```
[SwitchA] isis 1
[SwitchA-isis-1] address-family ipv4
[SwitchA-isis-1-ipv4] segment-routing mpls
[SwitchA-isis-1-ipv4] quit
[SwitchA-isis-1] quit
```

Configure Switch B.

```
[SwitchB] isis 1
[SwitchB-isis-1] address-family ipv4
[SwitchB-isis-1-ipv4] segment-routing mpls
[SwitchB-isis-1-ipv4] quit
[SwitchB-isis-1] quit
```

Configure Switch D.

```
[SwitchD] isis 1
[SwitchD-isis-1] address-family ipv4
[SwitchD-isis-1-ipv4] segment-routing mpls
[SwitchD-isis-1-ipv4] quit
[SwitchD-isis-1] quit
```

Configure Switch E.

```
[SwitchE] isis 1
[SwitchE-isis-1] address-family ipv4
[SwitchE-isis-1-ipv4] segment-routing mpls
[SwitchE-isis-1-ipv4] quit
[SwitchE-isis-1] quit
```

6. Configure IS-IS prefix SIDs for Switch A, Switch B, Switch D, and Switch E:

   # Configure Switch A.

```
[SwitchA] interface loopback 1
[SwitchA-LoopBack1] isis prefix-sid index 10
[SwitchA-LoopBack1] quit
```

   # Configure Switch B.

```
[SwitchB] interface loopback 1
[SwitchB-LoopBack1] isis prefix-sid index 20
[SwitchB-LoopBack1] quit
```

   # Configure Switch D.

```
[SwitchD] interface loopback 1
[SwitchD-LoopBack1] isis prefix-sid index 40
[SwitchD-LoopBack1] quit
```

   # Configure Switch E.

```
[SwitchE] interface loopback 1
[SwitchE-LoopBack1] isis prefix-sid index 50
[SwitchE-LoopBack1] quit
```

Verifying the configuration

Display LDP LSP information on Switch B.

```
[SwitchB] display mpls ldp lsp
Status Flags: * - stale, L - liberal, B - backup, N/A - unavailable
FECs: 5           Ingress: 3           Transit: 3           Egress: 2

FEC                In/Out Label        Nexthop         OutInterface/LSINDEX
1.1.1.1/32         2173/-
                   -/2173(L)
2.2.2.2/32         3/-
                   -/2175(L)
3.3.3.3/32         -/3                 11.0.0.2        Vlan200
                   2175/3              11.0.0.2        Vlan200
4.4.4.4/32         -/2174              11.0.0.2        Vlan200
                   2174/2174           11.0.0.2        Vlan200
5.5.5.5/32         -/2172              11.0.0.2        Vlan200
                   2172/2172           11.0.0.2        Vlan200
```

Display IS-IS SRLSP information on Switch B.

```
[SwitchB] display mpls lsp protocol isis
FEC                          Proto       In/Out Label    Out Inter/NHLFE/LSINDEX
1.1.1.1/32                   ISIS        16010/3         Vlan100
1.1.1.1/32                   ISIS        -/3             Vlan100
2.2.2.2/32                   ISIS        16020/-         -
4.4.4.4/32                   ISIS        16040/2174      Vlan200
4.4.4.4/32                   ISIS        -/2174          Vlan200
5.5.5.5/32                   ISIS        16050/2172      Vlan200
5.5.5.5/32                   ISIS        -/2172          Vlan200
```

The output shows that the IS-IS SRLSP entries for Switch D and Switch E are using LDP labels.

Preface

This configuration guide describes fundamentals and configuration procedures for ACL, QoS, time range, and data buffer.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators working with the S5570S-EI and S5500V3-SI switch series.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

Configuring ACLs

Only the S5200-HI-G switch series supports user-defined ACLs.

About ACLs

An access control list (ACL) is a set of rules for identifying traffic based on criteria such as source IP address, destination IP address, and port number. The rules are also called permit or deny statements.

ACLs are primarily used for packet filtering. You can also use ACLs in QoS, security, routing, and other modules for identifying traffic. The packet drop or forwarding decisions depend on the modules that use ACLs.

Numbering and naming ACLs

When creating an ACL, you must assign it a number or name for identification. You can specify an existing ACL by its number or name. Each ACL type has a unique range of ACL numbers.

For basic or advanced ACLs with the same number, you must use the **`ipv6`** keyword to distinguish them. For ACLs with the same name, you must use the **`ipv6`**, **`mac`**, and **`user-defined`** keywords to distinguish them.

ACL types

Type	ACL number	IP version	Match criteria
Basic ACLs	2000 to 2999	IPv4	Source IPv4 address.
		IPv6	Source IPv6 address.
Advanced ACLs	3000 to 3999	IPv4	Source IPv4 address, destination IPv4 address, packet priority, protocol number, and other Layer 3 and Layer 4 header fields.
		IPv6	Source IPv6 address, destination IPv6 address, packet priority, protocol number, and other Layer 3 and Layer 4 header fields.
Layer 2 ACLs	4000 to 4999	IPv4 and IPv6	Layer 2 header fields, such as source and destination MAC addresses, 802.1p priority, and link layer protocol type.
User-defined ACLs	5000 to 5999	IPv4 and IPv6	User specified matching patterns in protocol headers.

Match order

The rules in an ACL are sorted in a specific order. When a packet matches a rule, the device stops the match process and performs the action defined in the rule. If an ACL contains overlapping or conflicting rules, the matching result and action to take depend on the rule order.

The following ACL match orders are available:

- **config**—Sorts ACL rules in ascending order of rule ID. A rule with a lower ID is matched before a rule with a higher ID. If you use this method, check the rules and their order carefully.

NOTE:

The match order of user-defined ACLs can only be **config**.

- **auto**—Sorts ACL rules in depth-first order. Depth-first ordering makes sure any subset of a rule is always matched before the rule. The following table lists the sequence of tie breakers that depth-first ordering uses to sort rules for each type of ACL.

Table 1 Sort ACL rules in depth-first order

ACL type	Sequence of tie breakers
IPv4 basic ACL	**1.** VPN instance. **1.** More 0s in the source IPv4 address wildcard (more 0s means a narrower IPv4 address range). **2.** Rule configured earlier.
IPv4 advanced ACL	**1.** VPN instance. **2.** Specific protocol number. **3.** More 0s in the source IPv4 address wildcard mask. **4.** More 0s in the destination IPv4 address wildcard. **5.** Narrower TCP/UDP service port number range. **6.** Rule configured earlier.
IPv6 basic ACL	**1.** VPN instance. **2.** Longer prefix for the source IPv6 address (a longer prefix means a narrower IPv6 address range). **3.** Rule configured earlier.
IPv6 advanced ACL	**1.** VPN instance. **2.** Specific protocol number. **3.** Longer prefix for the source IPv6 address. **4.** Longer prefix for the destination IPv6 address. **5.** Narrower TCP/UDP service port number range. **6.** Rule configured earlier.
Layer 2 ACL	**1.** More 1s in the source MAC address mask (more 1s means a smaller MAC address). **2.** More 1s in the destination MAC address mask. **3.** Rule configured earlier.

A wildcard mask, also called an inverse mask, is a 32-bit binary number represented in dotted decimal notation. In contrast to a network mask, the 0 bits in a wildcard mask represent "do care" bits, and the 1 bits represent "don't care" bits. If the "do care" bits in an IP address are identical to the "do care" bits in an IP address criterion, the IP address matches the criterion. All "don't care" bits are ignored. The 0s and 1s in a wildcard mask can be noncontiguous. For example, 0.255.0.255 is a valid wildcard mask.

Comments and remarks for rules

An ACL can have multiple rules. To identify rules, you can add a comment for each rule one by one, or add the same remark for multiple rules.

- For rules requiring different identification, you can add a comment for a particular rule or add a different comment for each rule.
- For a range of rules requiring the same identification, you can insert a remark before the start rule and a remark after the end rule. This configuration mode eliminates the need for configuring a comment for each rule one by one and improves configuration efficiency.

Rule numbering

ACL rules can be manually numbered or automatically numbered. This section describes how automatic ACL rule numbering works.

Rule numbering step

If you do not assign an ID to the rule you are creating, the system automatically assigns it a rule ID. The rule numbering step sets the increment by which the system automatically numbers rules. For example, the default ACL rule numbering step is 5. If you do not assign IDs to rules you are creating, they are automatically numbered 0, 5, 10, 15, and so on. The wider the numbering step, the more rules you can insert between two rules.

By introducing a gap between rules rather than contiguously numbering rules, you have the flexibility of inserting rules in an ACL. This feature is important for a config-order ACL, where ACL rules are matched in ascending order of rule ID.

The rule numbering step sets the increment by which the system numbers rules automatically. If you do not specify a rule ID when creating an ACL rule, the system automatically assigns it a rule ID. This rule ID is the nearest higher multiple of the numbering step to the current highest rule ID, starting from the start rule ID. For example, if the rule numbering step is 5 and the current highest rule ID is 12, the rule is numbered 15.

The wider the numbering step, the more rules you can insert between two rules. Whenever the step or start rule ID changes, the rules are renumbered, starting from the start rule ID. For example, if there are five rules numbered 0, 5, 9, 10, and 15, changing the step from 5 to 2 causes the rules to be renumbered 0, 2, 4, 6, and 8.

Automatic rule numbering and renumbering

The ID automatically assigned to an ACL rule takes the nearest higher multiple of the numbering step to the current highest rule ID, starting with 0.

For example, if the step is 5, and there are five rules numbered 0, 5, 9, 10, and 12, the newly defined rule is numbered 15. If the ACL does not contain a rule, the first rule is numbered 0.

Whenever the step changes, the rules are renumbered, starting from 0. For example, changing the step from 5 to 2 renumbers rules 5, 10, 13, and 15 as rules 0, 2, 4, and 6.

For an ACL of the match order **auto**, rules are sorted in depth-first order, and are renumbered based on the match order. For example, rules are in the match order of 0, 10, and 5. Changing the numbering step to 2 renumbers rules 0, 10, and 5 (not 0, 5, and 10) as rules 0, 2, 4.

Fragment filtering with ACLs

Traditional packet filtering matches only first fragments of packets, and allows all subsequent non-first fragments to pass through. Attackers can fabricate non-first fragments to attack networks.

To avoid risks, the ACL feature is designed as follows:

- Filters all fragments by default, including non-first fragments.
- Allows for matching criteria modification for efficiency. For example, you can configure the ACL to filter only non-first fragments.

Restrictions and guidelines: ACL configuration

- If you create a numbered ACL, you can enter the view of the ACL by using either of the following commands:
  - **acl** [**ipv6**] **number** *acl-number*.
  - **acl** { [**ipv6**] { **advanced** | **basic** } | **mac** | **user-defined** } *acl-number*.

- If you create a ACL by using the **acl** [**ipv6**] **number** *acl-number* **name** *acl-name* command, you can enter the view of the ACL by using either of the following commands:
  - **acl** [**ipv6**] **name** *acl-name* (for only basic ACLs and advanced ACLs).
  - **acl** [**ipv6**] **number** *acl-number* [**name** *acl-name*].
  - **acl** { [**ipv6**] { **advanced** | **basic** } | **mac** | **user-defined** } **name** *acl-name*.
- If you create a named ACL by using the **acl** { [**ipv6**] { **advanced** | **basic** } | **mac** | **user-defined** } **name** *acl-name* command, you can enter the view of the ACL by using either of the following commands:
  - **acl** [**ipv6**] **name** *acl-name* (for only basic ACLs and advanced ACLs).
  - **acl** { [**ipv6**] { **advanced** | **basic** } | **mac** | **user-defined** } **name** *acl-name*.

ACL tasks at a glance

To configure an ACL, perform the following tasks:

- Configure ACLs according to the characteristics of the packets to be matched
  - Configuring a basic ACL
  - Configuring an advanced ACL
  - Configuring a Layer 2 ACL
  - Configuring a user-defined ACL
- (Optional.) Copying an ACL
- (Optional.) Configuring the QoS and ACL resource hardware mode
- (Optional.) Configuring packet filtering with ACLs
- (Optional.) Configuring an EM template and its match criteria

Configuring a basic ACL

About basic ACLs

Basic ACLs match packets based only on source IP addresses.

Basic ACLs can be used in the following scenarios:

- To improve security when the device acts as an FTP or TFTP server, you can use basic ACLs to allow only matching clients to access the server. For more information, see FTP and TFTP configuration in *Fundamentals Configuration Guide*.
- In a multicast scenario, you can use basic ACLs in a multicast source policy to receive or forward only matching multicast packets. For more information about multicast source policy, see PIM configuration and IPv6 PIM configuration in *IP Multicast Configuration Guide*.
- To filter routes in a routing policy, you can use basic ACLs to receive or send matching routes. For more information about routing policy, see *Layer 3—IP Routing Configuration Guide*.
- To take different QoS actions on different traffic types, you can use basic ACLs to classify traffic. For more information about traffic classes, see "Configuring QoS."

Configuring an IPv4 basic ACL

1. Enter system view.
   system-view

2. Create an IPv4 basic ACL and enter its view. Choose one option as needed:
   - Create an IPv4 basic ACL by specifying an ACL number.

     acl number *acl-number* [**name** *acl-name*] [**match-order** { **auto** | **config** }]
   - Create an IPv4 basic ACL by specifying the **basic** keyword.

     acl basic { *acl-number* | **name** *acl-name* } [**match-order** { **auto** | **config** }]
3. (Optional.) Configure a description for the IPv4 basic ACL.

   description *text*

   By default, an IPv4 basic ACL does not have a description.
4. (Optional.) Set the rule numbering step.

   step *step-value* [**start** *start-value*]

   By default, the rule numbering step is 5 and the start rule ID is 0.
5. Create or edit a rule.

   rule [*rule-id*] { **deny** | **permit** } [**counting** | **fragment** | [**flow-logging** | **logging**] | **source** { **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

   The **flow-logging** or **logging** keyword takes effect only when the module (for example, packet filtering) that uses the ACL supports logging.
6. (Optional.) Add or edit a rule comment.

   rule *rule-id* **comment** *text*

   By default, no rule comment is configured.
7. (Optional.) Add a rule remark.

   rule [*rule-id*] **remark** *text*

   By default, no rule remark is configured.

Configuring an IPv6 basic ACL

1. Enter system view.

   system-view
2. Create an IPv6 basic ACL view and enter its view. Choose one option as needed:
   - Create an IPv6 basic ACL by specifying an ACL number.

     acl ipv6 number *acl-number* [**name** *acl-name*] [**match-order** { **auto** | **config** }]
   - Create an IPv6 basic ACL by specifying the **basic** keyword.

     acl ipv6 basic { *acl-number* | **name** *acl-name* } [**match-order** { **auto** | **config** }]
3. (Optional.) Configure a description for the IPv6 basic ACL.

   description *text*

   By default, an IPv6 basic ACL does not have a description.
4. (Optional.) Set the rule numbering step.

   step *step-value* [**start** *start-value*]

   By default, the rule numbering step is 5 and the start rule ID is 0.
5. Create or edit a rule.

rule [*rule-id*] { **deny** | **permit** } [**counting** | **fragment** | [**flow-logging** | **logging**] | **routing** [**type** *routing-type*] | **source** { **object-group** *address-group-name* | *source-address source-prefix* | *source-address*/*source-prefix* | **any** } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

The **flow-logging** or **logging** keyword takes effect only when the module (for example, packet filtering) that uses the ACL supports logging.

6. (Optional.) Add or edit a rule comment.

   rule *rule-id* **comment** *text*

   By default, no rule comment is configured.

7. (Optional.) Add a rule remark.

   rule [*rule-id*] **remark** *text*

   By default, no rule remark is configured.

Configuring an advanced ACL

About advanced ACLs

Advanced ACLs can be used in the following scenarios:

- When the device acts as an FTP or TFTP server, you can use advanced ACLs to allow only matching clients to access the server. For more information, see FTP and TFTP configuration in *Fundamentals Configuration Guide*.
- In a multicast scenario, you can use advanced ACLs in a multicast source policy to receive or forward only matching multicast packets. For more information about multicast source policy, see PIM configuration and IPv6 PIM configuration in *IP Multicast Configuration Guide*.
- To filter routes in a routing policy, you can use advanced ACLs to receive or send matching routes. For more information about routing policy, see *Layer 3—IP Routing Configuration Guide*.
- To take different QoS actions on different traffic types, you can use advanced ACLs to classify traffic. For more information about traffic classification see "Configuring QoS."

Advanced ACLs match packets based on the following criteria:

- Source IP addresses.
- Destination IP addresses.
- Packet priorities.
- Local QoS IDs.
- Protocol types.
- Other protocol header information, such as TCP/UDP source and destination port numbers, TCP flags, ICMP message types, and ICMP message codes.
- Encapsulation types.
- Inner source IPv4 addresses.
- Inner destination IPv4 addresses.
- Inner protocol types.
- Other inner protocol header information, such as inner TCP/UDP source and destination port numbers.

Compared to basic ACLs, advanced ACLs allow more flexible and accurate filtering.

Configuring an IPv4 advanced ACL

1. Enter system view.

   system-view

2. Create an IPv4 advanced ACL and enter its view. Choose one option as needed:

   - Create a numbered IPv4 advanced ACL by specifying an ACL number.

     acl number *acl-number* [**name** *acl-name*] [**match-order** { **auto** | **config** }]

   - Create an IPv4 advanced ACL by specifying the **advanced** keyword.

     acl advanced { *acl-number* | **name** *acl-name* } [**match-order** { **auto** | **config** }]

3. (Optional.) Configure a description for the IPv4 advanced ACL.

   description *text*

   By default, an IPv4 advanced ACL does not have a description.

4. (Optional.) Set the rule numbering step.

   step *step-value* [**start** *start-value*]

   By default, the rule numbering step is 5 and the start rule ID is 0.

5. Create or edit a rule. Choose the options to configure as needed:

   - Create or edit a rule for matching non-encapsulated packets.

     rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { { **precedence** *precedence* | **tos** *tos* } * | { **precedence** *precedence* | **ecn** *ecn* } * | { **dscp** *dscp* | **ecn** *ecn* } * } | [**any-fragment** | **first-fragment** | **fragment** | **non-fragment** | **non-or-first-fragment**] | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **packet-length** *operator length-value1* [*length-value2*] | **qos-local-id** *local-id-value* | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **user-group** *group-name* | **vpn-instance** *vpn-instance-name*] *

   - Create or edit a rule for matching encapsulated packets.

     rule [*rule-id*] { **deny** | **permit** } { **gre-encapsulation** | **ipinip-encapsulation** | **vxlan** | **geneve** } [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | **inner-source-port** *operator port1* [*port2*] | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence**

inner-precedence } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | [**flow-logging** | **logging**] | **packet-length** *operator length-value1* [*length-value2*] | **time-range** *time-range-name*] *

Parameter	Description
gre-encapsulation	Matches GRE packets. The **source-port** *operator port1* [*port2*] and **vxlan-id** *vxlan-id* options cannot be configured if you specify the **gre-encapsulation** keyword.
ipinip-encapsulation	Matches IP-in-IP encapsulation packets. The **source-port** *operator port1* [*port2*] and **vxlan-id** *vxlan-id* options cannot be configured if you specify the **ipinip-encapsulation** keyword.
vxlan	Matches VXLAN packets by both outer and inner packet information.
geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

6. Create or edit a rule.

   rule [*rule-id*] { **deny** | **permit** } *protocol* [**counting** | **destination** { *dest-address dest-wildcard* | **any** } | **destination-port** *operator port1* [*port2*] | { **dscp** *dscp* | **precedence** *precedence* } | [**first-fragment** | **fragment** | **non-fragment** | **non-or-first-fragment**] | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | **logging** | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **time-range** *time-range-name*] *

7. Create or edit a rule.
   - Create or edit a rule for matching non-encapsulated packets.

     rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** *operator port1* [*port2*] | { { **precedence** *precedence* | **tos** *tos* } * | { **precedence** *precedence* | **ecn** *ecn* } * | { **dscp** *dscp* | **ecn** *ecn* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **qos-local-id** *local-id-value* | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

     In a VXLAN network, only the inner header information of VXLAN packets can be matched on edge devices, and only the outer header information of VXLAN packets can be matched on core devices.
   - Create or edit a rule for matching encapsulated packets.

     rule [*rule-id*] { **deny** | **permit** } **vxlan** [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination**

{ *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | **inner-source-port** *operator port1* [*port2*] | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner header information.

8. Create or edit a rule. Choose the options to configure as needed:

- Create or edit a rule for matching non-encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { { **precedence** *precedence* | **tos** *tos* } * | { **precedence** *precedence* | **ecn** *ecn* } * | { **dscp** *dscp* | **ecn** *ecn* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **qos-local-id** *local-id-value* | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

- Create or edit a rule for matching encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan** | **geneve** } [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | **inner-source-port** *operator port1* [*port2*] | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner packet information.

geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

9. Create or edit a rule.

rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { *dest-address dest-wildcard* | **any** } | **destination-port** *operator port1* [*port2*] | { { **precedence** *precedence* | **tos** *tos* } * | **precedence** *precedence* | **dscp** *dscp* } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | **logging** | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **time-range** *time-range-name*] *

10. Create or edit a rule.

rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { *dest-address dest-wildcard* | **any** } | **destination-port** *operator port1* [*port2*] | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * } | [**any-fragment** | **first-fragment** | **fragment** | **non-fragment** | **non-or-first-fragment**] | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **qos-local-id** *local-id-value* | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name* | **vpn-instance** *vpn-instance-name*] *

The S5200-EI-G switch series does not support the following keywords:

- **any-fragment**
- **first-fragment**
- **non-fragment**
- **non-or-first-fragment**

11. Create or edit a rule.

rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { *dest-address dest-wildcard* | **any** } | **destination-port** *operator port1* [*port2*] | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | **logging** | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

12. Create or edit a rule.

rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **source** { **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

13. Create or edit a rule.
    - Create or edit a rule for matching non-encapsulated packets.

      rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **qos-local-id** *local-id-value* | **source** { **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *
    - Create or edit a rule for matching encapsulated packets.

      rule [*rule-id*] { **deny** | **permit** } { **vxlan** | **geneve** } [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | **inner-source-port** *operator port1* [*port2*] | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner packet information.
geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

14. Create or edit a rule.
    - Create or edit a rule for matching non-encapsulated packets.

      rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { *dest-address dest-wildcard* | **any** } | **destination-port** *operator port1* [*port2*] | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *
    - Create or edit a rule for matching encapsulated packets.

rule [*rule-id*] { **deny** | **permit** } **vxlan** [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | **inner-source-port** *operator port1* [*port2*] | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner header information.

15. Create or edit a rule.

rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

Only the S5560X-HI and S6520X-HI switch series support the **microsegment** parameter.

16. Create or edit a rule.

- Create or edit a rule for matching non-encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** *operator port1* [*port2*] | { { **precedence** *precedence* | **tos** *tos* } * | { **precedence** *precedence* | **ecn** *ecn* } * | { **dscp** *dscp* | **ecn** *ecn* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

- Create or edit a rule for matching encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } **vxlan** [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port**

operator port1 [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | **inner-source-port** *operator port1* [*port2*] | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner packet information.

17. Create or edit a rule.

- Create or edit a rule for matching non-encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | **logging** | **qos-local-id** *local-id-value* | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

- Create or edit a rule for matching encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } **vxlan** [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | **inner-source-port** *operator port1* [*port2*] | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | **logging** | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner packet information.

18. Create or edit a rule. Choose the options to configure as needed:

- Create or edit a rule for matching non-encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment**

microsegment-id [**mask-length** *mask-length*] | *dest-address dest-wildcard* | **any** } | **destination-port** *operator port1* [*port2*] | { { **precedence** *precedence* | **tos** *tos* } * | { **precedence** *precedence* | **ecn** *ecn* } * | { **dscp** *dscp* | **ecn** *ecn* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | **logging** | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

- Create or edit a rule for matching encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } **vxlan** [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | **inner-source-port** *operator port1* [*port2*] | **logging** | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by outer or inner packet information.

19. Create or edit a rule. Choose the options to configure as needed:

- Create or edit a rule for matching non-encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** *operator port1* [*port2*] | { { **precedence** *precedence* | **tos** *tos* } * | { **precedence** *precedence* | **ecn** *ecn* } * | { **dscp** *dscp* | **ecn** *ecn* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **qos-local-id** *local-id-value* | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

  An IPv4 advanced ACL rule containing the **qos-local-id** keyword cannot be used for outbound QoS traffic classification or outbound packet filtering.

  The VPN instance cannot be matched in the outbound direction.

  In the inbound direction on edge devices in a VXLAN network, the inner header information of VXLAN packets is matched first, and the outer header information is matched if no matched is found in the inner header information. On core devices, only the outer header information of VXLAN packets can be matched.

- Create or edit a rule for matching encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } **vxlan** [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id*] *

inner-protocol *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | **inner-source-port** *operator port1* [*port2*] | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner packet information.

20. Create or edit a rule.

- Create or edit a rule for matching non-encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { { **precedence** *precedence* | **tos** *tos* } * | { **precedence** *precedence* | **ecn** *ecn* } * | { **dscp** *dscp* | **ecn** *ecn* } * } | [**any-fragment** | **first-fragment** | **fragment** | **non-fragment** | **non-or-first-fragment**] | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **qos-local-id** *local-id-value* | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

- Create or edit a rule for matching encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan** | **geneve** } [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | **inner-source-port** *operator port1* [*port2*] | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner packet

	information.
geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

21. Create or edit a rule.

- Create or edit a rule for matching non-encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | *dest-address dest-wildcard* | **any** } | **destination-port** *operator port1* [*port2*] | { { **precedence** *precedence* | **tos** *tos* } * | { **precedence** *precedence* | **ecn** *ecn* } * | { **dscp** *dscp* | **ecn** *ecn* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | **logging** | **qos-local-id** *local-id-value* | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

- Create or edit a rule for matching encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } **vxlan** [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | **inner-source-port** *operator port1* [*port2*] | **logging** | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner packet information.

22. Create or edit a rule.

- Create or edit a rule for matching non-encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { *dest-address dest-wildcard* | **any** } | **destination-port** *operator port1* [*port2*] | { { **precedence** *precedence* | **tos** *tos* } * | { **precedence** *precedence* | **ecn** *ecn* } * | { **dscp** *dscp* | **ecn** *ecn* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | **logging** | **qos-local-id** *local-id-value* | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

- Create or edit a rule for matching encapsulated packets.

rule [*rule-id*] { **deny** | **permit** } **vxlan** [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | **inner-source-port** *operator port1* [*port2*] | **logging** | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner packet information.

23. Create or edit a rule. Choose the options to configure as needed:

- Create or edit a rule for matching non-encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { { **precedence** *precedence* | **tos** *tos* } * | { **precedence** *precedence* | **ecn** *ecn* } * | { **dscp** *dscp* | **ecn** *ecn* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **qos-local-id** *local-id-value* | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

- Create or edit a rule for matching encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan** | **geneve** } [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | **inner-source-port** *operator port1* [*port2*] | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner packet information.
geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

24. Create or edit a rule. Choose the options to configure as needed:

- Create or edit a rule for matching non-encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

- Create or edit a rule for matching encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan** | **geneve** } [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | **inner-source-port** *operator port1* [*port2*] | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner packet information.
geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

25. Create or edit a rule.

rule [*rule-id*] { **deny** | **permit** } *protocol* [**counting** | **destination** { **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { **dscp** *dscp* | **precedence** *precedence* } | [**first-fragment** | **fragment** | **non-fragment** | **non-or-first-fragment**] | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **source** { **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

26. Create or edit a rule.

- Create or edit a rule for matching non-encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **source** { **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

- Create or edit a rule for matching encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan** | **geneve** } [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | { { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | **inner-source-port** *operator port1* [*port2*] | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner packet information.
geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

27. Create or edit a rule.

rule [*rule-id*] { **deny** | **permit** } *protocol* [**counting** | **destination** { **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** }

| **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * } | [**any-fragment** | **first-fragment** | **fragment** | **non-fragment** | **non-or-first-fragment**] | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **source** { **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

28. Create or edit a rule.

rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { { **precedence** *precedence* | **tos** *tos* } * | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

Only the S6813 switch series supports the **microsegment** parameter.

29. Create or edit a rule. Choose the options to configure as needed:

- Create or edit a rule for matching non-encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** } | **destination-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | { { **precedence** *precedence* | **tos** *tos* } * | { **precedence** *precedence* | **ecn** *ecn* } * | { **dscp** *dscp* | **ecn** *ecn* } * } | [**any-fragment** | **first-fragment** | **fragment** | **non-fragment** | **non-or-first-fragment**] | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | [**flow-logging** | **logging**] | **qos-local-id** *local-id-value* | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *source-address source-wildcard* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **time-range** *time-range-name* | **vpn-instance** *vpn-instance-name*] *

- Create or edit a rule for matching encapsulated packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan** | **geneve** } [**destination** { *dest-address dest-wildcard* | **any** } | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-wildcard* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-wildcard* | **any** } | **inner-source-port** *operator port1* [*port2*] | { { **inner-dscp**

inner-dscp | **inner-ecn** *inner-ecn* } * | { **inner-ecn** *inner-ecn* | **inner-precedence** *inner-precedence* } * | { **inner-precedence** *inner-precedence* | **inner-tos** *inner-tos* } * } | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches VXLAN packets by both outer and inner packet information.
geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

The **flow-logging** or **logging** keyword takes effect only when the module (for example, packet filtering) that uses the ACL supports logging.

30. (Optional.) Add or edit a rule comment.

    rule *rule-id* **comment** *text*

    By default, no rule comment is configured.

31. (Optional.) Add a rule remark.

    rule [*rule-id*] **remark** *text*

    By default, no rule remark is configured.

Configuring an IPv6 advanced ACL

1. Enter system view.

   system-view

2. Create an IPv6 advanced ACL and enter its view. Choose one option as needed:
   - Create a numbered IPv6 advanced ACL by specifying an ACL number.

     acl ipv6 number *acl-number* [**name** *acl-name*] [**match-order** { **auto** | **config** }]
   - Create an IPv6 advanced ACL by specifying the **advanced** keyword.

     acl ipv6 advanced { *acl-number* | **name** *acl-name* } [**match-order** { **auto** | **config** }]

3. (Optional.) Configure a description for the IPv6 advanced ACL.

   description *text*

   By default, an IPv6 advanced ACL does not have a description.

4. (Optional.) Set the rule numbering step.

   step *step-value* [**start** *start-value*]

   By default, the rule numbering step is 5 and the start rule ID is 0.

5. Create or edit a rule. Choose the options to configure as needed:
   - Create or edit a rule for matching non-encapsulated packets.

     rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **destination-port** { **object-group**

port-group-name | *operator port1* [*port2*] } | **destination-port** *operator port1* [*port2*] | | { **dscp** *dscp* | **ecn** *ecn-value* } * | **dscp** *dscp* | **dscp** *dscp* | **dscp** *dscp* | **dscp** *dscp* | **dscp** *dscp* | **flow-label** *flow-label-value* | [**any-fragment** | **first-fragment** | **fragment** | **non-fragment** | **non-or-first-fragment**] | **fragment** | [**first-fragment** | **fragment** | **non-fragment** | **non-or-first-fragment**] | **fragment** | **fragment** | **fragment** | **fragment** | **fragment** | **fragment** | **fragment** | **fragment** | **icmp6-type** { *icmp6-type icmp6-code* | *icmp6-message* } | [**flow-logging** | **logging**] | **logging**| | **packet-length** *operator length-value1* [*length-value2*] | **qos-local-id** *local-id-value* | **routing** [**type** *routing-type*] | **hop-by-hop** [**type** *hop-type*] | **source** { **microsegment** *microsegment-id* [**mask-length** *mask-length*] | **object-group** *address-group-name* | *source-address source-prefix* | *source-address/source-prefix* | **any** } | **source-port** { **object-group** *port-group-name* | *operator port1* [*port2*] } | **source-port** *operator port1* [*port2*] | **time-range** *time-range-name*| **user-group** *group-name* | **vpn-instance** *vpn-instance-name*] *

- Create or edit a rule for matching IPv4 VXLAN or Geneve packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan** | **geneve** } [**vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **inner-source-port** *operator port1* [*port2*] | { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | [**flow-logging** | **logging**] | **packet-length** *operator length-value1* [*length-value2*] | **time-range** *time-range-name*] *

- Create or edit a rule for matching IPv4 VXLAN or Geneve packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan** | **geneve** } [**vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **inner-source-port** *operator port1* [*port2*] | { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

- Create or edit a rule for matching IPv4 VXLAN packets.

  rule [*rule-id*] { **deny** | **permit** } **vxlan** [**vxlan-id** *vxlan-id*] **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **inner-source-port** *operator*

port1 [*port2*] | { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | **logging** | **time-range** *time-range-name*] *

- Create or edit a rule for matching IPv4 VXLAN packets.

  rule [*rule-id*] { **deny** | **permit** } **vxlan** [**vxlan-id** *vxlan-id*] **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **inner-source-port** *operator port1* [*port2*] | { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | **logging** | **time-range** *time-range-name*] *

- Create or edit a rule for matching IPv4 VXLAN or Geneve packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan** | **geneve** } [**vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **inner-source-port** *operator port1* [*port2*] | { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | **logging** | **time-range** *time-range-name*] *

- Create or edit a rule for matching IPv4 VXLAN packets.

Parameter	Description
vxlan	Matches IPv4 VXLAN packets by both outer and inner packet information. The following outer header information is not supported for matching IPv4 VXLAN packets: • Outer source IP address. • Outer destination IP address. • Outer source port number. • Outer destination port number.
geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

vxlan-ipv6	Matches IPv6 VXLAN packets by both outer and inner packet information.
geneve-ipv6	Matches IPv6 Geneve packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

- Create or edit a rule for matching IPv6 VXLAN or Geneve packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan-ipv6** | **geneve-ipv6** } [**destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **inner-source-port** *operator port1* [*port2*] | { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches IPv4 VXLAN packets by both outer and inner packet information. The following outer header information is not supported for matching IPv4 VXLAN packets: • Outer source IP address. • Outer destination IP address. • Outer source port number. • Outer destination port number.
geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.
vxlan-ipv6	Matches IPv6 VXLAN packets by both outer and inner packet information.
geneve-ipv6	Matches IPv6 Geneve packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

- Create or edit a rule for matching IPv6 VXLAN or Geneve packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan-ipv6** | **geneve-ipv6** } [**destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol**

inner-protocol [**counting** | **inner-destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **inner-source-port** *operator port1* [*port2*] | { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches IPv4 VXLAN packets by both outer and inner packet information. The following outer header information is not supported for matching IPv4 VXLAN packets: • Outer source IP address. • Outer destination IP address. • Outer source port number. • Outer destination port number.
geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.
vxlan-ipv6	Matches IPv6 VXLAN packets by both outer and inner packet information.
geneve-ipv6	Matches IPv6 Geneve packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

- Create or edit a rule for matching IPv6 VXLAN or Geneve packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan-ipv6** | **geneve-ipv6** } [**destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **inner-destination-port** *operator port1* [*port2*] | { { **inner-ack** *inner-ack-value* | **inner-fin** *inner-fin-value* | **inner-psh** *inner-psh-value* | **inner-rst** *inner-rst-value* | **inner-syn** *inner-syn-value* | **inner-urg** *inner-urg-value* } * | **inner-established** } | **inner-source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **inner-source-port** *operator port1* [*port2*] | { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches IPv4 VXLAN packets by both outer and inner packet information. The following outer header information is not supported for

	matching IPv4 VXLAN packets: • Outer source IP address. • Outer destination IP address. • Outer source port number. • Outer destination port number.
geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.
vxlan-ipv6	Matches IPv6 VXLAN packets by both outer and inner packet information.
geneve-ipv6	Matches IPv6 Geneve packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

- Create or edit a rule for matching IPv6 VXLAN or Geneve packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan-ipv6** | **geneve-ipv6** } [**destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **source-port** *operator port1* [*port2*] | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] * **inner-protocol** *inner-protocol* [**counting** | **inner-destination** { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** } | **inner-destination-port** *operator port1* [*port2*] | **inner-source** { *source-address source-prefix* | *source-address/source-prefix* | **any** } | **inner-source-port** *operator port1* [*port2*] | { **inner-dscp** *inner-dscp* | **inner-ecn** *inner-ecn* } * | [**flow-logging** | **logging**] | **time-range** *time-range-name*] *

Parameter	Description
vxlan	Matches IPv4 VXLAN packets by both outer and inner packet information. The following outer header information is not supported for matching IPv4 VXLAN packets: • Outer source IP address. • Outer destination IP address. • Outer source port number. • Outer destination port number.
geneve	Matches Generic Network Virtualization Encapsulation (Geneve) packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.
vxlan-ipv6	Matches IPv6 VXLAN packets by both outer and inner packet information.
geneve-ipv6	Matches IPv6 Geneve packets. You can specify the **geneve-id** *geneve-id* and **option-header-length** *option-length* options only after you specify this keyword.

The **flow-logging** or **logging** keyword takes effect only when the module (for example, packet filtering) that uses the ACL supports logging.

6. (Optional.) Add or edit a rule comment.

   rule *rule-id* **comment** *text*

   By default, no rule comment is configured.

7. (Optional.) Add a rule remark.

   rule [*rule-id*] **remark** *text*

   By default, no rule remark is configured.

Configuring a Layer 2 ACL

About this task

Layer 2 ACLs can be used in the following scenarios:

- To improve security when the device acts as a Telnet server, you can use Layer 2 ACLs to allow only matching clients to access the server. For more information, see login management in *Fundamentals Configuration Guide*.
- To take different QoS actions on different traffic types, you can use Layer 2 ACLs to classify traffic. For more information about traffic classes, see "Configuring QoS."

Layer 2 ACLs, also called Ethernet frame header ACLs, match packets based on Layer 2 Ethernet header fields, such as:

- Source MAC address.
- Destination MAC address.
- 802.1p priority (VLAN priority).
- Link layer protocol type.
- Encapsulation type.

Procedure

1. Enter system view.

   system-view

2. Create a Layer 2 ACL and enter its view. Choose one option as needed:
   - Create a Layer 2 ACL by specifying an ACL number.

     acl number *acl-number* [**name** *acl-name*] [**match-order** { **auto** | **config** }]
   - Create a Layer 2 ACL by specifying the **mac** keyword.

     acl mac { *acl-number* | **name** *acl-name* } [**match-order** { **auto** | **config** }]

3. (Optional.) Configure a description for the Layer 2 ACL.

   description *text*

   By default, a Layer 2 ACL does not have a description.

4. (Optional.) Set the rule numbering step.

   step *step-value* [**start** *start-value*]

   By default, the rule numbering step is 5 and the start rule ID is 0.

5. Create or edit a rule.
   - Create or edit a rule for matching common packets.

     rule [*rule-id*] { **deny** | **permit** } [**cos** *dot1p* | **counting** | **dest-mac** *dest-address dest-mask* | **type** *protocol-type protocol-type-mask* |

source-mac *source-address source-mask* | **time-range** *time-range-name*] *

- Create or edit a rule for matching VXLAN or Geneve packets.

  rule [*rule-id*] { **deny** | **permit** } { **vxlan** | **geneve** } [**counting** | **dest-mac** *dest-address dest-mask* | **inner-dest-mac** *inner-dest-address inner-dest-mask* | **inner-source-mac** *inner-source-address inner-source-mask* | **inner-type** *inner-protocol-type inner-protocol-type-mask* | **source-mac** *source-address source-mask* | **time-range** *time-range-name* | **type** *protocol-type protocol-type-mask* | **vxlan-id** *vxlan-id* | **geneve-id** *geneve-id* | **option-header-length** *option-length*] *

6. (Optional.) Add or edit a rule comment.

   rule *rule-id* **comment** *text*

   By default, no rule comment is configured.

7. (Optional.) Add a rule remark.

   rule [*rule-id*] **remark** *text*

   By default, no rule remark is configured.

Configuring a user-defined ACL

About this task

User-defined ACLs allow you to customize rules based on information in protocol headers. You can define a user-defined ACL to match packets. A specific number of bytes after an offset (relative to the specified header) are compared against a match pattern after being ANDed with a match pattern mask.

Procedure

1. Enter system view.

   system-view

2. Create a user-defined ACL and enter its view. Choose one option as needed:

   - Create a user-defined ACL by specifying an ACL number.

     acl number *acl-number* [**name** *acl-name*]

   - Create a user-defined ACL by specifying the **user-defined** keyword.

     acl user-defined { *acl-number* | **name** *acl-name* }

3. (Optional.) Configure a description for the user-defined ACL.

   description *text*

   By default, a user-defined ACL does not have a description.

4. Create or edit a rule.

   Command set 1:

   rule [*rule-id*] { **deny** | **permit** } [{ { **ipv4** | **ipv6** | **l2** | **l4** } *rule-string rule-mask offset* }&<1-8>] [**counting** | **time-range** *time-range-name*] *

   Command set 2:

   rule [*rule-id*] { **deny** | **permit** } [**ipv6-protocol**] *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **destination** { **object-group** *address-group-name* | *dest-address dest-wildcard* | **any** | **microsegment** *microsegment-id* [**mask-length** *mask-length*] } | **destination-port** { *operator port1* [*port2*] } | { { **precedence** *precedence* | **tos** *tos* } * | **dscp**

dscp } | **source** { **object-group** *address-group-name* | *source-address source-wildcard* | **any** | **microsegment** *microsegment-id* [**mask-length** *mask-length*] } } | **source-port** { *operator port1* [*port2*] } | **vpn-instance** *vpn-instance-name*] * [{ { **ipv4** | **ipv6** | **l2** | **l4** } *rule-string rule-mask offset* }&<1-8>] [**counting** | **time-range** *time-range-name*] *

5. (Optional.) Add or edit a rule comment.

   rule *rule-id* **comment** *text*

   By default, no rule comment is configured.

6. (Optional.) Add a rule remark.

   rule [*rule-id*] **remark** *text*

   By default, no rule remark is configured.

Copying an ACL

About this task

You can create an ACL by copying an existing ACL (source ACL). The new ACL (destination ACL) has the same properties and content as the source ACL, but uses a different number or name than the source ACL.

Restrictions and guidelines

To successfully copy an ACL, make sure:

- The destination ACL is the same type as the source ACL.
- The source ACL already exists, but the destination ACL does not.

Procedure

1. Enter system view.

   system-view

2. Copy an existing ACL to create a new ACL.

   acl [**ipv6** | **mac** | **user-defined**] **copy** { *source-acl-number* | **name** *source-acl-name* } **to** { *dest-acl-number* | **name** *dest-acl-name* }

Configuring the QoS and ACL resource hardware mode

About this task

Different chips produce different packet matching results for QoS and ACL resources. Perform this task to enhance matching capabilities of QoS and ACL resources.

Restrictions and guidelines

This feature occupies more QoS and ACL resources when an ACL is applied.

Procedure

1. Enter system view.

   system-view

2. Configure the QoS and ACL resource hardware mode.

   qos-acl resource hardware-mode *hardware-mode-value*

   By default, no QoS and ACL resource hardware mode is configured.

Configuring packet filtering with ACLs

About packet filtering with ACLs

This section describes procedures for using an ACL to filtering packets. For example, you can apply an ACL to an interface to filter incoming or outgoing packets.

Applying an ACL to filter packets globally

Restrictions and guidelines

If you apply an exact-match ACL to filter packets globally, do not set the packet filtering default action to deny.

Procedure

1. Enter system view.

   system-view

2. Apply an ACL globally.

   packet-filter [**ipv6** | **mac** | **user-defined**] { *acl-number* | **name** *acl-name* } **global** { **inbound** [**exact-match**] | **outbound** } [**hardware-count**]

   By default, global packet filtering is not configured.

Applying an ACL to an interface for packet filtering

Restrictions and guidelines

A VLAN interface does not support using IPv4 ACL rules configured with the **vpn-instance** parameter to filter packets.

When an ACL is applied to the inbound direction of an interface for packet filtering, the ACL cannot match the destination MAC address or customer VLAN field of IPv4 VXLAN packets.

The following interfaces do not support using IPv4 ACL rules configured with the **vpn-instance** parameter to filter packets:

- Layer 3 Ethernet interface/subinterfaces.
- Layer 3 aggregate interface/subinterfaces.

An ACL applied to the outbound direction of a VLAN interface cannot match untagged packets.

The following restrictions apply to the **extend** keyword:

- If equal-cost routes exist from the device to the network accessed through a VLAN interface, the VLAN interface does not support the **extend** keyword.
- support the **extend** keyword only on VLAN interfaces.
- The packet filtering feature that uses expanded ACL resources and the microsegmentation feature are mutually exclusive in the outbound direction of the same VLAN interface. If you have configured one feature in the outbound direction of a VLAN interface, the other feature cannot take effect in the same direction of the VLAN interface.
- The packet filtering feature on a VLAN interface that uses expanded ACL resources and the **packet-filter filter all** command are mutually exclusive.
- If you apply an ACL to the outbound direction of a VLAN interface with the keyword and execute the **packet-filter default deny** command, the deny action takes effect on only Layer 3 packets on that VLAN interface.

If you apply an exact-match ACL to filter packets globally, do not set the packet filtering default action to deny.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Apply an ACL to the interface to filter packets.

   packet-filter [**ipv6** | **mac** | **user-defined**] { *acl-number* | **name** *acl-name* } { **inbound** [**exact-match**] | **outbound** [**extend**] } [**hardware-count**]

   By default, an interface does not filter packets.

Configuring the applicable scope of packet filtering on a VLAN interface

About this task

You can configure the packet filtering on a VLAN interface to filter the following packets:

- Packets forwarded at Layer 3 by the VLAN interface.
- All packets, including packets forwarded at Layer 3 by the VLAN interface and packets forwarded at Layer 2 by the physical ports associated with the VLAN interface.

Procedure

1. Enter system view.

   system-view

2. Create a VLAN interface and enter its view.

   interface vlan-interface *vlan-interface-id*

   If the VLAN interface already exists, you directly enter its view.

   By default, no VLAN interface exists.

3. Specify the applicable scope of packet filtering on the VLAN interface.

   packet-filter filter [**route** | **all**]

   By default, the packet filtering filters packets forwarded at Layer 3.

Configuring logging and SNMP notifications for packet filtering

About this task

You can configure the ACL module to generate log entries or SNMP notifications for packet filtering and output them to the information center or SNMP module at the output interval. When the first packet of a flow matches an ACL rule, the output interval starts. At the end of the interval, the device outputs a log entry or notification to record the number of matching packets and the matched ACL rule during the interval.

For more information about the information center and SNMP, see *Network Management and Monitoring Configuration Guide.*

Procedure

1. Enter system view.

system-view

2. Set the interval for outputting packet filtering logs or notifications.

   acl { **logging** | **trap** } **interval** *interval*

   The default setting is 0 minutes. By default, the device does not generate log entries or SNMP notifications for packet filtering.

Setting the packet filtering default action

1. Enter system view.

   system-view

2. Set the packet filtering default action to deny.

   packet-filter default deny

   By default, the packet filter permits packets that do not match any ACL rule to pass.

Configuring an EM template and its match criteria

About this task

An exact match (EM) template is a template of match criteria. It can be used to match the match criteria in a QoS policy or packet filter, match criteria configured by using the **rule** command in an ACL, or match criteria configured by using the **if-match** command in QoS traffic class view. When the preceding match criteria separately correspond to the match criteria configured by using the **exact-match** command in EM template view, the service module will use EM resources to match and process packets. EM resources are forwarding entry resources of a device, and are stored in the same hardware storage space as MAC address entries and route entries. By using EM resources to match and process packets, you can increase the number of match criteria supported by the device.

To use this feature in a service module, reference an EM template in the service module. A service module referencing an EM template can use EM resources to process the specified match criteria.

Restrictions and guidelines

In the current software version, only the QoS policy and packet filter service modules support this feature. For information about referencing EM templates in a service module, see *ACL and QoS Command Reference* or "Configuring packet filtering with ACLs".

If an EM template has been referenced by a service module, you cannot modify or delete match criteria in the EM template. To do that, first remove the EM template from the service module.

Procedure

1. Enter system view.

   system-view

2. Create an EM template and enter its view.

   acl exact-match template *template-id*

   By default, no EM templates exists.

3. Configure match criteria in the EM template.

   exact-match { **ipv4** | **ipv6** } { **destination-ip** | **destination-port** | **protocol** | **source-ip** | **source-port** } *

   By default, no match criteria are configured in an EM template.

Display and maintenance commands for ACL

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display ACL configuration and match statistics.	**display acl** [**ipv6** | **mac** | **user-defined**] { *acl-number* | **all** | **name** *acl-name* }
Display ACL application information for packet filtering.	**display packet-filter** { **global** | **interface** [*interface-type interface-number*] } [**inbound** | **outbound**] [**slot** *slot-number*]
Display match statistics for packet filtering ACLs.	**display packet-filter statistics** { **global** | **interface** *interface-type interface-number* } { **inbound** | **outbound** } [[**ipv6** | **mac** | **user-defined**] { *acl-number* | **name** *acl-name* }] [**brief**]
Display the accumulated statistics for packet filtering ACLs.	**display packet-filter statistics sum** { **inbound** | **outbound** } [**ipv6** | **mac** | **user-defined**] { *acl-number* | **name** *acl-name* } [**brief**]
Display detailed ACL packet filtering information.	**display packet-filter verbose** { **global** | **interface** *interface-type interface-number* } { **inbound** | **outbound** } [[**ipv6** | **mac** | **user-defined**] { *acl-number* | **name** *acl-name* }] [**slot** *slot-number*]
Display QoS and ACL resource usage.	**display qos-acl resource** [**slot** *slot-number*]
Clear ACL statistics.	**reset acl** [**ipv6** | **mac** | **user-defined**] **counter** { *acl-number* | **all** | **name** *acl-name* }
Display the configuration and state of an applied EM template.	**display acl exact-match template** [*template-id*] [**slot** *slot-number*]
Clear match statistics for packet filtering ACLs.	**reset packet-filter statistics** { **global** | **interface** [*interface-type interface-number*] } { **inbound** | **outbound** } [[**ipv6** | **mac** | **user-defined**] { *acl-number* | **name** *acl-name* }]

ACL configuration examples

Example: Configuring interface-based packet filter

Network configuration

A company interconnects its departments through the device. Configure a packet filter to:

- Permit access from the President's office at any time to the financial database server.
- Permit access from the Finance department to the database server only during working hours (from 8:00 to 18:00) on working days.
- Deny access from any other department to the database server.

Figure 1 Network diagram

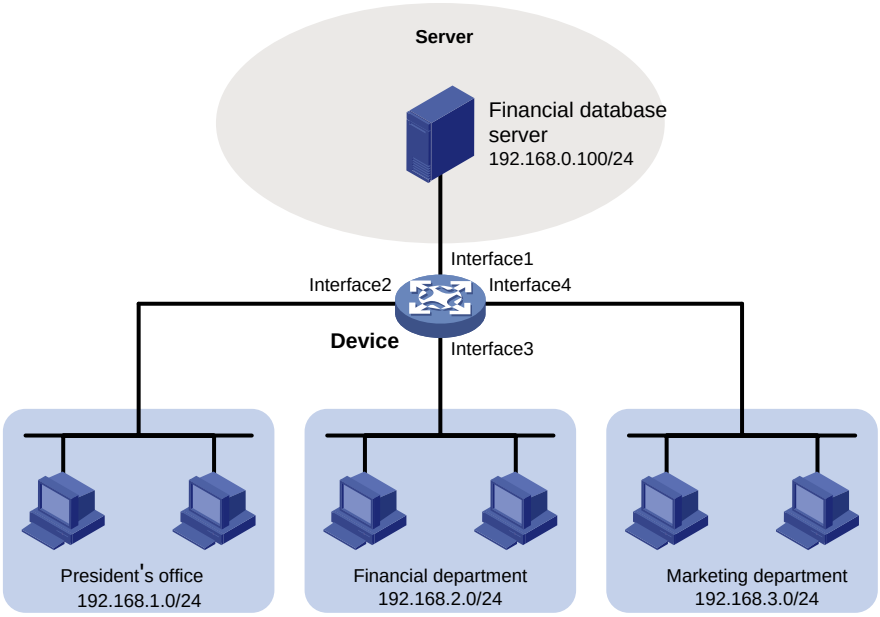

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4

Procedure

Create a periodic time range from 8:00 to 18:00 on working days.

```
<Device> system-view
[Sysname] sysname Device
[Device] time-range work 08:0 to 18:00 working-day
```

Assign IP addresses to interfaces.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip address 192.168.0.1 24
[Device-GigabitEthernet1/0/1] quit
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] ip address 192.168.1.1 24
[Device-GigabitEthernet1/0/2] quit
[Device] interface gigabitethernet 1/0/3
[Device-GigabitEthernet1/0/3] ip address 192.168.2.1 24
[Device-GigabitEthernet1/0/3] quit
[Device] interface gigabitethernet 1/0/4
[Device-GigabitEthernet1/0/4] ip address 192.168.3.1 24
[Device-GigabitEthernet1/0/4] quit
```

Configure IS-IS.

```
[Device] isis 1
```

```
[Device-isis-1] network-entity 00.0000.0000.0001.00
[Device-isis-1] is-level level-2
[Device-isis-1] cost-style wide
[Device-isis-1] address-family ipv4
[Device-isis-1-ipv4] quit
[Device-isis-1] quit
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] isis enable 1
[Device-GigabitEthernet1/0/1] quit
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] isis enable 1
[Device-GigabitEthernet1/0/2] quit
[Device] interface gigabitethernet 1/0/3
[Device-GigabitEthernet1/0/3] isis enable 1
[Device-GigabitEthernet1/0/3] quit
[Device] interface gigabitethernet 1/0/4
[Device-GigabitEthernet1/0/4] isis enable 1
[Device-GigabitEthernet1/0/4] quit
```

Create an IPv4 advanced ACL numbered 3000.

```
[Device] acl advanced 3000
```

Configure a rule to permit access from the President's office to the financial database server.

```
[Device-acl-ipv4-adv-3000] rule permit ip source 192.168.1.0 0.0.0.255 destination
192.168.0.100 0
```

Configure a rule to permit access from the Finance department to the database server during working hours.

```
[Device-acl-ipv4-adv-3000] rule permit ip source 192.168.2.0 0.0.0.255 destination
192.168.0.100 0 time-range work
```

Configure a rule to deny access to the financial database server.

```
[Device-acl-ipv4-adv-3000] rule deny ip source any destination 192.168.0.100 0
[Device-acl-ipv4-adv-3000] quit
```

Apply IPv4 advanced ACL 3000 to filter outgoing packets on interface GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] packet-filter 3000 outbound
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify that a PC in the Finance department can ping the database server during working hours. (All PCs in this example use Windows XP).

```
C:\> ping 192.168.0.100

Pinging 192.168.0.100 with 32 bytes of data:

Reply from 192.168.0.100: bytes=32 time=1ms TTL=255
Reply from 192.168.0.100: bytes=32 time<1ms TTL=255
Reply from 192.168.0.100: bytes=32 time<1ms TTL=255
Reply from 192.168.0.100: bytes=32 time<1ms TTL=255

Ping statistics for 192.168.0.100:
```

```
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 0ms, Maximum = 1ms, Average = 0ms
```

Verify that a PC in the Marketing department cannot ping the database server during working hours.

```
C:\> ping 192.168.0.100

Pinging 192.168.0.100 with 32 bytes of data:

Request timed out.
Request timed out.
Request timed out.
Request timed out.

Ping statistics for 192.168.0.100:
    Packets: Sent = 4, Received = 0, Lost = 4 (100% loss),
```

Display configuration and match statistics for IPv4 advanced ACL 3000 on the device during working hours.

```
[Device] display acl 3000
Advanced IPv4 ACL 3000, 3 rules,
ACL's step is 5
 rule 0 permit ip source 192.168.1.0 0.0.0.255 destination 192.168.0.100 0
 rule 5 permit ip source 192.168.2.0 0.0.0.255 destination 192.168.0.100 0 time-range work (Active)
 rule 10 deny ip destination 192.168.0.100 0
```

The output shows that rule 5 is active. Rule 5 and rule 10 have been matched four times as the result of the ping operations.

Configuration files

```
#
 sysname Device

QoS overview

In data communications, Quality of Service (QoS) provides differentiated service guarantees for diversified traffic in terms of bandwidth, delay, jitter, and drop rate, all of which can affect QoS.

QoS manages network resources and prioritizes traffic to balance system resources.

The following section describes typical QoS service models and widely used QoS techniques.

QoS service models

This section describes several typical QoS service models.

Best-effort service model

The best-effort model is a single-service model. The best-effort model is not as reliable as other models and does not guarantee delay-free delivery.

The best-effort service model is the default model for the Internet and applies to most network applications. It uses the First In First Out (FIFO) queuing mechanism.

IntServ model

The integrated service (IntServ) model is a multiple-service model that can accommodate diverse QoS requirements. This service model provides the most granularly differentiated QoS by identifying and guaranteeing definite QoS for each data flow.

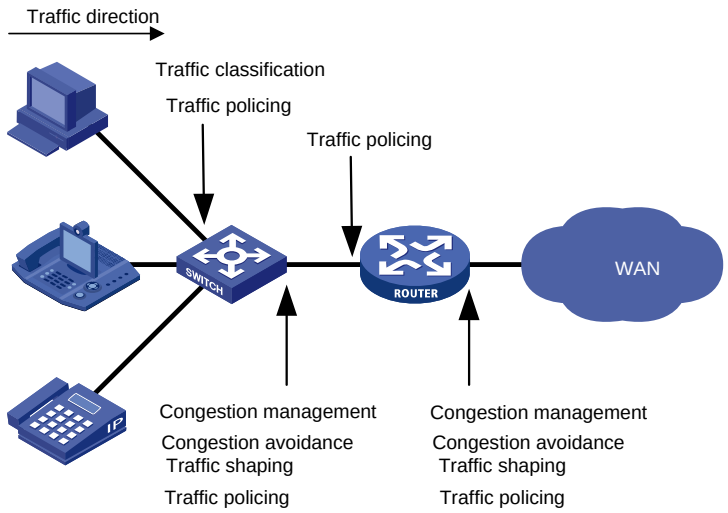
In the IntServ model, an application must request service from the network before it sends data. IntServ signals the service request with the RSVP. All nodes receiving the request reserve resources as requested and maintain state information for the application flow.

The IntServ model demands high storage and processing capabilities because it requires all nodes along the transmission path to maintain resource state information for each flow. This model is suitable for small-sized or edge networks. However, it is not suitable for large-sized networks, for example, the core layer of the Internet, where billions of flows are present.

DiffServ model

The differentiated service (DiffServ) model is a multiple-service model that can meet diverse QoS requirements. It is easy to implement and extend. DiffServ does not signal the network to reserve resources before sending data, as IntServ does.

QoS techniques in a network



The QoS techniques include the following features:

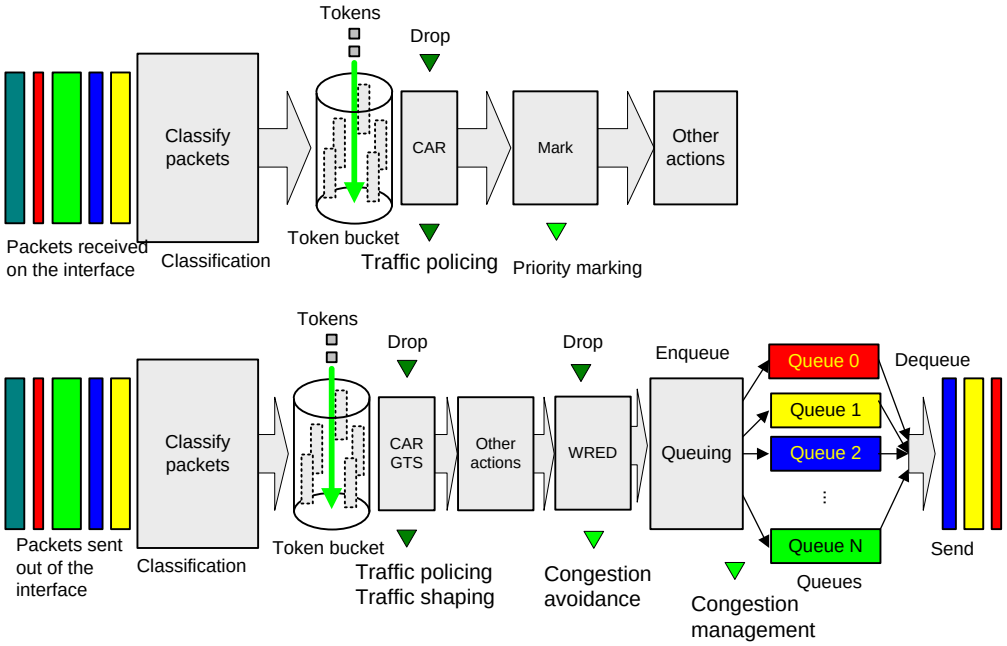
- Traffic classification.
- Traffic policing.
- Traffic shaping.
- Rate limit.
- Congestion management.
- Congestion avoidance.

The following section briefly introduces these QoS techniques.

All QoS techniques in this document are based on the DiffServ model.

Figure 1 Position of the QoS techniques in a network

As shown in Figure 1, traffic classification, traffic shaping, traffic policing, congestion management, and congestion avoidance mainly implement the following functions:



- **Traffic classification**—Uses match criteria to assign packets with the same characteristics to a traffic class. Based on traffic classes, you can provide differentiated services.
- **Traffic policing**—Polices flows and imposes penalties to prevent aggressive use of network resources. You can apply traffic policing to both incoming and outgoing traffic of a port.
- **Traffic shaping**—Adapts the output rate of traffic to the network resources available on the downstream device to eliminate packet drops. Traffic shaping usually applies to the outgoing traffic of a port.
- **Congestion management**—Provides a resource scheduling policy to determine the packet forwarding sequence when congestion occurs. Congestion management usually applies to the outgoing traffic of a port.
- **Congestion avoidance**—Monitors the network resource usage. It is usually applied to the outgoing traffic of a port. When congestion worsens, congestion avoidance reduces the queue length by dropping packets.

QoS processing flow in a device

Figure 2 briefly describes how the QoS module processes traffic.

1. Traffic classifier identifies and classifies traffic for subsequent QoS actions.
2. The QoS module takes various QoS actions on classified traffic as configured, depending on the traffic processing phase and network status. For example, you can configure the QoS module to perform the following operations:
   - Traffic policing for incoming traffic.
   - Traffic shaping for outgoing traffic.
   - Congestion avoidance before congestion occurs.
   - Congestion management when congestion occurs.

Figure 2 QoS processing flow

QoS configuration approaches

You can configure QoS by using the MQC approach or non-MQC approach.

In the modular QoS configuration (MQC) approach, you configure QoS service parameters by using QoS policies. A QoS policy defines QoS actions to take on different classes of traffic and can be applied to an object (such as an interface) to control traffic.

In the non-MQC approach, you configure QoS service parameters without using a QoS policy. For example, you can use the rate limit feature to set a rate limit on an interface without using a QoS policy.

Configuring a QoS policy

About QoS policies

A QoS policy has the following components:

- **Traffic class**—Defines criteria to match packets.
- **Traffic behavior**—Defines QoS actions to take on matching packets.

By associating a traffic class with a traffic behavior, a QoS policy can perform the QoS actions on matching packets.

A QoS policy can have multiple class-behavior associations.

QoS policy tasks at a glance

To configure a QoS policy, perform the following tasks:

1. Defining a traffic class
2. Defining a traffic behavior
3. Defining a QoS policy
4. Applying the QoS policy
   - Applying the QoS policy to an Ethernet service instance
   - Applying the QoS policy to an interface
   - Applying the QoS policy to VLANs
   - Applying the QoS policy globally
   - Applying the QoS policy to a control plane
   - Applying the QoS policy in control-plane management view

Defining a traffic class

Restrictions and guidelines

A match criterion without IPv6 attributes cannot match IPv6 packets.

Procedure

1. Enter system view.
   system-view
2. Create a traffic class and enter traffic class view.
   traffic classifier *classifier-name* [**operator** { **and** | **or** }]
3. (Optional.) Configure a description for the traffic class.
   description *text*

   By default, no description is configured for a traffic class.
4. Configure a match criterion.
   if-match *match-criteria*

   By default, no match criterion is configured.

   For more information, see the **if-match** command in *ACL and QoS Command Reference*.

Defining a traffic behavior

1. Enter system view.

   system-view
2. Create a traffic behavior and enter traffic behavior view.

   traffic behavior *behavior-name*
3. Configure an action in the traffic behavior.

   By default, no action is configured for a traffic behavior.

   For more information about configuring an action, see the subsequent chapters for traffic policing, traffic filtering, priority marking, class-based accounting, and so on.

Defining a QoS policy

1. Enter system view.

   system-view
2. Create a QoS policy and enter QoS policy view.

   qos [**ipv6-matching** | **accounting** | **mirroring** | **remarking** | **tcp-erspan** | **exact-matching**] **policy** *policy-name*

Parameter	Description
ipv6-matching	Represents an IPv6-matching QoS policy.
accounting	Represents an accounting-type QoS policy.
mirroring	Represents a mirroring-type QoS policy.
remarking	Represents a marking-type QoS policy.
tcp-erspan	Represents a TCP ERSPAN-type QoS policy.
exact-matching	Represents an exact-matching QoS policy.

3. Associate a traffic class with a traffic behavior to create a class-behavior association in the QoS policy.

   classifier *classifier-name* **behavior** *behavior-name* [**insert-before** *before-classifier-name*]

   By default, a traffic class is not associated with a traffic behavior.

Applying the QoS policy

Application destinations

You can apply a QoS policy to the following destinations:

- **Ethernet service instance**—The QoS policy can be applied to the traffic received on the Ethernet service instance.
- **Interface**—The QoS policy can be applied to the traffic sent or received on the interface.
- **VLAN**—The QoS policy can be applied to the traffic sent or received on all ports in the VLAN.

- **Globally**—The QoS policy can be applied to the traffic sent or received on all ports.
- **Control plane**—The QoS policy can be applied to the traffic received on the control plane.
- **Management interface control plane**—The QoS policy can be applied to the traffic sent from the management interface to the control plane.

Restrictions and guidelines for applying a QoS policy

You can modify traffic classes, traffic behaviors, and class-behavior associations in a QoS policy even after it is applied (except that it is applied to a user profile). If a traffic class uses an ACL for traffic classification, you can delete or modify the ACL.

If a traffic behavior is configured with multiple actions and one of these actions does not take effect, the whole class-behavior association does not take effect.

A QoS policy applied in control-plane management view does not support matching the following protocols in a traffic class: ARP-snooping, bfd, dhcp, dhcp-snooping, dhcp6, dot1x, lacp, mvrp, oam, portal, pvst, rrpp, smart-link, stp, udp-helper, lldp.

When a QoS policy containing a CAR action is applied on an IRF fabric, the traffic matching the QoS policy might enter the IRF fabric through interfaces on different IRF member devices. In this case, the actual rate limit that takes effect is the sum of the CIR and PIR in the CAR action multiplied by the number of involved IRF member devices by default.

Applying the QoS policy to an Ethernet service instance

Restrictions and guidelines

For configuration commands for Ethernet service instances, see MPLS L2VPN or VPLS in *MPLS Command Reference* or see *VXLAN Command Reference*.

A maximum of five QoS policies (one for each type) can be applied to an Ethernet service instance. Different actions can be taken on the same traffic class if QoS policies of different types are applied to an Ethernet service instance. This rule applies to the devices that support the five QoS policy types: IPv6-matching, accounting, marking, mirroring, and generic.

If you specify the **longest-match** keyword, the system first matches the traffic class with a source or destination address with the longest mask and takes the actions in the associated traffic behavior. Suppose three class-behavior associations are configured in a QoS policy. ACL 3001 in the traffic class of the first class-behavior association is not configured with a source or destination address. ACL 3002 in the traffic class of the second class-behavior association is configured with destination address 10.10.10.0/24. ACL 3003 in the traffic class of the third class-behavior association is configured with destination address 10.10.10.10/32. The match order of the three class-behavior associations is the third class-behavior association, the second class-behavior association, the first class-behavior association. If both source and destination addresses exist in ACLs of different traffic classes, the system matches destination addresses before matching source addresses.

Procedure

1. Enter system view.

   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   - Enter Layer 2 Ethernet interface view:
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view:
     interface bridge-aggregation *interface-number*
3. Create an Ethernet service instance and enter Ethernet service instance view.

   service-instance *instance-id*

4. Apply the QoS policy to the Ethernet service instance.

   qos apply [**ipv6-matching** | **accounting** | **mirroring** | **remarking**] **policy** *policy-name* **inbound** [**longest-match**]

   By default, no QoS policy is applied to an Ethernet service instance.

Applying the QoS policy to an interface

Restrictions and guidelines

A QoS policy can be applied to multiple interfaces. However, only one QoS policy can be applied to one direction (inbound or outbound) of an interface.

A maximum of seven QoS policies (one for each type) can be applied to one direction of an interface. Different actions can be taken on the same traffic class if QoS policies of different types are applied to an interface.

The QoS policy applied to the outgoing traffic on an interface does not regulate local packets. Local packets refer to critical protocol packets sent by the local system for operation maintenance. The most common local packets include link maintenance, RIP, and SSH packets.

If you specify the **longest-match** keyword, the system first matches the traffic class with a source or destination address with the longest mask and takes the actions in the associated traffic behavior. Suppose three class-behavior associations are configured in a QoS policy. ACL 3001 in the traffic class of the first class-behavior association is not configured with a source or destination address. ACL 3002 in the traffic class of the second class-behavior association is configured with destination address 10.10.10.0/24. ACL 3003 in the traffic class of the third class-behavior association is configured with destination address 10.10.10.10/32. The match order of the three class-behavior associations is the third class-behavior association, the second class-behavior association, the first class-behavior association. If both source and destination addresses exist in ACLs of different traffic classes, the system matches destination addresses before matching source addresses.

When a QoS policy is applied to the inbound direction of an interface, it cannot match the destination MAC address or customer VLAN field of IPv4 VXLAN packets.

An ACL rule containing the **vpn-instance** parameter is not supported in a QoS policy applied to an interface.

A QoS policy cannot be applied to the outbound direction of a VSI interface.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Apply the QoS policy to the interface.

   qos apply [**ipv6-matching** | **accounting** | **mirroring** | **remarking** | **tcp-erspan** | **exact-matching**] **policy** *policy-name* { **inbound** | **outbound** [**longest-match**]

   By default, no QoS policy is applied to an interface.

Applying the QoS policy to VLANs

About this task

You can apply a QoS policy to VLANs to regulate the traffic on all ports of the VLANs.

Restrictions and guidelines

QoS policies cannot be applied to dynamic VLANs, including VLANs created by GVRP.

If you specify the **longest-match** keyword, the system first matches the traffic class with a source or destination address with the longest mask and takes the actions in the associated traffic behavior. Suppose three class-behavior associations are configured in a QoS policy. ACL 3001 in the traffic class of the first class-behavior association is not configured with a source or destination address. ACL 3002 in the traffic class of the second class-behavior association is configured with destination address 10.10.10.0/24. ACL 3003 in the traffic class of the third class-behavior association is configured with destination address 10.10.10.10/32. The match order of the three class-behavior associations is the third class-behavior association, the second class-behavior association, the first class-behavior association. If both source and destination addresses exist in ACLs of different traffic classes, the system matches destination addresses before matching source addresses.

When you apply a QoS policy to VLANs, the QoS policy is applied to the specified VLANs on all IRF member devices. If the hardware resources of an IRF member device are insufficient, applying a QoS policy to VLANs might fail on the IRF member device. The system does not automatically roll back the QoS policy configuration already applied to other IRF member devices. To ensure consistency, use the **undo qos vlan-policy vlan** command to manually remove the QoS policy configuration applied to them.

Procedure

1. Enter system view.

   system-view

2. Apply the QoS policy to VLANs.

   qos vlan-policy *policy-name* **vlan** *vlan-id-list* { **inbound** | **outbound** } [**longest-match**]

   By default, no QoS policy is applied to a VLAN.

Applying the QoS policy globally

About this task

You can apply a QoS policy globally to the inbound or outbound direction of all ports.

Restrictions and guidelines

If you do not specify the **longest-match** keyword, the system matches traffic against traffic classes in the order class-behavior associations are configured. When the traffic matches a traffic class, the matching process stops, and the actions in the associated traffic behavior are taken on the matching traffic.

If you specify the **longest-match** keyword, the system first matches the traffic class with a source or destination address with the longest mask and takes the actions in the associated traffic behavior. Suppose three class-behavior associations are configured in a QoS policy. ACL 3001 in the traffic class of the first class-behavior association is not configured with a source or destination address. ACL 3002 in the traffic class of the second class-behavior association is configured with destination address 10.10.10.0/24. ACL 3003 in the traffic class of the third class-behavior association is configured with destination address 10.10.10.10/32. The match order of the three class-behavior associations is the third class-behavior association, the second class-behavior association, the first class-behavior association. If both source and destination addresses exist in ACLs of different traffic classes, the system matches destination addresses before matching source addresses.

If the hardware resources of an IRF member device are insufficient, applying a QoS policy globally might fail on the IRF member device. The system does not automatically roll back the QoS policy configuration already applied to other IRF member devices. To ensure consistency, you must use the **undo qos apply policy global** command to manually remove the QoS policy configuration applied to them.

Procedure

1. Enter system view.

   system-view

2. Apply the QoS policy globally.

   qos apply [**ipv6-matching** | **accounting** | **mirroring** | **remarking** | **tcp-erspan** | **exact-matching**] **policy** *policy-name* **global** { **inbound** | **outbound** } [**longest-match**]

   By default, no QoS policy is applied globally.

Applying the QoS policy to a control plane

About this task

A device provides the user plane and the control plane.

- **User plane**—The units at the user plane are responsible for receiving, transmitting, and switching (forwarding) packets, such as various dedicated forwarding chips. They deliver super processing speeds and throughput.
- **Control plane**—The units at the control plane are processing units running most routing and switching protocols. They are responsible for protocol packet resolution and calculation, such as CPUs. Compared with user plane units, the control plane units allow for great packet processing flexibility but have lower throughput.

When the user plane receives packets that it cannot recognize or process, it transmits them to the control plane. If the transmission rate exceeds the processing capability of the control plane, the control plane will be busy handling undesired packets. As a result, the control plane will fail to handle legitimate packets correctly or timely. As a result, protocol performance is affected.

To address this problem, apply a QoS policy to the control plane to take QoS actions, such as traffic filtering or traffic policing, on inbound traffic. This ensures that the control plane can correctly receive, transmit, and process packets.

A predefined control plane QoS policy uses the protocol type or protocol group type to identify the type of packets sent to the control plane. You can use protocol types or protocol group types in **if-match control-plane** commands in traffic class view for traffic classification. Then you can reconfigure traffic behaviors for these traffic classes as required. You can use the **display qos policy control-plane pre-defined** command to display predefined control plane QoS policies.

Procedure

1. Enter system view.

   system-view

2. Enter control plane view.

   control-plane slot *slot-number*

3. Apply the QoS policy to the control plane.

   qos apply policy *policy-name* **inbound**

   By default, no QoS policy is applied to a control plane.

Applying the QoS policy in control-plane management view

About this task

If the rate of packets from the management interface to the control plane exceeds the processing capability, the control plane will fail to handle the packets correctly or timely. As a result, protocol performance is affected.

This feature allows you to rate limit the packets sent from the management interface to the control plane. This ensures that the control plane can correctly receive, transmit, and process packets from the management interface.

By default, a predefined QoS policy is applied in control-plane management view. To display the predefined QoS policy, use the **display qos policy control-plane management pre-defined** command. The predefined QoS policy uses the protocol type or protocol group type to identify the type of packets sent from the management interface to the control plane. You can use protocol types or protocol group types in **if-match** commands in traffic class view for traffic classification. Then, you can reconfigure traffic behaviors for these traffic classes as required.

Procedure

1. Enter system view.
   system-view
2. Enter control-plane management view.
   control-plane management
3. Apply the QoS policy.
   qos apply policy *policy-name* **inbound**
   By default, no QoS policy is applied in control-plane management view.

Enabling SNMP notifications for QoS

About this task

To report critical QoS events to an SNMP NMS, enable SNMP notifications for QoS.

For QoS notifications to be sent correctly, you must also configure SNMP on the device. For more information about configuring SNMP, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for QoS.
   snmp-agent trap enable qos
   By default, SNMP notifications are disabled for QoS.

Display and maintenance commands for QoS policies

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display QoS policy configuration.	**display qos policy user-defined** [**ipv6-matching** | **accounting** | **mirroring** | **remarking** | **tcp-erspan** | **exact-matching**] [*policy-name* [**classifier** *classifier-name*]] [**slot** *slot-number*]
Display information about QoS policies applied to the control plane.	**display qos policy control-plane slot** *slot-number*

Task	Command
Display information about QoS policies applied in control-plane management view.	**display qos policy control-plane management**
Display information about the predefined QoS policy applied in control-plane management view.	**display qos policy control-plane management pre-defined**
Display information about the predefined QoS policy applied to the control plane.	**display qos policy control-plane pre-defined** [**slot** *slot-number*]
Display information about QoS policies applied globally.	**display qos** [**ipv6-matching** | **accounting** | **mirroring** | **remarking** | **tcp-erspan** | **exact-matching**] **policy global** [**slot** *slot-number*] [**inbound** | **outbound**]
Display information about QoS policies applied to interfaces.	**display qos** [**ipv6-matching** | **accounting** | **mirroring** | **remarking** | **tcp-erspan** | **exact-matching**] **policy interface** [*interface-type interface-number*] [**inbound** | **outbound**]
Display information about QoS policies applied to Ethernet service instances.	**display qos** [**ipv6-matching** | **accounting** | **mirroring** | **remarking**] **policy l2vpn-ac** [**interface** *interface-type interface-number* [**service-instance** *instance-id*] [**slot** *slot-number*]] [**inbound**]
Display information about QoS policies applied to VLANs.	**display qos vlan-policy** { **name** *policy-name* | **vlan** [*vlan-id*] } [**slot** *slot-number*] [**inbound** | **outbound**]
Display QoS and ACL resource usage.	**display qos-acl resource** [**slot** *slot-number*]
Display traffic behavior configuration.	**display traffic behavior user-defined** [*behavior-name*] [**slot** *slot-number*]
Display traffic class configuration.	**display traffic classifier user-defined** [*classifier-name*] [**slot** *slot-number*]
Display statistics for the QoS policy applied to a control plane.	**display qos policy control-plane slot** *slot-number* **rule-statistics**
Display statistics for QoS policies applied globally.	**display qos** [**ipv6-matching** | **accounting** | **mirroring** | **remarking** | **tcp-erspan** | **exact-matching**] **policy global** [**slot** *slot-number*] [**inbound** | **outbound**] **rule-statistics**
Display statistics for QoS policies applied to interfaces.	**display qos** [**ipv6-matching** | **accounting** | **mirroring** | **remarking** | **tcp-erspan** | **exact-matching**] **policy interface** [*interface-type interface-number*] [**slot** *slot-number*] [**inbound** | **outbound**] **rule-statistics**
Display statistics for QoS policies applied to Ethernet service instances.	**display qos** [**ipv6-matching** | **accounting** | **mirroring** | **remarking**] **policy l2vpn-ac** [**interface** *interface-type interface-number*

Task	Command
	[**service-instance** *instance-id*] [**slot** *slot-number*]] [**inbound**] **rule-statistics**
Display statistics for QoS policies applied to VLANs.	**display qos vlan-policy vlan** [*vlan-id*] [**slot** *slot-number*] [**inbound** | **outbound**] **rule-statistics**
Clear the statistics for the QoS policy applied to the control plane.	**reset qos policy control-plane slot** *slot-number*
Clear the statistics for the QoS policy applied in control-plane management view.	**reset qos policy control-plane management**
Clear the statistics for a QoS policy applied globally.	**reset qos** [**ipv6-matching** | **accounting** | **mirroring** | **remarking** | **tcp-erspan** | **exact-matching**] **policy global** [**inbound** | **outbound**]
Clear the statistics about QoS policies applied to Ethernet service instances.	**reset qos** [**ipv6-matching** | **accounting** | **mirroring** | **remarking**] **policy l2vpn-ac** [**interface** *interface-type interface-number* [**service-instance** *instance-id*]] [**inbound**]
Clear the statistics of the QoS policy applied in a certain direction of a VLAN.	**reset qos vlan-policy** [**vlan** *vlan-id*] [**inbound** | **outbound**]

Configuring priority mapping

About priority mapping

When a packet arrives, a device assigns a set of QoS priority parameters to the packet based on either of the following:

- A priority field carried in the packet.
- The port priority of the incoming port.

This process is called priority mapping. During this process, the device can modify the priority of the packet according to the priority mapping rules. The set of QoS priority parameters decides the scheduling priority and forwarding priority of the packet.

Priority mapping is implemented with priority maps and involves the following priorities:

- 802.11e priority.
- 802.1p priority.
- DSCP.
- EXP.
- IP precedence.
- Local precedence.
- Drop priority.

About priorities

Priorities include the following types: priorities carried in packets, and priorities locally assigned for scheduling only.

Packet-carried priorities include 802.1p priority and DSCP precedence. These priorities have global significance and affect the forwarding priority of packets across the network. For more information about these priorities, see "Appendixes."

Locally assigned priorities only have local significance. They are assigned by the device only for scheduling. These priorities include the local precedence, drop priority, and user priority, as follows:

- **Local precedence**—Used for queuing. A local precedence value corresponds to an output queue. A packet with higher local precedence is assigned to a higher priority output queue to be preferentially scheduled.
- **Drop priority**—Used for making packet drop decisions. Packets with the highest drop priority are dropped preferentially.

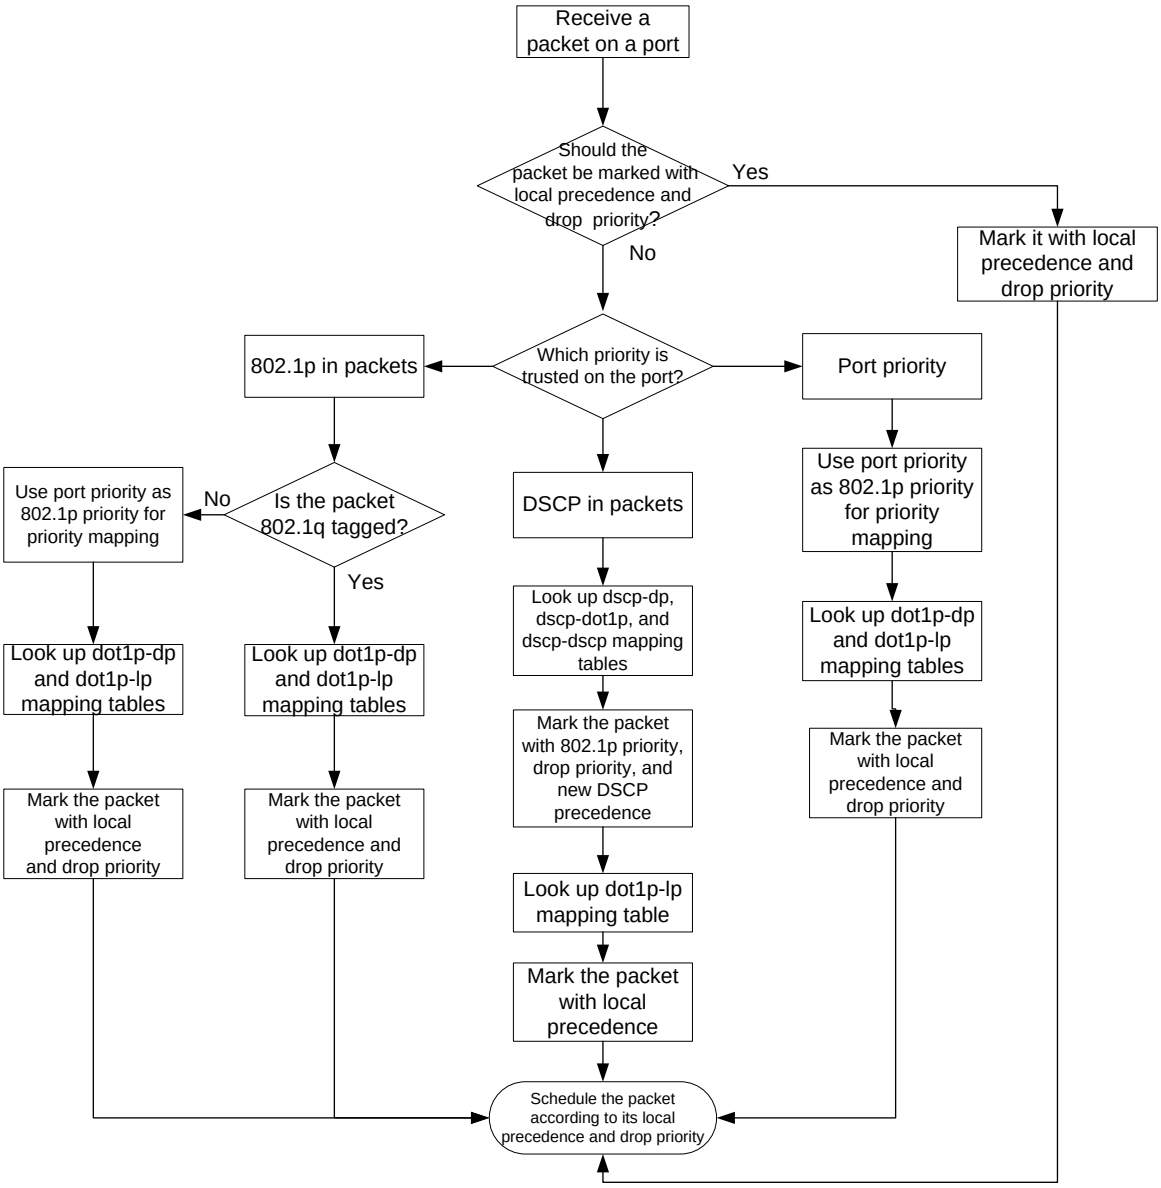
The device supports only local precedence and drop priority for scheduling.

Priority maps

The device provides various types of priority maps. By looking through a priority map, the device decides which priority value to assign to a packet for subsequent packet processing.

The default priority maps (as shown in Appendix B Default priority maps) are available for priority mapping. They are adequate in most cases. If a default priority map cannot meet your requirements, you can modify the priority map as required.

Priority mapping configuration methods



You can configure priority mapping by using any of the following methods:

- **Configuring priority trust mode**—In this method, you can configure a port to look up a trusted priority type (802.1p, for example) in incoming packets in the priority maps. Then, the system maps the trusted priority to the target priority types and values.
- **Changing port priority**—If no packet priority is trusted, the port priority of the incoming port is used. By changing the port priority of a port, you change the priority of the incoming packets on the port.

Priority mapping process

On receiving an Ethernet packet on a port, the switch marks the scheduling priorities (local precedence and drop precedence) for the Ethernet packet. This procedure is done according to the priority trust mode of the receiving port and the 802.1Q tagging status of the packet, as shown in Figure 3.

Figure 3 Priority mapping process for an Ethernet packet

For information about priority marking, see "Configuring priority marking."

Priority mapping tasks at a glance

To configure priority mapping, perform the following tasks:

1. (Optional.) Configuring a priority map
   - Configuring an uncolored priority map
   - Configuring a colored priority map
2. Configure a priority mapping method:
   - Configuring a port to trust packet priority for priority mapping
   - Changing the port priority of an interface

Configuring a priority map

Configuring an uncolored priority map

1. Enter system view.

   system-view

2. Enter priority map view.

   qos map-table { **dot1p-dp** | **dot1p-lp** | **dscp-dp** | **dscp-dscp** | **dscp-lp** | **exp-lp** | **lp-exp** }

3. Configure mappings for the priority map.

   import *import-value-list* **export** *export-value*

   By default, the default priority maps are used. For more information, see "Appendix B Default priority maps."

   If you execute this command multiple times, the most recent configuration takes effect.

Configuring a colored priority map

1. Enter system view.

   system-view

2. Enter colored priority map view.

   qos map-table color { **green** | **yellow** | **red** } **lp-tunnel-dscp**

3. Configure mappings for the colored priority map.

   import *import-value-list* **export** *export-value*

   By default, the default colored priority maps are used. You can use the **display qos map-table color** command to view the default values.

   If you execute this command multiple times, the most recent configuration takes effect.

Configuring a port to trust packet priority for priority mapping

About this task

You can configure the device to trust a particular priority field carried in packets for priority mapping on ports or globally. When you configure the trusted packet priority type on an interface, use the following available keywords:

- **dot1p**—Uses the 802.1p priority of received packets for mapping.
- **dscp**—Uses the DSCP precedence of received IP packets for mapping.

Restrictions and guidelines

For a VXLAN tunnel interface to trust the DSCP priority in the outer IP header of VXLAN packets, you must execute both of the following commands:

- **qos trust tunnel-dscp** (in system view).
- **qos trust dscp** (in interface view for the physical interface of the VXLAN tunnel interface).

The **qos trust tunnel-dscp** command is not supported when the system operating mode is standard. For more information about system operating modes, see device management in *Fundamentals Configuration Guide*.

The term "interface" in this section collectively refers to Layer 2 and Layer 3 Ethernet interfaces. You can use the **port link-mode** command to configure an Ethernet port as a Layer 2 or Layer 3 interface (see *Interface Configuration Guide*).

If you configure both either the following settings and the **qos trust dscp** command on the same interface, only the **qos trust dscp** command takes effect:

- DSCP port priority (**qos priority dscp** *priority-value*).
- DSCP marking action in a QoS policy.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the trusted packet priority type.
   qos trust { **dot1p** | **dscp** }
   By default, an interface does not trust any packet priority.
4. Return to system view.
   quit
5. (Optional.) Configure the global priority trust mode for VXLAN packets.
   qos trust tunnel-dscp
   By default, the global priority trust mode for VXLAN packets is not configured.

Changing the port priority of an interface

About this task

If an interface does not trust any packet priority, the device uses its port priority to look for priority parameters for the incoming packets. By changing port priority, you can prioritize traffic received on different interfaces.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the port priority of the interface.
   qos priority *priority-value*
   The default setting is 0.

Display and maintenance commands for priority mapping

Execute **display** commands in any view.

Task	Command
Display priority map configuration.	**display qos map-table** [**dot1p-dp** | **dot1p-lp** | **dscp-dp** | **dscp-dscp** | **dscp-lp** | **exp-lp** | **lp-exp**]
Display colored priority map configuration.	**display qos map-table color** [**green** | **yellow** | **red**] [**lp-tunnel-dscp**]
Display the trusted packet priority type on a port.	**display qos trust interface** [*interface-type interface-number*]

Priority mapping configuration examples

Example: Configuring a priority trust mode

Network configuration

As shown in Figure 4:

- The 802.1p priority of traffic from Device A to Device C is 3.
- The 802.1p priority of traffic from Device B to Device C is 1.

Configure Device C to preferentially process packets from Device A to the server when GigabitEthernet 1/0/3 of Device C is congested.

Figure 4 Network diagram

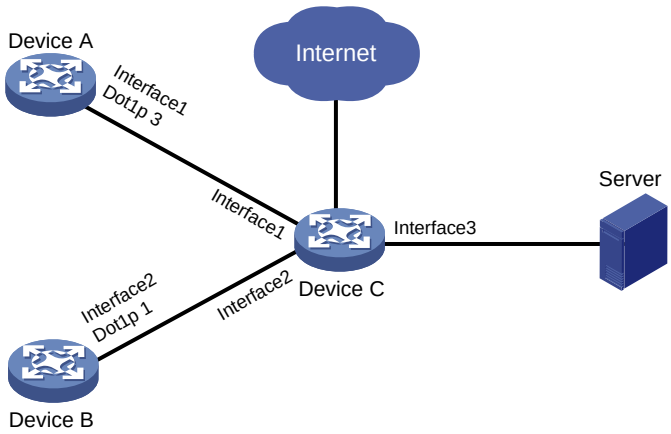


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

(Method 1) Configure Device C to trust packet priority

Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to trust the 802.1p priority for priority mapping.

```
<Sysname> system-view
[Sysname] sysname DeviceC
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] qos trust dot1p
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] qos trust dot1p
[DeviceC-GigabitEthernet1/0/2] quit
```

(Method 2) Configure Device C to trust port priority

Assign port priority to GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2. Make sure the following requirements are met:

- The priority of GigabitEthernet 1/0/1 is higher than that of GigabitEthernet 1/0/2.
- No trusted packet priority type is configured on GigabitEthernet 1/0/1 or GigabitEthernet 1/0/2.

```
<Sysname> system-view
[Sysname] sysname DeviceC
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] qos priority 3
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] qos priority 1
[DeviceC-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Use the **`display qos trust interface`** command to verify that the configuration has been performed successfully.

Configuration files

- Method 1:

```
#
 sysname DeviceC
#
interface GigabitEthernet1/0/1
 port link-mode bridge
 qos trust dot1p
#
interface GigabitEthernet1/0/2
 port link-mode bridge
 qos trust dot1p
#
return
```

- Method 2:

```
#
 sysname DeviceC
#
interface GigabitEthernet1/0/1
 port link-mode bridge
 qos priority 3
#
interface GigabitEthernet1/0/2
```

```
 port link-mode bridge
 qos priority 1
#
return
```

Example: Configuring priority mapping tables and priority marking

Network configuration

As shown in Figure 5:

- The Marketing department connects to GigabitEthernet 1/0/1 of Device, which sets the 802.1p priority of traffic from the Marketing department to 3.
- The R&D department connects to GigabitEthernet 1/0/2 of Device, which sets the 802.1p priority of traffic from the R&D department to 4.
- The Management department connects to GigabitEthernet 1/0/3 of Device, which sets the 802.1p priority of traffic from the Management department to 5.

Configure port priority, 802.1p-to-local mapping table, and priority marking to implement the plan as described in Table 2.

Table 2 Configuration plan

Traffic destination	Traffic priority order	Queuing plan		
		Traffic source	Output queue	Queue priority
Public servers	R&D department > Management department > Marketing department	R&D department	6	High
		Management department	4	Medium
		Marketing department	2	Low
Internet	Management department > Marketing department > R&D department	R&D department	2	Low
		Management department	6	High
		Marketing department	4	Medium

Figure 5 Network diagram

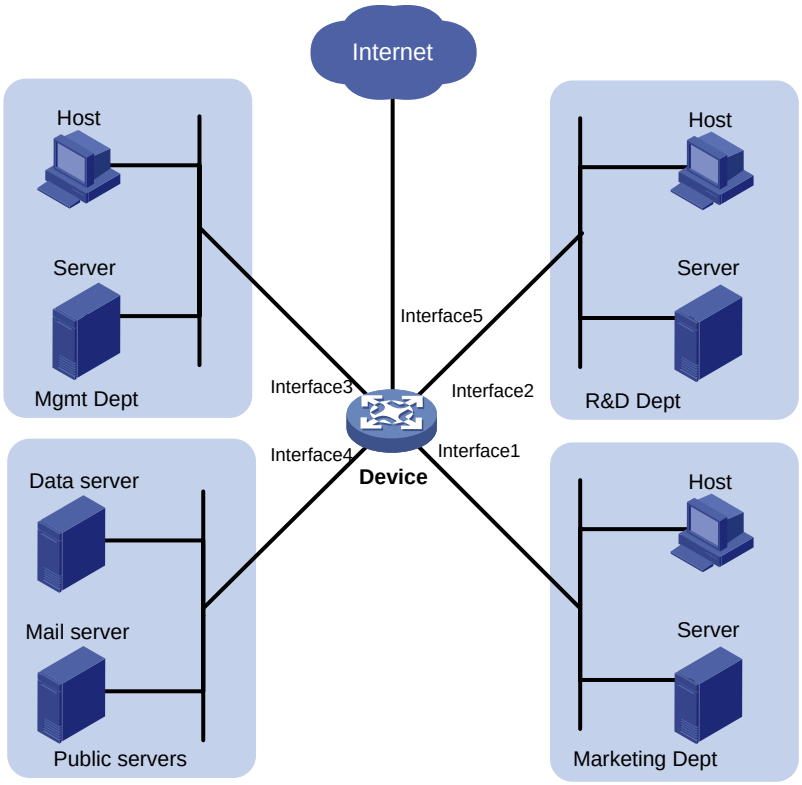

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure trusting port priority:

   # Set the port priority of GigabitEthernet 1/0/1 to 3.

   ```
   <Sysname> system-view
   [Sysname] sysname Device
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] qos priority 3
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Set the port priority of GigabitEthernet 1/0/2 to 4.

   ```
   [Device] interface gigabitethernet 1/0/2
   [Device-GigabitEthernet1/0/2] qos priority 4
   [Device-GigabitEthernet1/0/2] quit
   ```

   # Set the port priority of GigabitEthernet 1/0/3 to 5.

   ```
   [Device] interface gigabitethernet 1/0/3
   [Device-GigabitEthernet1/0/3] qos priority 5
   [Device-GigabitEthernet1/0/3] quit
   ```

2. Configure the 802.1p-to-local mapping table to map 802.1p priority values 3, 4, and 5 to local precedence values 2, 6, and 4.

   This guarantees the R&D department, Management department, and Marketing department decreased priorities to access the public servers.

```
[Device] qos map-table dot1p-lp
[Device-maptbl-dot1p-lp] import 3 export 2
[Device-maptbl-dot1p-lp] import 4 export 6
[Device-maptbl-dot1p-lp] import 5 export 4
[Device-maptbl-dot1p-lp] quit
```

3. Configure priority marking to mark the packets from Management department, Marketing department, and R&D department to the Internet with 802.1p priority values 4, 5, and 3.

   This guarantees the Management department, Marketing department, and R&D department decreased priorities to access the Internet.

   # Create ACL 3000, and configure a rule to match HTTP packets.

```
[Device] acl advanced 3000
[Device-acl-adv-3000] rule permit tcp destination-port eq 80
[Device-acl-adv-3000] quit
```

   # Create a traffic class named **http**, and use ACL 3000 as a match criterion.

```
[Device] traffic classifier http
[Device-classifier-http] if-match acl 3000
[Device-classifier-http] quit
```

   # Create a traffic behavior named **admin**, and configure a marking action for the Management department.

```
[Device] traffic behavior admin
[Device-behavior-admin] remark dot1p 4
[Device-behavior-admin] quit
```

   # Create a QoS policy named **admin**, and associate traffic class **http** with traffic behavior **admin** in QoS policy **admin**.

```
[Device] qos policy admin
[Device-qospolicy-admin] classifier http behavior admin
[Device-qospolicy-admin] quit
```

   # Apply QoS policy **admin** to the inbound direction of GigabitEthernet 1/0/3.

```
[Device] interface gigabitethernet 1/0/3
[Device-GigabitEthernet1/0/3] qos apply policy admin inbound
```

   # Create a traffic behavior named **market**, and configure a marking action for the Marketing department.

```
[Device] traffic behavior market
[Device-behavior-market] remark dot1p 5
[Device-behavior-market] quit
```

   # Create a QoS policy named **market**, and associate traffic class **http** with traffic behavior **market** in QoS policy **market**.

```
[Device] qos policy market
[Device-qospolicy-market] classifier http behavior market
[Device-qospolicy-market] quit
```

   # Apply QoS policy **market** to the inbound direction of GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] qos apply policy market inbound
```

   # Create a traffic behavior named **rd**, and configure a marking action for the R&D department.

```
[Device] traffic behavior rd
```

```
[Device-behavior-rd] remark dot1p 3
[Device-behavior-rd] quit
```

Create a QoS policy named **rd**, and associate traffic class **http** with traffic behavior **rd** in QoS policy **rd**.

```
[Device] qos policy rd
[Device-qospolicy-rd] classifier http behavior rd
[Device-qospolicy-rd] quit
```

Apply QoS policy **rd** to the inbound direction of GigabitEthernet 1/0/2.

```
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] qos apply policy rd inbound
[Device-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Use the **display qos map-table** and **display qos policy interface** commands to verify that the configuration has been performed successfully.

Configuration files

```
#

 rule 0 permit tcp destination-port eq www
#
return
```

Configuring traffic policing, GTS, and rate limit

About traffic policing, GTS, and rate limit

Traffic limit helps assign network resources (including bandwidth) and increase network performance. For example, you can configure a flow to use only the resources committed to it in a certain time range. This avoids network congestion caused by burst traffic.

Traffic policing, Generic Traffic Shaping (GTS), and rate limit control the traffic rate and resource usage according to traffic specifications. You can use token buckets for evaluating traffic specifications.

Traffic evaluation and token buckets

Token bucket features

A token bucket is analogous to a container that holds a certain number of tokens. Each token represents a certain forwarding capacity. The system puts tokens into the bucket at a constant rate. When the token bucket is full, the extra tokens cause the token bucket to overflow.

Evaluating traffic with the token bucket

A token bucket mechanism evaluates traffic by looking at the number of tokens in the bucket. If the number of tokens in the bucket is enough for forwarding the packets:

- The traffic conforms to the specification (called conforming traffic).
- The corresponding tokens are taken away from the bucket.

Otherwise, the traffic does not conform to the specification (called excess traffic).

A token bucket has the following configurable parameters:

- Mean rate at which tokens are put into the bucket, which is the permitted average rate of traffic. It is usually set to the committed information rate (CIR).
- Burst size or the capacity of the token bucket. It is the maximum traffic size permitted in each burst. It is usually set to the committed burst size (CBS). The set burst size must be greater than the maximum packet size.

Each arriving packet is evaluated.

Complicated evaluation

You can set two token buckets, bucket C and bucket E, to evaluate traffic in a more complicated environment and achieve more policing flexibility. The following are main mechanisms used for complicated evaluation:

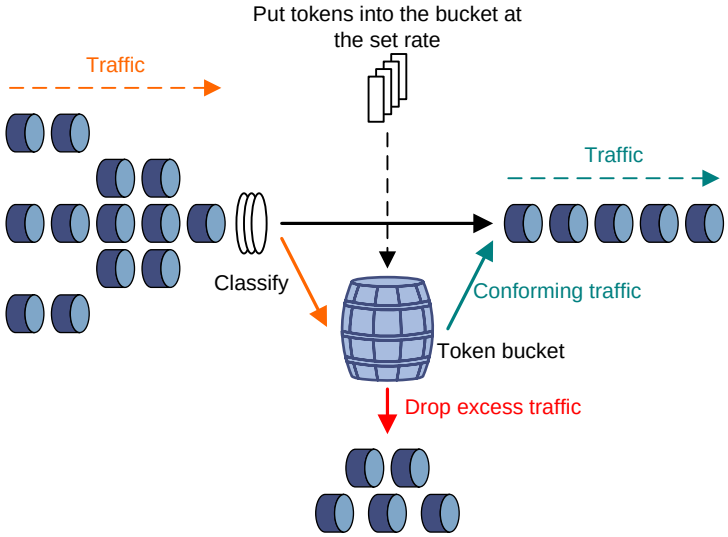
- **Single rate two color**—Uses one token bucket and the following parameters:
  - **CIR**—Rate at which tokens are put into bucket C. It sets the average packet transmission or forwarding rate allowed by bucket C.
  - **CBS**—Size of bucket C, which specifies the transient burst of traffic that bucket C can forward.

  When a packet arrives, the following rules apply:
  - If bucket C has enough tokens to forward the packet, the packet is colored green.
  - Otherwise, the packet is colored red.
- **Single rate three color**—Uses two token buckets and the following parameters:

- **CIR**—Rate at which tokens are put into bucket C. It sets the average packet transmission or forwarding rate allowed by bucket C.
- **CBS**—Size of bucket C, which specifies the transient burst of traffic that bucket C can forward.
- **EBS**—Size of bucket E minus size of bucket C, which specifies the transient burst of traffic that bucket E can forward. The EBS cannot be 0. The size of E bucket is the sum of the CBS and EBS.

When a packet arrives, the following rules apply:

- If bucket C has enough tokens, the packet is colored green.
- If bucket C does not have enough tokens but bucket E has enough tokens, the packet is colored yellow.
- If neither bucket C nor bucket E has sufficient tokens, the packet is colored red.



- **Two rate three color**—Uses two token buckets and the following parameters:
  - **CIR**—Rate at which tokens are put into bucket C. It sets the average packet transmission or forwarding rate allowed by bucket C.
  - **CBS**—Size of bucket C, which specifies the transient burst of traffic that bucket C can forward.
  - **PIR**—Rate at which tokens are put into bucket E, which specifies the average packet transmission or forwarding rate allowed by bucket E.
  - **EBS**—Size of bucket E, which specifies the transient burst of traffic that bucket E can forward.

  When a packet arrives, the following rules apply:
  - If bucket C has enough tokens, the packet is colored green.
  - If bucket C does not have enough tokens but bucket E has enough tokens, the packet is colored yellow.
  - If neither bucket C nor bucket E has sufficient tokens, the packet is colored red.

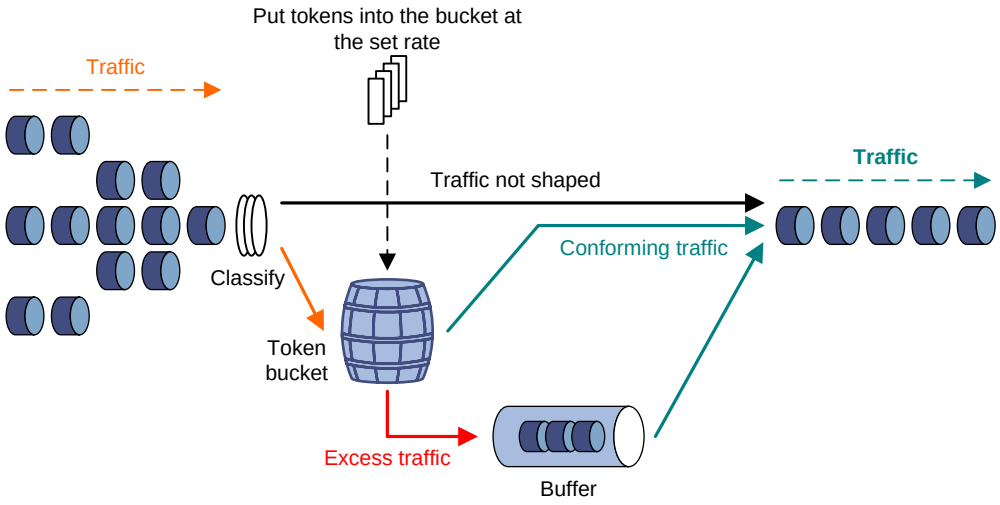
Traffic policing

A typical application of traffic policing is to supervise the specification of traffic entering a network and limit it within a reasonable range. Another application is to "discipline" the extra traffic to prevent aggressive use of network resources by an application. For example, you can limit bandwidth for HTTP packets to less than 50% of the total. If the traffic of a session exceeds the limit, traffic policing can drop the packets or reset the IP precedence of the packets. Figure 6 shows an example of policing outbound traffic on an interface.

Figure 6 Traffic policing

Traffic policing can classify the policed traffic and take predefined policing actions on each packet depending on the evaluation result:

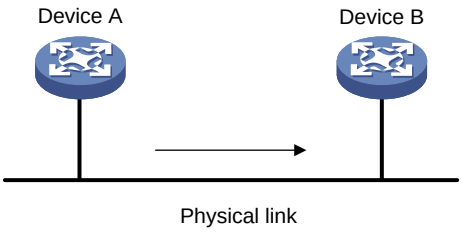
- Forwarding the packet.
- Dropping the packet.
- Forwarding the packet with its precedence re-marked.
- Delivering the packet to next-level traffic policing with its precedence re-marked.



GTS

GTS limits the traffic rate by buffering exceeding traffic. You can use GTS to adapt the traffic output rate on a device to the input traffic rate of its connected device to avoid packet loss.

The differences between traffic policing and GTS are as follows:

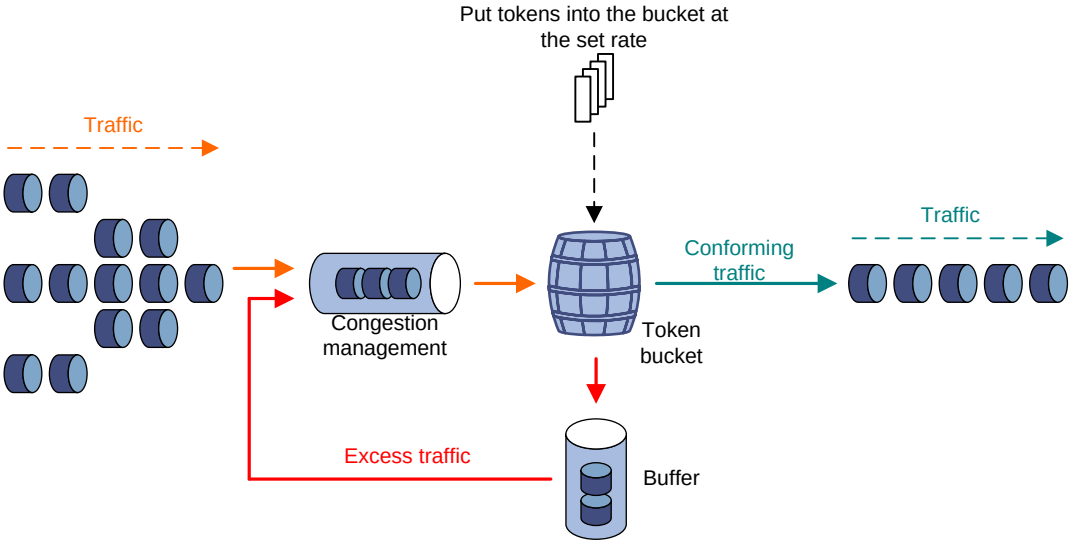


- Packets to be dropped with traffic policing are retained in a buffer or queue with GTS, as shown in Figure 7. When enough tokens are in the token bucket, the buffered packets are sent at an even rate.
- GTS can result in additional delay and traffic policing does not.

Figure 7 GTS

For example, in Figure 8, Device B performs traffic policing on packets from Device A and drops packets exceeding the limit. To avoid packet loss, you can perform GTS on the outgoing interface of Device A so that packets exceeding the limit are cached in Device A. Once resources are released, GTS takes out the cached packets and sends them out.

Figure 8 GTS application



Rate limit

The rate limit of an interface or PW specifies the maximum rate for forwarding packets (excluding critical packets).

Rate limit also uses token buckets for traffic control. When rate limit is configured on an interface, a token bucket handles all packets to be sent through the interface for rate limiting. If enough tokens are in the token bucket, packets can be forwarded. Otherwise, packets are put into QoS queues for congestion management. In this way, the traffic passing the interface is controlled.

Figure 9 Rate limit implementation

The token bucket mechanism limits traffic rate when accommodating bursts. It allows bursty traffic to be transmitted if enough tokens are available. If tokens are scarce, packets cannot be transmitted until efficient tokens are generated in the token bucket. It restricts the traffic rate to the rate for generating tokens.

Rate limit controls the total rate of all packets on an interface. It is easier to use than traffic policing in controlling the total traffic rate.

Restrictions and guidelines: Traffic policing, GTS, and rate limit configuration

The specified CIR does not take traffic transmitted in interframe gaps into account, and the actually allowed rate on an interface is greater than the specified CIR.

An interframe gap is a time interval for transmitting 12 bits between frames. This gap serves the following roles:

- Allows the device to differentiate one frame from another.
- Allows for time for the device to process the current frame and to prepare for receiving the next frame.

Configuring traffic policing

Configuring traffic policing by using the MQC approach

Restrictions and guidelines

A traffic policing action takes effect only when a QoS policy is applied to the following application destinations:

- Interface.
- VLANs.
- Globally.

Procedure

1. Enter system view.
   system-view
2. Define a traffic class.
   a. Create a traffic class and enter traffic class view.
      traffic classifier *classifier-name* [**operator** { **and** | **or** }]
   b. Configure a match criterion.
      if-match *match-criteria*
      By default, no match criterion is configured.
      For more information about the **if-match** command, see *ACL and QoS Command Reference*.
   c. Return to system view.
      quit
3. Define a traffic behavior.
   a. Create a traffic behavior and enter traffic behavior view.
      traffic behavior *behavior-name*
   b. Configure a traffic policing action.
      car cir *committed-information-rate* [**cbs** *committed-burst-size* [**ebs** *excess-burst-size*]][**green** *action* | **red** *action* | **yellow** *action*] *
      car cir *committed-information-rate* [**cbs** *committed-burst-size*] **pir** *peak-information-rate* [**ebs** *excess-burst-size*] [**green** *action* | **red** *action* | **yellow** *action*] *
      By default, no traffic policing action is configured.
   c. Return to system view.
      quit
4. Define a QoS policy.
   a. Create a QoS policy and enter QoS policy view.
      qos policy *policy-name*
   b. Associate the traffic class with the traffic behavior in the QoS policy.
      classifier *classifier-name* **behavior** *behavior-name*
      By default, a traffic class is not associated with a traffic behavior.
   c. Return to system view.
      quit
5. Apply the QoS policy.
   For more information, see "Applying the QoS policy."
   By default, no QoS policy is applied.

Configuring GTS

Configuring queue-based GTS

Restrictions and guidelines

A queue-based GTS action takes effect only on outgoing traffic in the specified queue.

The term "interface" in this section collectively refers to Layer 2 and Layer 3 Ethernet interfaces. You can use the **port link-mode** command to configure an Ethernet port as a Layer 2 or Layer 3 interface (see *Interface Configuration Guide*).

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure GTS for a queue.
   qos gts queue *queue-id* **cir** *committed-information-rate* [**cbs** *committed-burst-size*]
   By default, GTS is not configured on an interface queue.

Configuring the rate limit

Configuring the rate limit for an interface

Restrictions and guidelines

The term "interface" in this section collectively refers to Layer 2 and Layer 3 Ethernet interfaces. You can use the **port link-mode** command to configure an Ethernet port as a Layer 2 or Layer 3 interface (see *Layer 2—LAN Switching Configuration Guide*).

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the rate limit for the interface.
   qos lr { **inbound** | **outbound** } **cir** *committed-information-rate* [**cbs** *committed-burst-size*]
   By default, no rate limit is configured on an interface.

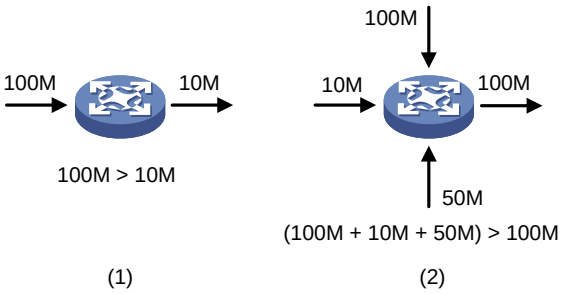
Display and maintenance commands for traffic policing, GTS, and rate limit

Execute **display** commands in any view.

Task	Command
Display ACL rules in the ACL whitelist.	**display acl whitelist** [**ipv6**] **slot** *slot-number*
Display GTS configuration and statistics for interfaces.	**display qos gts interface** [*interface-type interface-number*]
Display rate limit configuration and statistics.	**display qos lr interface** [*interface-type*

	interface-number]
Display QoS and ACL resource usage.	**display qos-acl resource** [**slot** *slot-number*]
Display traffic behavior configuration.	**display traffic behavior user-defined** [*behavior-name*]

Configuring congestion management



About congestion management

Cause, negative results, and countermeasure of congestion

Congestion occurs on a link or node when traffic size exceeds the processing capability of the link or node. It is typical of a statistical multiplexing network and can be caused by link failures, insufficient resources, and various other causes.

Figure 10 shows two typical congestion scenarios.

Figure 10 Traffic congestion scenarios

Congestion produces the following negative results:

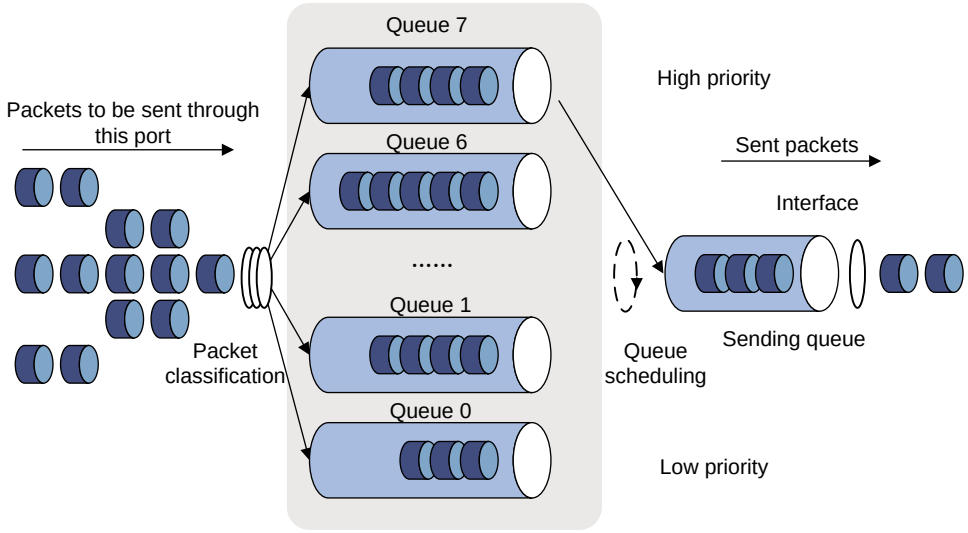
- Increased delay and jitter during packet transmission.
- Decreased network throughput and resource use efficiency.
- Network resource (memory, in particular) exhaustion and even system breakdown.

Congestion is unavoidable in switched networks and multiuser application environments. To improve the service performance of your network, take measures to manage and control it.

The key to congestion management is defining a resource dispatching policy to prioritize packets for forwarding when congestion occurs.

Congestion management methods

Congestion management uses queuing and scheduling algorithms to classify and sort traffic leaving a port.



The device supports the following queuing mechanisms:

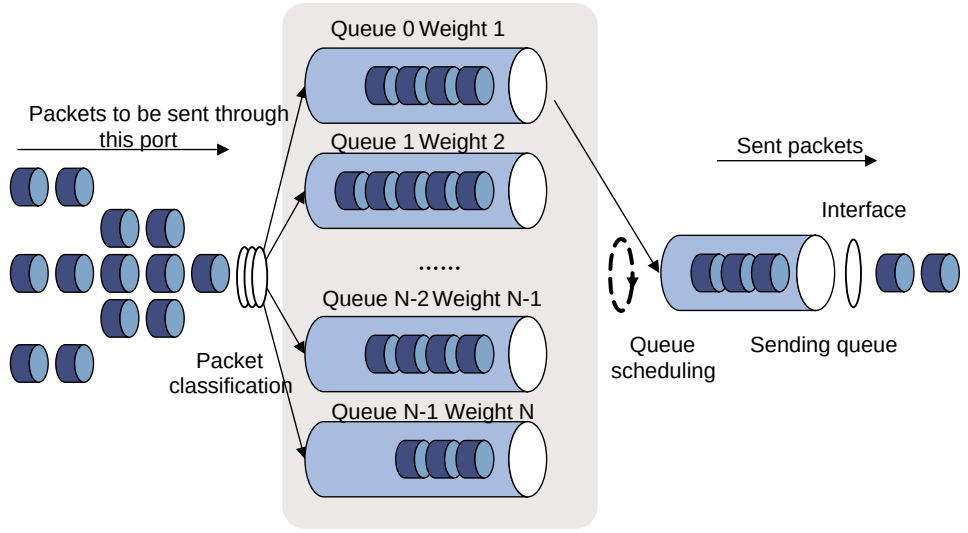
- SP.
- WRR.
- WFQ.
- CBQ.

SP queuing

SP queuing is designed for mission-critical applications that require preferential service to reduce the response delay when congestion occurs.

Figure 11 SP queuing

In Figure 11, SP queuing classifies eight queues on a port into eight classes, numbered 7 to 0 in descending priority order.



SP queuing schedules the eight queues in the descending order of priority. SP queuing sends packets in the queue with the highest priority first. When the queue with the highest priority is empty, it sends packets in the queue with the second highest priority, and so on. You can assign mission-critical packets to a high priority queue to make sure they are always served first. Common service packets can be assigned to low priority queues to be transmitted when high priority queues are empty.

The disadvantage of SP queuing is that packets in the lower priority queues cannot be transmitted if packets exist in the higher priority queues. In the worst case, lower priority traffic might never get serviced.

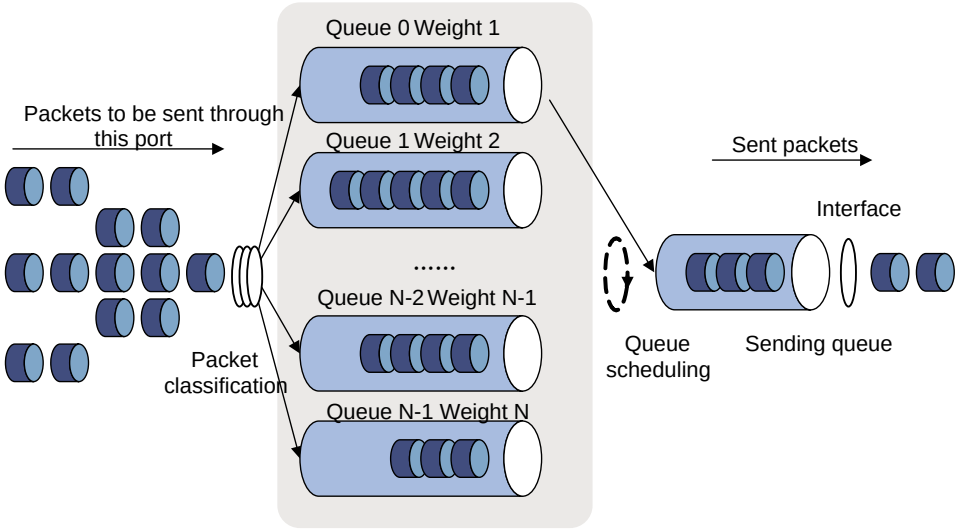
WRR queuing

WRR queuing schedules all the queues in turn to ensure that every queue is served for a certain time, as shown in Figure 12.

Figure 12 WRR queuing

Assume a port provides eight output queues. WRR assigns each queue a weight value (represented by w7, w6, w5, w4, w3, w2, w1, or w0). The weight value of a queue decides the proportion of resources assigned to the queue. On a 100 Mbps port, you can set the weight values to 50, 30, 10, 10, 50, 30, 10, and 10 for w7 through w0. In this way, the queue with the lowest priority can get a minimum of 5 Mbps of bandwidth. WRR solves the problem that SP queuing might fail to serve packets in low-priority queues for a long time.

Another advantage of WRR queuing is that when the queues are scheduled in turn, the service time for each queue is not fixed. If a queue is empty, the next queue will be scheduled immediately. This improves bandwidth resource use efficiency.



WRR queuing includes the following types:

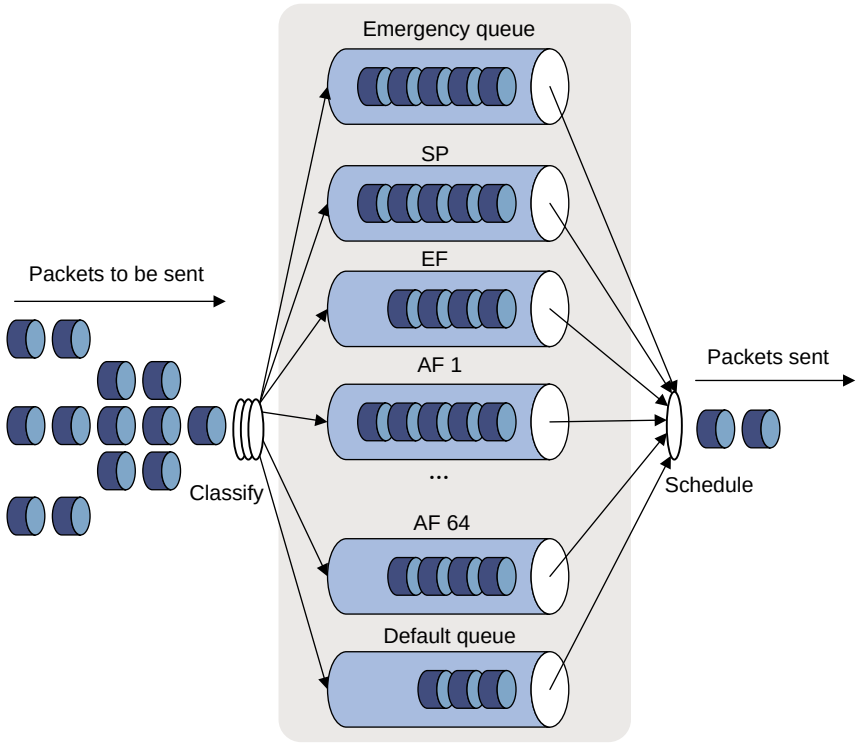
- **Basic WRR queuing**—Contains multiple queues. You can set the weight for each queue, and WRR schedules these queues based on the user-defined parameters in a round robin manner.
- **Group-based WRR queuing**—All the queues are scheduled by WRR. You can divide output queues to WRR priority queue group 1 and WRR priority queue group 2. Round robin queue scheduling is performed for group 1 first. If group 1 is empty, round robin queue scheduling is performed for group 2.

On an interface enabled with group-based WRR queuing, you can assign queues to the SP group. Queues in the SP group are scheduled with SP. The SP group has higher scheduling priority than the WRR groups.

WFQ queuing

Figure 13 WFQ queuing

WFQ is similar to WRR. WFQ queuing includes basic WFQ queuing and group-based WFQ queuing.



On an interface with group-based WFQ queuing enabled, you can also assign queues to the SP group. The difference is that WFQ enables you to set guaranteed bandwidth that a WFQ queue can get during congestion.

SP+WFQ queuing schedules traffic in the following order:

1. Schedules the traffic conforming to the minimum guaranteed bandwidth of each queue in the WFQ group.
2. Schedules the queues in the SP group based on their priorities.
3. Schedules the traffic in each queue in the WFQ group according to the configured weights when all queues in the SP group are empty.

CBQ

Figure 14 CBQ

Class-based queuing (CBQ) extends WFQ by supporting user-defined classes. When network congestion occurs, CBQ uses user-defined traffic match criteria to enqueue packets. Before packets are enqueued, congestion avoidance actions, such as tail drop or WRED and bandwidth restriction check, are performed. When being dequeued, packets are scheduled by WFQ.

CBQ provides the following queues:

- **Emergency queue**—Enqueues emergent packets. The emergency queue is a FIFO queue without bandwidth restriction.
- **Strict priority (SP) queuing**—SP queuing is designed for mission-critical applications. Mission-critical applications require preferential treatment to reduce the response delay when congestion occurs. With SP queuing, CBQ can provide strict priority service. A maximum of 64 SP queues are supported.
- **Low Latency Queuing (LLQ)**—An EF queue. Because packets are fairly treated in CBQ, delay-sensitive flows like video and voice packets might not be transmitted timely. To solve this problem, LLQ combines PQ and CBQ to preferentially transmit delay-sensitive flows like voice packets. When defining traffic classes for LLQ, you can configure a class of packets to be preferentially transmitted. The packets of all priority classes are assigned to the same priority queue. Bandwidth restriction on each class of packets is checked before the packets are enqueued. During the dequeuing operation, packets in the priority queue are transmitted first. To reduce the delay of the other queues except the priority queue, LLQ assigns the maximum available bandwidth to each priority class. The bandwidth value polices traffic during congestion. When no congestion is present, a priority class can use more than the bandwidth assigned to it. During congestion, the packets of each priority class exceeding the assigned bandwidth are discarded.
- **Bandwidth queuing (BQ)**—An AF queue. The BQ provides guaranteed bandwidth for AF traffic, and schedules the AF classes proportionally. The system supports up to 64 AF queues.
- **Default queue**—A WFQ queue. The default queue transmits the BE traffic by using the remaining interface bandwidth.

The system matches packets with classification rules in the following order:

- Match packets with priority classes and then the other classes.
- Match packets with priority classes in the configuration order.
- Match packets with other classes in the configuration order.
- Match packets with classification rules in a class in the configuration order.

congestion management tasks at a glance

To configure congestion management, perform the following tasks:

1.
2. Configuring queuing on an interface
   - Configuring SP queuing
   - Configuring WRR queuing
   - Configuring WFQ queuing
   - Configuring SP+WRR queuing
   - Configuring SP+WFQ queuing
3. Configuring a queue scheduling profile

Configuring queuing on an interface

Restrictions and guidelines for queuing configuration

The term "interface" in this section collectively refers to Layer 2 and Layer 3 Ethernet interfaces. You can use the **port link-mode** command to configure an Ethernet port as a Layer 2 or Layer 3 interface (see *Layer 2—LAN Switching Configuration Guide*).

Configuring SP queuing

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure SP queuing.
   qos sp
   By default, an interface uses SP queuing.

Configuring WRR queuing

Configuring group-based WRR queuing

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable WRR queuing.

qos wrr { **byte-count** | **weight** }

By default, an interface uses SP queuing.

4. Assign a queue to a WRR group, and configure scheduling parameters for the queue.

qos wrr *queue-id* **group** { **1** | **2** } { **byte-count** | **weight** } *schedule-value*

By default, all queues on a WRR-enabled interface are in WRR group 1, and queues 0 through 7 have a weight of 1, 2, 3, 4, 5, 9, 13, and 15, respectively.

Configuring WFQ queuing

Configuring grouped WFQ queues

1. Enter system view.

system-view

2. Enter interface view.

interface *interface-type interface-number*

3. Enable WFQ queuing.

qos wfq { **byte-count** | **weight** }

By default, an interface uses SP queuing.

4. Assign a queue to a WFQ group, and configure scheduling parameters for the queue.

qos wfq *queue-id* **group** { **1** | **2** } { **byte-count** | **weight** } *schedule-value*

By default, all queues on a WFQ-enabled interface are in WFQ group 1 and have a weight of 1.

Configuring SP+WRR queuing

Restrictions and guidelines

To configure the scheduling weight, you must specify the same scheduling unit as specified when enabling WRR queuing.

Procedure

1. Enter system view.

system-view

2. Enter interface view.

interface *interface-type interface-number*

3. Enable byte-count or packet-count WRR queuing.

qos wrr { **byte-count** | **weight** }

By default, an interface uses SP queuing.

4. Assign a queue to the SP group.

qos wrr *queue-id* **group sp**

By default, all queues on a WRR-enabled interface are in WRR group 1.

5. Assign a queue to a WRR group, and configure a scheduling weight for the queue.

qos wrr *queue-id* **group** { **1** | **2** } { **byte-count** | **weight** } *schedule-value*

By default, all queues on a WRR-enabled interface are in WRR group 1, and queues 0 through 7 have a weight of 1, 2, 3, 4, 5, 9, 13, and 15, respectively.

Configuring SP+WFQ queuing

Restrictions and guidelines

To configure the scheduling weight, you must specify the same scheduling unit as specified when enabling WFQ queuing.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable byte-count or packet-count WFQ queuing.
   qos wfq { **byte-count** | **weight** }
   By default, an interface uses SP queuing.
4. Assign a queue to the SP group.
   qos wfq *queue-id* **group sp**
   By default, all queues on a WFQ-enabled interface are in WFQ group 1.
5. Assign a queue to a WFQ queue scheduling group, and configure a scheduling weight for the queue.
   qos wfq *queue-id* **group** { **1** | **2** } { **byte-count** | **weight** } *schedule-value*
   By default, all queues on a WFQ-enabled interface are in WFQ group 1 and have a weight of 1.
6. (Optional.) Set the minimum guaranteed bandwidth for a queue.
   qos bandwidth queue *queue-id* **min** *bandwidth-value*
   By default, the minimum guaranteed bandwidth for a WFQ queue in an WFQ group is not set.

Configuring CBQ

Restrictions and guidelines for CBQ configuration

When you configure CBQ, follow these restrictions and guidelines:

- Only one of the following queuing actions can be configured in the same behavior:
  - AF.
  - EF.
  - SP.
  - WFQ.
- To configure **queue af** for multiple classes of a policy, you must configure them in one of the following units:
  - Bandwidth in kbps.
  - Percentage of the available bandwidth.
  - Percentage of the remaining bandwidth.
- In a QoS policy, if AF is configured in percentage of the remaining bandwidth, EF can be configured in absolute value or in percentage.
- In a QoS policy, if AF is configured in absolute value or in percentage, EF can be configured in absolute value or in percentage.

- You must configure the rate limit on the main interface for the CBQ feature to take effect on a subinterface.
- The default class cannot be associated with a traffic behavior including EF or SP.
- You can associate the traffic behavior that contains a WFQ action only with the default class.
- RTPQ and CBQ are mutually exclusive. CBQ can use LLQ to provide priority service for real-time traffic.
-

Configure AF and the minimum guaranteed bandwidth

Restrictions and guidelines

- The **undo queue af** command also cancels the **queue-length** command configuration and all WRED-related settings.
- The **wred** and **queue-length** commands are mutually exclusive in a traffic behavior.
- The **undo wred** [**dscp** | **ip-precedence**] command also cancels all other WRED-related settings.
- A QoS policy that contains an AF action can be applied to the outbound direction of an interface or the inbound direction for a user profile. To modify a QoS policy applied to a user profile, follow these steps:
  a. Remove the QoS policy from the user profile.
  b. Configure a new QoS policy.
  c. Apply the new QoS policy to the user profile.

Procedure

1. Enter system view.
   system-view
2. Define a traffic class.
   a. Create a traffic class and enter traffic class view.
   traffic classifier *classifier-name* [**operator** { **and** | **or** }]
   b. Configure a match criterion.
   if-match [**not**] *match-criteria*
   By default, no match criterion is configured.
   For more information about configuring match criteria, see *ACL and QoS Command Reference*.
   c. Return to system view.
   quit
3. Define a traffic behavior.
   a. Create a traffic behavior and enter traffic behavior view.
   traffic behavior *behavior-name*
   b. Configure AF and the minimum guaranteed bandwidth.
   queue af bandwidth { *bandwidth* [**pir** *peak-information-rate*] | **pct** *percentage* | **remaining-pct** *remaining-percentage* }
   By default, AF is not configured.
   c. (Optional.) Set a weight for the AF queue.
   weight *weight-value*
   The default setting is 1.

d. (Optional.) Set the maximum queue size.

queue-length *queue-length*

The default for this command varies by device model.

If the burst traffic is too heavy, increase the queue length to make queue scheduling more accurate.

e. Enable WRED.

wred [**dscp** | **ip-precedence**]

By default, WRED is not enabled.

f. Set the exponent for WRED to calculate the average queue size.

wred weighting-constant *exponent*

The default setting is 9.

g. Set the lower limit, upper limit, and drop probability denominator for a DSCP value in WRED

wred dscp *dscp-value* **low-limit** *low-limit* **high-limit** *high-limit* [**discard-probability** *discard-prob*]

By default, the lower limit is 10, the upper limit is 30, and the drop probability denominator is 10.

You must enable DSCP-based WRED by using the **wred dscp** command before you configure this command.

h. Set the lower limit, upper limit, and drop probability denominator for an IP precedence in WRED.

wred ip-precedence *precedence* **low-limit** *low-limit* **high-limit** *high-limit* [**discard-probability** *discard-prob*]

By default, the lower limit is 10, the upper limit is 30, and the drop probability denominator is 10.

i. Return to system view.

quit

4. Define a QoS policy.

a. Create a QoS policy and enter QoS policy view.

qos policy *policy-name*

b. Associate a traffic behavior with a class in the policy.

classifier *classifier-name* **behavior** *behavior-name*

By default, a class is not associated with a behavior.

c. Return to system view.

quit

5. Apply the QoS policy.

For more information, see "Applying the QoS policy."

By default, no QoS policy is applied.

Configuring EF and the maximum bandwidth

Restrictions and guidelines

A QoS policy that contains an EF action can be applied to the outbound direction of an interface or the inbound direction for a user profile. To modify a QoS policy applied to a user profile, follow these steps:

1. Remove the QoS policy from the user profile.

2. Configure a new QoS policy.

3. Apply the new QoS policy to the user profile.

Procedure

1. Enter system view.

   system-view
2. Define a traffic class.
   a. Create a traffic class and enter traffic class view.

      traffic classifier *classifier-name* [**operator** { **and** | **or** }]
   b. Configure a match criterion.

      if-match [**not**] *match-criteria*

      By default, no match criterion is configured.

      For more information about configuring match criteria, see *ACL and QoS Command Reference*.
   c. Return to system view.

      quit
3. Define a traffic behavior.
   a. Create a traffic behavior and enter traffic behavior view.

      traffic behavior *behavior-name*
   b. Configure EF and the maximum bandwidth.

      queue ef bandwidth { *bandwidth* [**cbs** *burst*] [**pir** *peak-information-rate*] | **pct** *percentage* [**cbs-ratio** *ratio*] }

      By default, EF is not configured.
   c. (Optional.) Set a weight for the EF queue.

      weight *weight-value*

      The default setting is 1.
   d. Return to system view.

      quit
4. Define a QoS policy.
   a. Create a QoS policy and enter QoS policy view.

      qos policy *policy-name*
   b. Associate a traffic behavior with a class in the policy.

      classifier *classifier-name* **behavior** *behavior-name*

      By default, a class is not associated with a behavior.
   c. Return to system view.

      quit
5. Apply the QoS policy.

   For more information, see "Applying the QoS policy."

   By default, no QoS policy is applied.

Configuring SP

Restrictions and guidelines

A QoS policy that contains an SP action can be applied to the outbound direction of an interface or the inbound direction for a user profile. To modify a QoS policy applied to a user profile, follow these steps:

1. Remove the QoS policy from the user profile.
2. Configure a new QoS policy.
3. Apply the new QoS policy to the user profile.

Procedure

1. Enter system view.
   system-view
2. Define a traffic class.
   a. Create a traffic class and enter traffic class view.
      traffic classifier *classifier-name* [**operator** { **and** | **or** }]
   b. Configure a match criterion.
      if-match [**not**] *match-criteria*
      By default, no match criterion is configured.
      For more information about configuring match criteria, see *ACL and QoS Command Reference*.
   c. Return to system view.
      quit
3. Define a traffic behavior.
   a. Create a traffic behavior and enter traffic behavior view.
      traffic behavior *behavior-name*
   b. Configure SP.
      queue sp
      By default, SP is not configured.
   c. Return to system view.
      quit
4. Define a QoS policy.
   a. Create a QoS policy and enter QoS policy view.
      qos policy *policy-name*
   b. Associate a traffic behavior with a class in the policy.
      classifier *classifier-name* **behavior** *behavior-name*
      By default, a class is not associated with a behavior.
   c. Return to system view.
      quit
5. Apply the QoS policy.
   For more information, see "Applying the QoS policy."
   By default, no QoS policy is applied.

Configuring WFQ

Restrictions and guidelines

- The **undo queue wfq** command also cancels the **queue-length** command configuration and all WRED-related settings.
- The **wred** and **queue-length** commands are mutually exclusive in a traffic behavior.
- The **undo wred** [**dscp** | **ip-precedence**] command also cancels all other WRED-related settings.

- A QoS policy that contains a WFQ action can be applied to the outbound direction of an interface or the inbound direction for a user profile. To modify a QoS policy applied to a user profile, follow these steps:
  a. Remove the QoS policy from the user profile.
  b. Configure a new QoS policy.
  c. Apply the new QoS policy to the user profile.

Procedure

1. Enter system view.
system-view

2. Define a traffic class.
a. Create a traffic class and enter traffic class view.
traffic classifier *classifier-name* [**operator** { **and** | **or** }]
b. Configure a match criterion.
if-match [**not**] *match-criteria*
By default, no match criterion is configured.
For more information about configuring match criteria, see *ACL and QoS Command Reference*.
c. Return to system view.
quit

3. Define a traffic behavior.
a. Create a traffic behavior and enter traffic behavior view.
traffic behavior *behavior-name*
b. Configure WFQ.
queue wfq [**queue-number** *total-queue-number*]
By default, WFQ is not configured.
c. (Optional.) Set a weight for the WFQ queue.
weight *weight-value*
The default setting is 1.
d. Set the maximum queue size.
queue-length *queue-length*
The default for this command varies by device model.
If the burst traffic is too heavy, increase the queue length to make queue scheduling more accurate.
e. Enable WRED.
wred [**dscp** | **ip-precedence**]
By default, WRED is not enabled.
f. Set the exponent for WRED to calculate the average queue size
wred weighting-constant *exponent*
The default setting is 9.
g. Set the lower limit, upper limit, and drop probability denominator for a DSCP value in WRED
wred dscp *dscp-value* **low-limit** *low-limit* **high-limit** *high-limit* [**discard-probability** *discard-prob*]
By default, the lower limit is 10, the upper limit is 30, and the drop probability denominator is 10.

h. Set the lower limit, upper limit, and drop probability denominator for an IP precedence in WRED.

wred ip-precedence *precedence* **low-limit** *low-limit* **high-limit** *high-limit* [**discard-probability** *discard-prob*]

By default, the lower limit is 10, the upper limit is 30, and the drop probability denominator is 10.

i. Return to system view.

quit

4. Define a QoS policy.

a. Create a QoS policy and enter QoS policy view.

qos policy *policy-name*

b. Associate a traffic behavior with a class in the policy.

classifier *classifier-name* **behavior** *behavior-name*

By default, a class is not associated with a behavior.

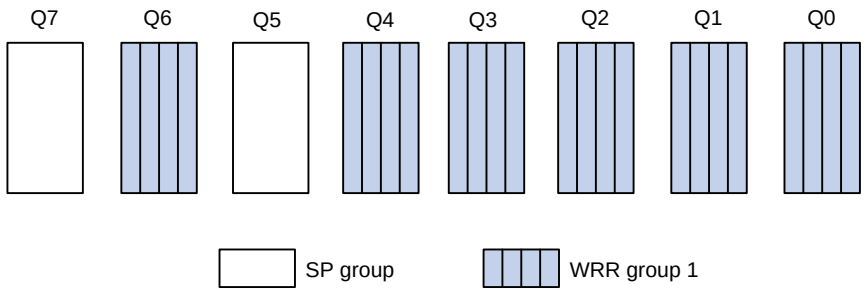
c. Return to system view.

quit

5. Apply the QoS policy.

For more information, see "Applying the QoS policy."

By default, no QoS policy is applied.



Configuring a queue scheduling profile

About queue scheduling profiles

In a queue scheduling profile, you can configure scheduling parameters for each queue. By applying the queue scheduling profile to an interface or session group profile, you can implement congestion management on the interface or session group profile.

Queue scheduling profiles support three queue scheduling algorithms: SP, WRR, and WFQ. In a queue scheduling profile, you can configure SP + WRR or SP + WFQ. For information about each scheduling algorithm, see "About congestion management." When SP and WRR groups are configured in a queue scheduling profile, Figure 15 shows the scheduling order.

Figure 15 Queue scheduling profile configured with both SP and WRR

- Queue 7 has the highest priority in the SP group. Its packets are sent preferentially.
- Queue 5 has the second highest priority in the SP group. Packets in queue 5 are sent when queue 7 is empty.
- All queues in WRR group 1 are scheduled according to their weights. When queue 7 and queue 5 are empty, WRR group 1 is scheduled.

Restrictions and guidelines for queue scheduling profile configuration

When you configure a queue scheduling profile, follow these restrictions and guidelines:

- The term "interface" in this section collectively refers to Layer 2 and Layer 3 Ethernet interfaces. You can use the **port link-mode** command to configure an Ethernet port as a Layer 2 or Layer 3 interface (see *Layer 2—LAN Switching Configuration Guide*).
- Only one queue scheduling profile can be applied to an interface or session group profile.
- You can modify the scheduling parameters in a queue scheduling profile already applied to an interface, the switching fabric module, or a session group profile.

Configuring a queue scheduling profile

1. Enter system view.

   system-view
2. Create a queue scheduling profile and enter queue scheduling profile view.

   qos qmprofile *profile-name*
3. (Optional.) Configure queue scheduling parameters.
   - Configure a queue to use SP.

     queue *queue-id* **sp**
   - Configure a queue to use WRR.

     queue *queue-id* **wrr group** *group-id* { **weight** | **byte-count** } *schedule-value*
   - Configure a queue to use WFQ.

     queue *queue-id* **wfq group** *group-id* { **weight** | **byte-count** } *schedule-value*

   By default, all queues in a queue scheduling profile are SP queues.
4. (Optional.) Set the minimum guaranteed bandwidth for a WFQ queue.

   bandwidth queue *queue-id* **min** *bandwidth-value*

   By default, the minimum guaranteed bandwidth is not set for a WFQ queue.

Applying a queue scheduling profile

1. Enter system view.

   system-view
2. Execute the following commands in sequence to apply the queue scheduling profile to the outbound direction of an interface:

   interface *interface-type interface-number*

   qos apply qmprofile *profile-name*

   By default, no queue scheduling profile is applied to an interface.

Example: Configuring a queue scheduling profile

Network configuration

Configure a queue scheduling profile to meet the following requirements on GigabitEthernet 1/0/1:

- Queue 7 has the highest priority, and its packets are sent preferentially.
- Queue 0 through queue 6 are in the WRR group and are scheduled according to their packet-count weights, which are 2, 1, 2, 4, 6, 8, and 10, respectively. When queue 7 is empty, the WRR group is scheduled.

Procedure

Enter system view.

```
<Sysname> system-view
```

Create a queue scheduling profile named **qm1**.

```
[Sysname] qos qmprofile qm1
[Sysname-qmprofile-qm1]
```

Configure queue 7 to use SP queuing.

```
[Sysname-qmprofile-qm1] queue 7 sp
```

Assign queue 0 through queue 6 to WRR group 1, with their packet-count weights as 2, 1, 2, 4, 6, 8, and 10, respectively.

```
[Sysname-qmprofile-qm1] queue 0 wrr group 1 weight 2
[Sysname-qmprofile-qm1] queue 1 wrr group 1 weight 1
[Sysname-qmprofile-qm1] queue 2 wrr group 1 weight 2
[Sysname-qmprofile-qm1] queue 3 wrr group 1 weight 4
[Sysname-qmprofile-qm1] queue 4 wrr group 1 weight 6
[Sysname-qmprofile-qm1] queue 5 wrr group 1 weight 8
[Sysname-qmprofile-qm1] queue 6 wrr group 1 weight 10
[Sysname-qmprofile-qm1] quit
```

Apply queue scheduling profile **qm1** to GigabitEthernet 1/0/1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos apply qmprofile qm1
```

After the configuration is completed, GigabitEthernet 1/0/1 performs queue scheduling as specified in queue scheduling profile **qm1**.

Display and maintenance commands for congestion management

Execute **display** commands in any view.

Task	Command

Display SP queuing configuration.	**display qos queue sp interface** [*interface-type interface-number*]
Display WFQ queuing configuration.	**display qos queue wfq interface** [*interface-type*

Task	Command
	interface-number]
Display WRR queuing configuration.	**display qos queue wrr interface** [*interface-type interface-number*]

Configuring congestion avoidance

About congestion avoidance

Avoiding congestion before it occurs is a proactive approach to improving network performance. As a flow control mechanism, congestion avoidance:

- Actively monitors network resources (such as queues and memory buffers).
- Drops packets when congestion is expected to occur or deteriorate.

When dropping packets from a source end, congestion avoidance cooperates with the flow control mechanism at the source end to regulate the network traffic size. The combination of the local packet drop policy and the source-end flow control mechanism implements the following functions:

- Maximizes throughput and network use efficiency.
- Minimizes packet loss and delay.

Tail drop

Congestion management techniques drop all packets that are arriving at a full queue. This tail drop mechanism results in global TCP synchronization. If packets from multiple TCP connections are dropped, these TCP connections go into the state of congestion avoidance and slow start to reduce traffic. However, traffic peak occurs later. Consequently, the network traffic jitters all the time.

RED and WRED

You can use Random Early Detection (RED) or Weighted Random Early Detection (WRED) to avoid global TCP synchronization.

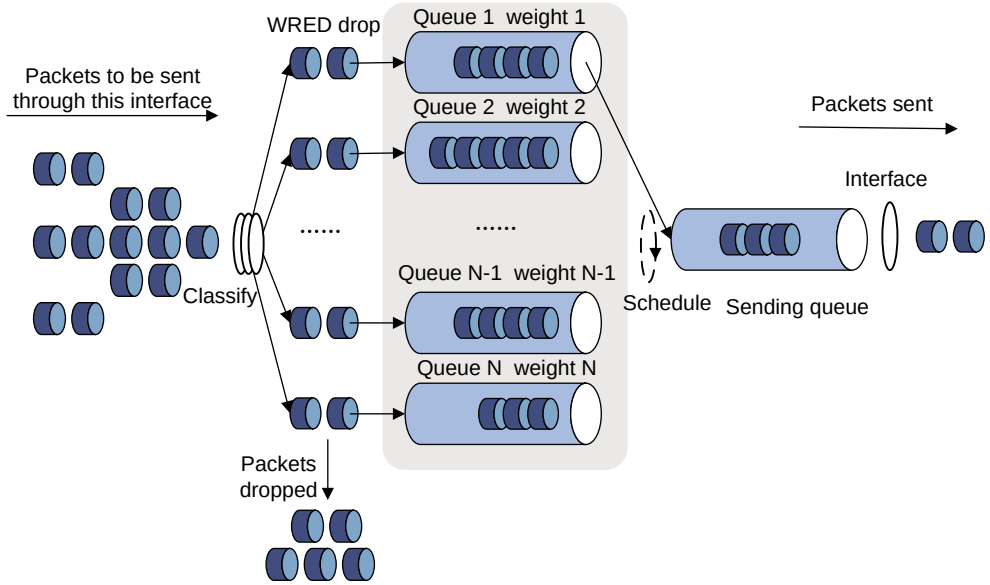
Both RED and WRED avoid global TCP synchronization by randomly dropping packets. When the sending rates of some TCP sessions slow down after their packets are dropped, other TCP sessions remain at high sending rates. Link bandwidth is efficiently used, because TCP sessions at high sending rates always exist.

The RED or WRED algorithm sets an upper threshold and lower threshold for each queue, and processes the packets in a queue as follows:

- When the queue size is shorter than the lower threshold, no packet is dropped.
- When the queue size reaches the upper threshold, all subsequent packets are dropped.
- When the queue size is between the lower threshold and the upper threshold, the received packets are dropped at random. The drop probability in a queue increases along with the queue size under the maximum drop probability.

If the current queue size is compared with the upper threshold and lower threshold to determine the drop policy, burst traffic is not fairly treated. To solve this problem, WRED compares the average queue size with the upper threshold and lower threshold to determine the drop probability.

The average queue size reflects the queue size change trend but is not sensitive to burst queue size changes, and burst traffic can be fairly treated.



When WFQ queuing is used, you can set the following parameters for packets with different precedence values to provide differentiated drop policies:

- Exponent for average queue size calculation.
- Upper threshold.
- Lower threshold.

- Drop probability.

Relationship between WRED and queuing mechanisms

Figure 16 Relationship between WRED and queuing mechanisms

Through combining WRED with WFQ, the flow-based WRED can be realized. Each flow has its own queue after classification.

- A flow with a smaller queue size has a lower packet drop probability.
- A flow with a larger queue size has a higher packet drop probability.

In this way, the benefits of the flow with a smaller queue size are protected.

ECN

By dropping packets, WRED alleviates the influence of congestion on the network. However, the network resources for transmitting packets from the sender to the device which drops the packets are wasted. When congestion occurs, it is a better idea to perform the following actions:

- Inform the sender of the congestion status.
- Have the sender proactively slow down the packet sending rate or decrease the window size of packets.

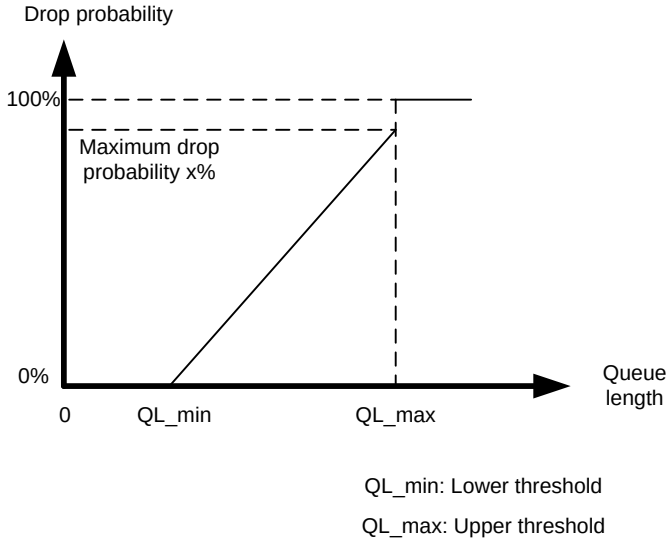
This better utilizes the network resources.

RFC 2481 defined an end-to-end congestion notification mechanism named Explicit Congestion Notification (ECN). ECN uses the DS field in the IP header to mark the congestion status along the packet transmission path. An ECN-capable endpoint can determine whether congestion occurs on the transmission path according to the packet contents. Then, it adjusts the packet sending speed to avoid deteriorating congestion. ECN defines the last two bits (ECN field) in the DS field of the IP header as follows:

- Bit 6 indicates whether the sending endpoint device supports ECN, and is called the ECN-Capable Transport (ECT) bit.
- Bit 7 indicates whether the packet has experienced congestion along the transmission path, and is called the Congestion Experienced (CE) bit.

For more information about the DS field, see "Appendixes."

In actual applications, the following packets are considered as packets that an ECN-capable endpoint transmits:



- Packets with ECT set to 1 and CE set to 0.
- Packets with ECT set to 0 and CE set to 1.

To enable ECN, do not specify ToS field bit 6 or 7 as the flag bit in iNQA, and vice versa. For more information about iNQA, see *Network Management and Monitoring Configuration Guide*.

As shown in Figure 17, the WRED algorithm sets an upper threshold and lower threshold for each queue, and processes the packets in a queue as follows if ECN is not enabled:

- When the queue size is shorter than the lower threshold, no packet is dropped.
- When the queue size reaches the upper threshold, all subsequent packets are dropped.
- When the queue size is between the lower threshold and the upper threshold, the received packets are dropped at random. The drop probability in a queue increases along with the queue size under the maximum drop probability.

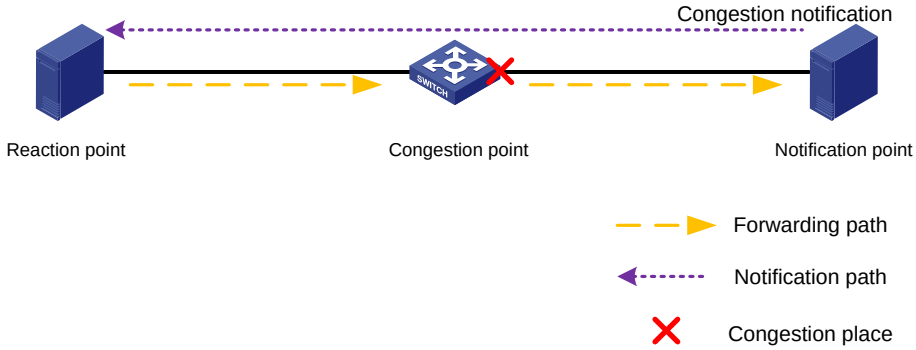


Figure 17 Drop probability and queue length

As shown in Figure 18, the network is deployed with ECN and has the following device roles:

- **Congestion point**—It forwards packets from the packet sender to the packet receiver. It supports ECN and can identify the ECN field. Congestion might occur on the congestion point. ECN must be configured on the congestion point.
- **Notification point**—It is an endpoint that receives packets. Its NIC supports ECN and can identify the ECN values 01, 10, and 11. After receiving a packet with the ECN field as 11, the notification point will notify the reaction point to slow down transmission by sending CE packets at the interval T1.
- **Reaction point**—It is an endpoint that sends packets. Its NIC supports ECN, and the ECN field of packets sent by it can be 01 or 10. After receiving a CE packet, the reaction point slows down transmission and starts a timer (T2, (T2>T1)). If the reaction point does not receive another CE packet when the timer expires, it considers that there is no congestion in the network and restores the previous transmission rate. If the reaction point receives another CE packet before the timer expires, it further reduces the transmission rate.

Figure 18 Network diagram with ECN enabled

After you enable ECN on the congestion point, it processes an incoming packet that enters an output queue as follows:

- When the average queue size is below the lower threshold, the congestion point forwards the packet without modifying the ECN field.
- When the average queue size is between the lower threshold and the upper threshold:
  - If the ECN field is 00, the packet comes from an ECN-incapable endpoint, and the congestion point determines whether to drop the packet according to the drop probability.
  - If the ECN field is 01 or 10, the packet comes from an ECN-capable endpoint, and the congestion point determines whether to modify the ECN field according to the drop probability and then forwards the packet. All packets will not be dropped.
  - If the ECN field is 11, the packet has experienced congestion along the transmission path, and the congestion point forwards the packet without modifying the ECN field.
- When the average queue size is above the upper threshold:
  - If the ECN field is 00, the packet comes from an ECN-incapable endpoint, and the congestion point drops the packet.
  - If the ECN field is 01 or 10, the packet comes from an ECN-capable endpoint, and the congestion point determines whether to modify the ECN field according to the drop probability and then forwards the packet. All packets will not be dropped.
  - If the ECN field is 11, the packet has experienced congestion along the transmission path, and the congestion point forwards the packet without modifying the ECN field.

Proper ECN thresholds can improve the network delay and throughput while alleviating congestion.

WRED parameters

Determine the following parameters before configuring WRED:

- **Upper threshold and lower threshold**—When the average queue size is smaller than the lower threshold, packets are not dropped. When the average queue size is between the lower threshold and the upper threshold, the packets are dropped at random. The longer the queue, the higher the drop probability. When the average queue size exceeds the upper threshold, subsequent packets are dropped.
- **Drop precedence**—A parameter used for packet drop. The value 0 corresponds to green packets, the value 1 corresponds to yellow packets, and the value 2 corresponds to red packets. Red packets are dropped preferentially.
- **Exponent for average queue size calculation**—The greater the exponent, the less sensitive the average queue size is to real-time queue size changes. The formula for calculating the average queue size is:

  Average queue size = (previous average queue size x $(1 – 2^{-n})$) + (current queue size x 2^{-n}), where n is the exponent.

- **Drop probability**—Drop probability in percentage. The greater the value, the higher the drop probability. (Applicable when you configure a WRED table on an interface.)

Configuring and applying a queue-based WRED table to an interface

Restrictions and guidelines

By using a WRED table, WRED randomly drops packets during congestion based on the queues that hold packets.

One WRED table can be applied to multiple interfaces. You can modify the parameters of a WRED table applied to an interface, but you cannot delete the WRED table.

The term "interface" in this section collectively refers to Layer 2 and Layer 3 Ethernet interfaces. You can use the **port link-mode** command to configure an Ethernet port as a Layer 2 or Layer 3 interface (see *Layer 2—LAN Switching Configuration Guide*).

Procedure

1. Enter system view.
   system-view
2. Create a WRED table and enter its view.
   qos wred queue table *table-name*
3. (Optional.) Set the WRED exponent for average queue size calculation.
   queue *queue-id* **weighting-constant** *exponent*
   The default setting is 9.
4. (Optional.) Configure the other WRED parameters.
   queue *queue-id* [**drop-level** *drop-level*] **low-limit** *low-limit* **high-limit** *high-limit* [**discard-probability** *discard-prob*]
   By default, the lower limit is 100, the higher limit is 1000, and the drop probability is 10%.
   If you configure the same value for the lower limit and higher limit and set the drop probability to 100%, tail drop is used for the queue.
5. Return to system view.
   quit
6. Enter interface view.
   interface *interface-type interface-number*
7. Apply the WRED table to the interface.
   qos wred apply [*table-name*]
   By default, no WRED table is applied to an interface, and tail drop is used on an interface.

Example: Configuring and applying a queue-based WRED table

Network configuration

Apply a WRED table to GigabitEthernet 1/0/2, so that the packets are dropped as follows when congestion occurs:

- For the interface to preferentially forward higher-priority traffic, set a lower drop probability for a queue with a greater queue number. Set different drop parameters for queue 0, queue 3, and queue 7.
- Drop packets according to their colors.
  - In queue 0, set the drop probability to 25%, 50%, and 75% for green, yellow, and red packets, respectively.
  - In queue 3, set the drop probability to 5%, 10%, and 25% for green, yellow, and red packets, respectively.
  - In queue 7, set the drop probability to 1%, 5%, and 10% for green, yellow, and red packets, respectively.

Procedure

Configure a queue-based WRED table, and set different drop parameters for packets with different drop levels in different queues.

```
<Sysname> system-view
[Sysname] qos wred queue table queue-table1
[Sysname-wred-table-queue-table1] queue 0 drop-level 0 low-limit 128 high-limit 512
discard-probability 25
[Sysname-wred-table-queue-table1] queue 0 drop-level 1 low-limit 128 high-limit 512
discard-probability 50
[Sysname-wred-table-queue-table1] queue 0 drop-level 2 low-limit 128 high-limit 512
discard-probability 75
[Sysname-wred-table-queue-table1] queue 3 drop-level 0 low-limit 256 high-limit 640
discard-probability 5
[Sysname-wred-table-queue-table1] queue 3 drop-level 1 low-limit 256 high-limit 640
discard-probability 10
[Sysname-wred-table-queue-table1] queue 3 drop-level 2 low-limit 256 high-limit 640
discard-probability 25
[Sysname-wred-table-queue-table1] queue 7 drop-level 0 low-limit 512 high-limit 1024
discard-probability 1
[Sysname-wred-table-queue-table1] queue 7 drop-level 1 low-limit 512 high-limit 1024
discard-probability 5
[Sysname-wred-table-queue-table1] queue 7 drop-level 2 low-limit 512 high-limit 1024
discard-probability 10
[Sysname-wred-table-queue-table1] quit
```

Apply the queue-based WRED table to GigabitEthernet 1/0/2.

```
[Sysname] interface gigabitethernet 1/0/2
[Sysname-GigabitEthernet1/0/2] qos wred apply queue-table1
[Sysname-GigabitEthernet1/0/2] quit
```

Display and maintenance commands for WRED

Execute **display** commands in any view.

Task	Command
Display WRED configuration and statistics for an interface.	**display qos wred interface** [*interface-type interface-number*]
Display the configuration of a WRED table or all WRED tables.	**display qos wred table** [**name** *table-name*] [**slot** *slot-number*]

Configuring traffic filtering

About traffic filtering

You can filter in or filter out traffic of a class by associating the class with a traffic filtering action. For example, you can filter packets sourced from an IP address according to network status.

Procedure

1. Enter system view.
   system-view
2. Define a traffic class.
   a. Create a traffic class and enter traffic class view.
      traffic classifier *classifier-name* [**operator** { **and** | **or** }]
   b. Configure a match criterion.
      if-match *match-criteria*
      By default, no match criterion is configured.
      For more information about configuring match criteria, see *ACL and QoS Command Reference*.
   c. Return to system view.
      quit
3. Define a traffic behavior.
   a. Create a traffic behavior and enter traffic behavior view.
      traffic behavior *behavior-name*
   b. Configure the traffic filtering action.
      filter { **deny** | **permit** }
      By default, no traffic filtering action is configured.
      If a traffic behavior has the **filter deny** action, all other actions in the traffic behavior except class-based accounting do not take effect.
      If a traffic behavior has the filter permit action, matching packets will not dropped by a lower-priority configuration even if the action of the lower-priority configuration is drop.
   c. Return to system view.
      quit
4. Define a QoS policy.
   a. Create a QoS policy and enter QoS policy view.
      qos policy *policy-name*
   b. Associate the traffic class with the traffic behavior in the QoS policy.
      classifier *classifier-name* **behavior** *behavior-name*
      By default, a traffic class is not associated with a traffic behavior.
   c. Return to system view.
      quit
5. Apply the QoS policy.
   For more information, see "Applying the QoS policy."

By default, no QoS policy is applied.

6. (Optional.) Display the traffic filtering configuration.

   display traffic behavior user-defined [*behavior-name*]

   This command is available in any view.

Traffic filtering configuration examples

Example: Configuring traffic filtering

Network configuration

As shown in Figure 19, configure traffic filtering on GigabitEthernet 1/0/1 to deny the incoming packets with destination port number 21.

Figure 19 Network diagram

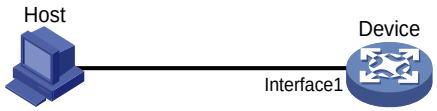

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Create advanced ACL 3000, and configure a rule to match packets whose destination port number is 21.

```
<Sysname> system-view
[Sysname] sysname Device
[Device] acl advanced 3000
[Device-acl-ipv4-adv-3000] rule 0 permit tcp destination-port eq 21
[Device-acl-ipv4-adv-3000] quit
```

Create a traffic class named **classifier_1**, and use ACL 3000 as the match criterion in the traffic class.

```
[Device] traffic classifier classifier_1
[Device-classifier-classifier_1] if-match acl 3000
[Device-classifier-classifier_1] quit
```

Create a traffic behavior named **behavior_1**, and configure the traffic filtering action to drop packets.

```
[Device] traffic behavior behavior_1
[Device-behavior-behavior_1] filter deny
[Device-behavior-behavior_1] quit
```

Create a QoS policy named **policy**, and associate traffic class **classifier_1** with traffic behavior **behavior_1** in the QoS policy.

```
[Device] qos policy policy
[Device-qospolicy-policy] classifier classifier_1 behavior behavior_1
[Device-qospolicy-policy] quit
```

Apply QoS policy **policy** to the incoming traffic of GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] qos apply policy policy inbound
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Use the **display qos policy interface** command to verify that the configuration has been performed successfully.

Configuration files

```
#
 sysname Device
#
traffic classifier classifier_1 operator and
 if-match acl 3000
#
traffic behavior behavior_1
 filter deny
#
qos policy policy
 classifier classifier_1 behavior behavior_1
#
interface GigabitEthernet1/0/1
 port link-mode bridge
 qos apply policy policy inbound
#
acl advanced 3000
 rule 0 permit tcp destination-port eq ftp
#
return
```

Configuring priority marking

About priority marking

Priority marking sets the priority fields or flag bits of packets to modify the priority of packets. For example, you can use priority marking to set IP precedence or DSCP for a class of IP packets to control the forwarding of these packets.

To configure priority marking to set the priority fields or flag bits for a class of packets, perform the following tasks:

1. Configure a traffic behavior with a priority marking action.
2. Associate the traffic class with the traffic behavior.

Priority marking can be used together with priority mapping. For more information, see "Configuring priority mapping."

Configuring priority marking

Restrictions and guidelines

The device supports the following application destinations for priority marking:

- Interface in the inbound direction.
- VLANs in the inbound direction.
- Globally in the inbound direction.

Procedure

1. Enter system view.
   system-view
2. Define a traffic class.
   a. Create a traffic class and enter traffic class view.
      traffic classifier *classifier-name* [**operator** { **and** | **or** }]
   b. Configure a match criterion.
      if-match *match-criteria*
      By default, no match criterion is configured.
      For more information about the **if-match** command, see *ACL and QoS Command Reference*.
   c. Return to system view.
      quit
3. Define a traffic behavior.
   a. Create a traffic behavior and enter traffic behavior view.
      traffic behavior *behavior-name*
   b. Configure a priority marking action.
      For configurable priority marking actions, see the **remark** commands in *ACL and QoS Command Reference*.
   c. Return to system view.
      quit
4. Define a QoS policy.

a. Create a QoS policy and enter QoS policy view.
qos policy *policy-name*

b. Associate the traffic class with the traffic behavior in the QoS policy.
classifier *classifier-name* **behavior** *behavior-name*
By default, a traffic class is not associated with a traffic behavior.

c. Return to system view.
quit

5. Apply the QoS policy.
For more information, see "Applying the QoS policy."
By default, no QoS policy is applied.

6. (Optional.) Display the priority marking configuration.
display traffic behavior user-defined [*behavior-name*]
This command is available in any view.

Configuring nesting

About nesting

Nesting adds a VLAN tag to the matching packets to allow the VLAN-tagged packets to pass through the corresponding VLAN. For example, you can add an outer VLAN tag to packets from a customer network to a service provider network. This allows the packets to pass through the service provider network by carrying a VLAN tag assigned by the service provider.

Restrictions and guidelines: Nesting configuration

A VLAN tag adding action takes effect only when a QoS policy is applied to the inbound direction of an interface, VLAN, or globally.

Procedure

1. Enter system view.
   system-view
2. Define a traffic class.
   a. Create a traffic class and enter traffic class view.
      traffic classifier *classifier-name* [**operator** { **and** | **or** }]
   b. Configure a match criterion.
      if-match *match-criteria*
      By default, no match criterion is configured for a traffic class.
      For more information about the match criteria, see the **if-match** command in *ACL and QoS Command Reference*.
   c. Return to system view.
      quit
3. Define a traffic behavior.
   a. Create a traffic behavior and enter traffic behavior view.
      traffic behavior *behavior-name*
   b. Configure an outer VLAN tag adding action.
      nest top-most vlan *vlan-id*
      By default, no outer VLAN tag adding action is configured for a traffic behavior.
   c. Return to system view.
      quit
4. Define a QoS policy.
   a. Create a QoS policy and enter QoS policy view.
      qos policy *policy-name*
   b. Associate the traffic class with the traffic behavior in the QoS policy.
      classifier *classifier-name* **behavior** *behavior-name*
      By default, a traffic class is not associated with a traffic behavior.
   c. Return to system view.

```
quit
```

5. Apply the QoS policy.

   For more information, see "Applying the QoS policy."

   By default, no QoS policy is applied.

6. (Optional.) Display the nesting configuration.

   display traffic behavior user-defined [*behavior-name*]

   This command is available in any view.

Nesting configuration examples

Example: Configuring nesting

Network configuration

As shown in Figure 20:

- Site 1 and Site 2 in VPN A are two branches of a company. They use VLAN 5 to transmit traffic.
- Because Site 1 and Site 2 are located in different areas, the two sites use the VPN access service of a service provider. The service provider assigns VLAN 100 to the two sites.

Configure nesting, so that the two branches can communicate through the service provider network.

Figure 20 Network diagram

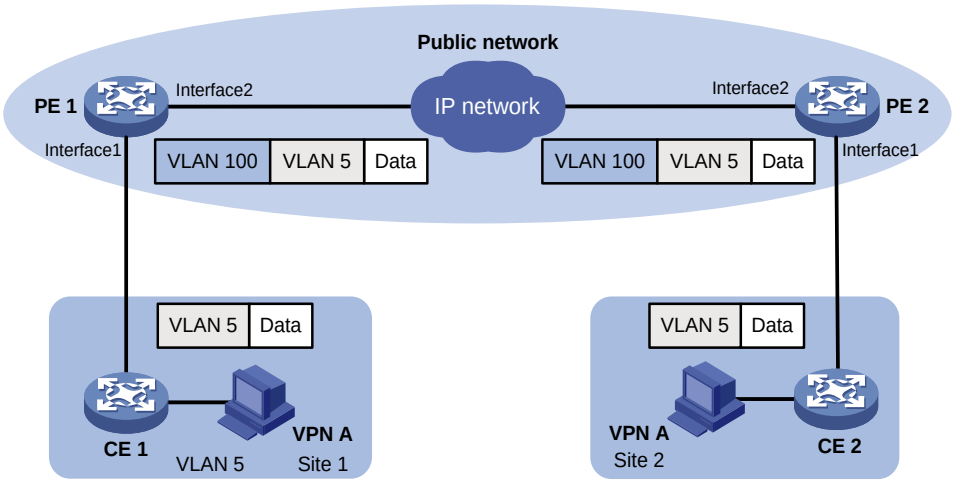

Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configuring PE 1:

   # Create a traffic class named **test** to match traffic with VLAN ID 5.

   ```
   <Sysname> system-view
   [Sysname] sysname PE1
   [PE1] traffic classifier test
   ```

```
[PE1-classifier-test] if-match service-vlan-id 5
[PE1-classifier-test] quit
```

Configure an action to add outer VLAN tag 100 in traffic behavior **test**.

```
[PE1] vlan 100
[PE1-vlan100] quit
[PE1] traffic behavior test
[PE1-behavior-test] nest top-most vlan 100
[PE1-behavior-test] quit
```

Create a QoS policy named **test**, and associate class **test** with behavior **test** in the QoS policy.

```
[PE1] qos policy test
[PE1-qospolicy-test] classifier test behavior test
[PE1-qospolicy-test] quit
```

Configure the downlink port (GigabitEthernet 1/0/1) as a hybrid port, and assign the port to VLAN 100 as an untagged member.

```
[PE1] interface gigabitethernet 1/0/1
[PE1-GigabitEthernet1/0/1] port link-type hybrid
[PE1-GigabitEthernet1/0/1] port hybrid vlan 100 untagged
```

Apply QoS policy **test** to the incoming traffic of GigabitEthernet 1/0/1.

```
[PE1-GigabitEthernet1/0/1] qos apply policy test inbound
[PE1-GigabitEthernet1/0/1] quit
```

Configure the uplink port (GigabitEthernet 1/0/2) as a trunk port, and assign it to VLAN 100.

```
[PE1] interface gigabitethernet 1/0/2
[PE1-GigabitEthernet1/0/2] port link-type trunk
[PE1-GigabitEthernet1/0/2] port trunk permit vlan 100
[PE1-GigabitEthernet1/0/2] quit
```

2. Configuring PE 2:

Create a traffic class named **test** to match traffic with VLAN ID 5.

```
<Sysname> system-view
[Sysname] sysname PE2
[PE2] traffic classifier test
[PE2-classifier-test] if-match service-vlan-id 5
[PE2-classifier-test] quit
```

Configure an action to add outer VLAN tag 100 in traffic behavior **test**.

```
[PE2] vlan 100
[PE2-vlan100] quit
[PE2] traffic behavior test
[PE2-behavior-test] nest top-most vlan 100
[PE2-behavior-test] quit
```

Create a QoS policy named **test**, and associate class **test** with behavior **test** in the QoS policy.

```
[PE2] qos policy test
[PE2-qospolicy-test] classifier test behavior test
[PE2-qospolicy-test] quit
```

Configure the downlink port (GigabitEthernet 1/0/1) as a hybrid port, and assign the port to VLAN 100 as an untagged member.

```
[PE2] interface gigabitethernet 1/0/1
[PE2-GigabitEthernet1/0/1] port link-type hybrid
```

```
[PE2-GigabitEthernet1/0/1] port hybrid vlan 100 untagged
```

Apply QoS policy **test** to the incoming traffic of GigabitEthernet 1/0/1.

```
[PE2-GigabitEthernet1/0/1] qos apply policy test inbound
[PE2-GigabitEthernet1/0/1] quit
```

Configure the uplink port (GigabitEthernet 1/0/2) as a trunk port, and assign it to VLAN 100.

```
[PE2] interface gigabitethernet 1/0/2
[PE2-GigabitEthernet1/0/2] port link-type trunk
[PE2-GigabitEthernet1/0/2] port trunk permit vlan 100
[PE2-GigabitEthernet1/0/2] quit
[PE2] commit
```

Verifying the configuration

Configuring traffic redirecting

About traffic redirecting

Traffic redirecting redirects packets matching the specified match criteria to a location for processing.

You can redirect packets to the following destinations:

- CPU.
- Interface.
- Next hop.

Restrictions and guidelines: Traffic redirecting configuration

- A traffic redirecting action takes effect only when a QoS policy is applied to the inbound direction of the following application destinations:
  - Interface.
  - VLANs.
  - Globally.
- If you execute the **redirect** command multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.
   system-view
2. Define a traffic class.
   a. Create a traffic class and enter traffic class view.
      traffic classifier *classifier-name* [**operator** { **and** | **or** }]
   b. Configure a match criterion.
      if-match *match-criteria*
      By default, no match criterion is configured for a traffic class.
      For more information about the match criteria, see the **if-match** command in *ACL and QoS Command Reference*.
   c. Return to system view.
      quit
3. Define a traffic behavior.
   a. Create a traffic behavior and enter traffic behavior view.
      traffic behavior *behavior-name*
   b. Configure a traffic redirecting action.
      See the **redirect** commands in the command reference.
      By default, no traffic redirecting action is configured for a traffic behavior.
   c. Return to system view.

quit

4. Define a QoS policy.
   a. Create a QoS policy and enter QoS policy view.
      qos policy *policy-name*
   b. Associate the traffic class with the traffic behavior in the QoS policy.
      classifier *classifier-name* **behavior** *behavior-name*
      By default, a traffic class is not associated with a traffic behavior.
   c. Return to system view.
      quit
5. Apply the QoS policy.
   For more information, see "Applying the QoS policy."
   By default, no QoS policy is applied.
6. (Optional.) Display traffic redirecting configuration.
   display traffic behavior user-defined [*behavior-name*]
   This command is available in any view.

Traffic redirecting configuration examples

Example: Configuring traffic redirecting

Network configuration

As shown in Figure 21:

- Device A is connected to Device B through two links. Device A and Device B are each connected to other devices.
- GigabitEthernet 1/0/1 of Device A is a trunk port and belongs to VLAN 200 and VLAN 201.
- GigabitEthernet 1/0/2 of Device A and GigabitEthernet 1/0/2 of Device B belong to VLAN 200.
- GigabitEthernet 1/0/3 of Device A and GigabitEthernet 1/0/3 of Device B belong to VLAN 201.
- On Device A, the IP address of VLAN-interface 200 is 200.1.1.1/24, and that of VLAN-interface 201 is 201.1.1.1/24.
- On Device B, the IP address of VLAN-interface 200 is 200.1.1.2/24, and that of VLAN-interface 201 is 201.1.1.2/24.

Configure the actions of redirecting traffic to an interface to meet the following requirements:

- Packets with source IP address 2.1.1.1 received on GigabitEthernet 1/0/1 of Device A are forwarded to GigabitEthernet 1/0/2.
- Packets with source IP address 2.1.1.2 received on GigabitEthernet 1/0/1 of Device A are forwarded to GigabitEthernet 1/0/3.
- Other packets received on GigabitEthernet 1/0/1 of Device A are forwarded according to the routing table.

Figure 21 Network diagram

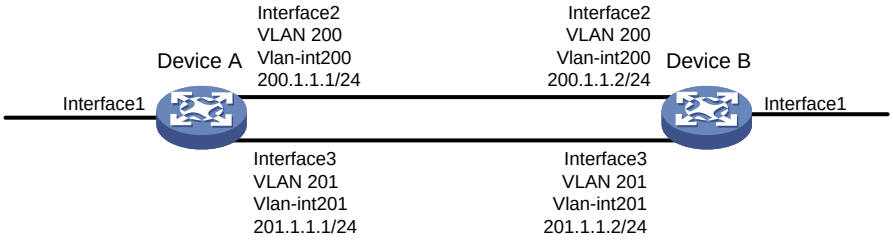

Table 6 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Create basic ACL 2000, and configure a rule to match packets with source IP address 2.1.1.1.

```
<Sysname> system-view
[Sysname] sysname DeviceA
[DeviceA] acl basic 2000
[DeviceA-acl-ipv4-basic-2000] rule permit source 2.1.1.1 0
[DeviceA-acl-ipv4-basic-2000] quit
```

Create basic ACL 2001, and configure a rule to match packets with source IP address 2.1.1.2.

```
[DeviceA] acl basic 2001
[DeviceA-acl-ipv4-basic-2001] rule permit source 2.1.1.2 0
[DeviceA-acl-ipv4-basic-2001] quit
```

Create a traffic class named **classifier_1**, and use ACL 2000 as the match criterion in the traffic class.

```
[DeviceA] traffic classifier classifier_1
[DeviceA-classifier-classifier_1] if-match acl 2000
[DeviceA-classifier-classifier_1] quit
```

Create a traffic class named **classifier_2**, and use ACL 2001 as the match criterion in the traffic class.

```
[DeviceA] traffic classifier classifier_2
[DeviceA-classifier-classifier_2] if-match acl 2001
[DeviceA-classifier-classifier_2] quit
```

Create a traffic behavior named **behavior_1**, and configure the action of redirecting traffic to GigabitEthernet 1/0/2.

```
[DeviceA] traffic behavior behavior_1
[DeviceA-behavior-behavior_1] redirect interface gigabitethernet 1/0/2
[DeviceA-behavior-behavior_1] quit
```

Create a traffic behavior named **behavior_2**, and configure the action of redirecting traffic to GigabitEthernet 1/0/3.

```
[DeviceA] traffic behavior behavior_2
[DeviceA-behavior-behavior_2] redirect interface gigabitethernet 1/0/3
[DeviceA-behavior-behavior_2] quit
```

Create a QoS policy named **policy**.

```
[DeviceA] qos policy policy
```

Associate traffic class **classifier_1** with traffic behavior **behavior_1** in the QoS policy.

```
[DeviceA-qospolicy-policy] classifier classifier_1 behavior behavior_1
```

Associate traffic class **classifier_2** with traffic behavior **behavior_2** in the QoS policy.

```
[DeviceA-qospolicy-policy] classifier classifier_2 behavior behavior_2
[DeviceA-qospolicy-policy] quit
```

Apply QoS policy **policy** to the incoming traffic of GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] qos apply policy policy inbound
[DeviceA-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Use the **`display qos policy interface`** command to verify that the configuration has been performed successfully.

Configuration files

```
#
 sysname DeviceA
#
traffic classifier classifier_1 operator and
 if-match acl 2000
#

return
```

Configuring global CAR

About global CAR

Global committed access rate (CAR) is an approach to policing traffic flows globally. It adds flexibility to common CAR where traffic policing is performed only on a per-traffic class or per-interface basis. In this approach, CAR actions are created in system view and each can be used to police multiple traffic flows as a whole.

Global CAR provides the following CAR actions: aggregate CAR and hierarchical CAR.

Aggregate CAR

An aggregate CAR action is created globally. It can be directly applied to interfaces or used in the traffic behaviors associated with different traffic classes to police multiple traffic flows as a whole. The total rate of the traffic flows must conform to the traffic policing specifications set in the aggregate CAR action.

Hierarchical CAR

A hierarchical CAR action is created globally. It must be used in conjunction with a common CAR or aggregate CAR action. With a hierarchical CAR action, you can limit the total traffic of multiple traffic classes.

A hierarchical CAR action can be used in the common or aggregate CAR action for a traffic class in either AND mode or OR mode.

- In AND mode, the rate of the traffic class is strictly limited under the common or aggregate CAR. This mode applies to flows that must be strictly rate limited.
- In OR mode, the traffic class can use idle bandwidth of other traffic classes associated with the hierarchical CAR. This mode applies to high priority, bursty traffic like video.

By using the two modes appropriately, you can improve bandwidth efficiency.

For example, suppose two flows exist: a low priority data flow and a high priority, bursty video flow. Their total traffic rate cannot exceed 4096 kbps and the video flow must be assured of at least 2048 kbps bandwidth. You can perform the following tasks:

- Configure common CAR actions to set the traffic rate to 2048 kbps for the two flows.
- Configure a hierarchical CAR action to limit their total traffic rate to 4096 kbps.
- Use the action in AND mode in the common CAR action for the data flow.
- Use the action in OR mode in the common CAR action for the video flow.

The video flow is assured of 2048 kbps bandwidth and can use idle bandwidth of the data flow.

In a bandwidth oversubscription scenario, the uplink port bandwidth is lower than the total downlink port traffic rate. You can use hierarchical CAR to meet the following requirements:

- Limit the total rate of downlink port traffic.
- Allow each downlink port to forward traffic at the maximum rate when the other ports are idle.

For example, you can perform the following tasks:

- Use common CAR actions to limit the rates of Internet access flow 1 and flow 2 to both 128 kbps.
- Use a hierarchical CAR action to limit their total traffic rate to 192 kbps.

- Use the hierarchical CAR action for both flow 1 and flow 2 in AND mode.

When flow 1 is not present, flow 2 is transmitted at the maximum rate, 128 kbps. When both flows are present, the total rate of the two flows cannot exceed 192 kbps. As a result, the traffic rate of flow 2 might drop below 128 kbps.

Restrictions and guidelines: Global CAR configuration

The device supports only aggregate CAR in the current software version, and an aggregate CAR action cannot be applied in both the inbound direction and outbound direction.

When a QoS policy containing an aggregate CAR action is applied on an IRF fabric, the traffic matching the QoS policy might enter the IRF fabric through interfaces on different IRF member devices. In this case, the actual rate limit that takes effect is the sum of the CIR and PIR in the aggregate CAR action multiplied by the number of involved IRF member devices by default.

Configuring aggregate CAR

1. Enter system view.

   system-view
2. Define a traffic class.
   a. Create a traffic class and enter traffic class view.

      traffic classifier *classifier-name* [**operator** { **and** | **or** }]
   b. Configure a match criterion.

      if-match *match-criteria*

      By default, no match criterion is configured.

      For configurable match criteria, see the **if-match** command in *ACL and QoS Command Reference*.
   c. Return to system view.

      quit
3. Configure an aggregate CAR action.

   qos car *car-name* **aggregative cir** *committed-information-rate* [**cbs** *committed-burst-size* [**ebs** *excess-burst-size*]] [**green** *action* | **red** *action* | **yellow** *action*] *

   qos car *car-name* **aggregative cir** *committed-information-rate* [**cbs** *committed-burst-size*] **pir** *peak-information-rate* [**ebs** *excess-burst-size*] [**green** *action* | **red** *action* | **yellow** *action*] *

   By default, no aggregate CAR action is configured.
4. Define a traffic behavior.
   a. Enter traffic behavior view.

      traffic behavior *behavior-name*
   b. Use the aggregate CAR in the traffic behavior.

      car name *car-name*

      By default, no aggregate CAR action is used in a traffic behavior.
5. Apply the QoS policy.

   For more information, see "Applying the QoS policy."

   By default, no QoS policy is applied.

Display and maintenance commands for global CAR

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display statistics for global CAR actions.	**display qos car name** [*car-name*]
Clear statistics for global CAR actions.	**reset qos car name** [*car-name*]

Global CAR configuration examples

Example: Configuring MQC aggregate CAR

Network configuration

As shown in Figure 22, configure MQC aggregate CAR to limit the total rate of traffic in VLAN 10 and VLAN 100 to CIR 2560 kbps and CBS 20480 bytes and drop the exceeding packets.

Figure 22 Network diagram

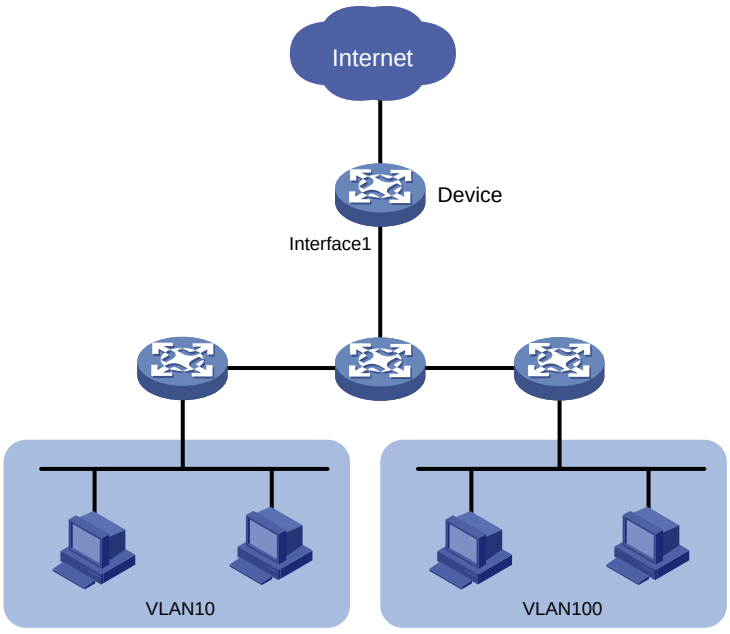

Table 7 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Configure an aggregate CAR action according to the rate limit requirements.

```
<Sysname> system-view
[Sysname] sysname Device
```

```
[Device] qos car aggcar-1 aggregative cir 2560 cbs 20480 red discard
```

Create traffic class 1, and use VLAN ID 10 as the match criterion in the traffic class.

```
[Device] traffic classifier 1
[Device-classifier-1] if-match service-vlan-id 10
[Device-classifier-1] quit
```

Create traffic behavior 1, and use the aggregate CAR action in the traffic behavior.

```
[Device] traffic behavior 1
[Device-behavior-1] car name aggcar-1
[Device-behavior-1] quit
```

Create traffic class 2, and use VLAN ID 100 as the match criterion in the traffic class.

```
[Device] traffic classifier 2
[Device-classifier-2] if-match service-vlan-id 100
[Device-classifier-2] quit
```

Create traffic behavior 2, and use the aggregate CAR action in the traffic behavior.

```
[Device] traffic behavior 2
[Device-behavior-2] car name aggcar-1
[Device-behavior-2] quit
```

Create a QoS policy named **car**, and associate traffic classes 1 and 2 with traffic behaviors 1 and 2 in the QoS policy, respectively.

```
[Device] qos policy car
[Device-qospolicy-car] classifier 1 behavior 1
[Device-qospolicy-car] classifier 2 behavior 2
[Device-qospolicy-car] quit
```

Apply QoS policy **car** to the incoming traffic of GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] qos apply policy car inbound
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Use the **display qos policy interface** command to verify that the configuration has been performed successfully.

Configuration files

```
#
 sysname Device
#
 qos car aggcar-1 aggregative cir 2560 cbs 20480 ebs 0 green pass red discard yellow pass
#
traffic classifier 1 operator and
 if-match service-vlan-id 10
#
traffic classifier 2 operator and
 if-match service-vlan-id 100
#
traffic behavior 1
 car name aggcar-1
#
traffic behavior 2
```

```
 car name aggcar-1
#
qos policy car
 classifier 1 behavior 1
 classifier 2 behavior 2
#
interface GigabitEthernet1/0/1
 port link-mode bridge
 qos apply policy car inbound
#
return
```

Configuring class-based accounting

About class-based accounting

Class-based accounting collects statistics on a per-traffic class basis. For example, you can define the action to collect statistics for traffic sourced from a certain IP address. By analyzing the statistics, you can determine whether anomalies have occurred and what action to take.

Procedure

1. Enter system view.
   system-view
2. Define a traffic class.
   a. Create a traffic class and enter traffic class view.
      traffic classifier *classifier-name* [**operator** { **and** | **or** }]
   b. Configure a match criterion.
      if-match *match-criteria*
      By default, no match criterion is configured.
      For more information about the **if-match** command, see *ACL and QoS Command Reference*.
   c. Return to system view.
      quit
3. Define a traffic behavior.
   a. Create a traffic behavior and enter traffic behavior view.
      traffic behavior *behavior-name*
   b. Configure an accounting action.
      accounting [**byte** | **packet**]
      By default, no traffic accounting action is configured.
   c. Return to system view.
      quit
4. Define a QoS policy.
   a. Create a QoS policy and enter QoS policy view.
      qos policy *policy-name*
   b. Associate the traffic class with the traffic behavior in the QoS policy.
      classifier *classifier-name* **behavior** *behavior-name*
      By default, a traffic class is not associated with a traffic behavior.
   c. Return to system view.
      quit
5. Apply the QoS policy.
   For more information, see "Applying the QoS policy."
   By default, no QoS policy is applied.
6. (Optional.) Display the class-based accounting configuration.
   display traffic behavior user-defined [*behavior-name*]

Class-based accounting configuration examples

Example: Configuring class-based accounting

Network configuration

As shown in Figure 23, configure class-based accounting on GigabitEthernet 1/0/1 to collect statistics for incoming traffic from 1.1.1.1/24.

Figure 23 Network diagram

Table 8 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Create basic ACL 2000, and configure a rule to match packets with source IP address 1.1.1.1.

```
<Sysname> system-view
[Sysname] sysname Device
[Device] acl basic 2000
[Device-acl-ipv4-basic-2000] rule permit source 1.1.1.1 0
[Device-acl-ipv4-basic-2000] quit
```

Create a traffic class named **classifier_1**, and use ACL 2000 as the match criterion in the traffic class.

```
[Device] traffic classifier classifier_1
[Device-classifier-classifier_1] if-match acl 2000
[Device-classifier-classifier_1] quit
```

Create a traffic behavior named **behavior_1**, and configure the class-based accounting action.

```
[Device] traffic behavior behavior_1
[Device-behavior-behavior_1] accounting packet
[Device-behavior-behavior_1] quit
```

Create a QoS policy named **policy**, and associate traffic class **classifier_1** with traffic behavior **behavior_1** in the QoS policy.

```
[Device] qos policy policy
[Device-qospolicy-policy] classifier classifier_1 behavior behavior_1
[Device-qospolicy-policy] quit
```

Apply QoS policy **policy** to the incoming traffic of GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] qos apply policy policy inbound
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Display traffic statistics to verify the configuration.

```
[Device] display qos policy interface gigabitethernet 1/0/1
Interface: GigabitEthernet1/0/1
  Direction: Inbound
  Policy: policy
   Classifier: classifier_1
     Operator: AND
     Rule(s) :
      If-match acl 2000
     Behavior: behavior_1
      Accounting enable:
        28529 (Packets)
```

Configuration files

```
#
 sysname Device
#
traffic classifier classifier_1 operator and
 if-match acl 2000
#
traffic behavior behavior_1
 accounting packet
#
qos policy policy
 classifier classifier_1 behavior behavior_1
#
interface GigabitEthernet1/0/1
 port link-mode bridge
 qos apply policy policy inbound
#
acl basic 2000
 rule 5 permit source 1.1.1.1 0
#
return
```

Setting an alarm threshold for protocol packets

About an alarm threshold for protocol packets

The device generates an alarm when the rate of protocol packets sent to the CPU exceeds the alarm threshold.

Restrictions and guidelines: Alarm threshold for protocol packets configuration

This feature does not support the **commit** command to deploy target configuration. For more information about target configuration, see target configuration management in *Fundamentals Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Set an alarm threshold for protocol packets sent to the CPU.
   qos soft-car protocol *protocol-type* **alarm-threshold** *alarm-threshold-rate* **slot** *slot-number*
   By default, the device does not generate alarms for protocol packets sent to the CPU.

Display and maintenance commands for alarm threshold for protocol packets

Execute **display** commands in any view.

Task	Command
Display the alarm threshold configuration for protocol packets.	**display qos soft-car protocol** [*protocol-type*] **slot** *slot-number*

Appendix C Introduction to packet precedence

IP precedence and DSCP values

Figure 24 ToS and DS fields

As shown in Figure 24, the ToS field in the IP header contains 8 bits. The first 3 bits (0 to 2) represent IP precedence from 0 to 7. According to RFC 2474, the ToS field is redefined as the differentiated services (DS) field. A DSCP value is represented by the first 6 bits (0 to 5) of the DS field and is in the range 0 to 63. The remaining 2 bits (6 and 7) are reserved.

Table 13 IP precedence

802.1p priority

802.1p priority lies in the Layer 2 header. It applies to occasions where Layer 3 header analysis is not needed and QoS must be assured at Layer 2.

Figure 25 An Ethernet frame with an 802.1Q tag header

As shown in Figure 25, the 4-byte 802.1Q tag header contains the 2-byte tag protocol identifier (TPID) and the 2-byte tag control information (TCI). The value of the TPID is 0x8100. Figure 26 shows the format of the 802.1Q tag header. The Priority field in the 802.1Q tag header is called 802.1p priority, because its use is defined in IEEE 802.1p. Figure 26Table 15 shows the values for 802.1p priority.

Figure 26 802.1Q tag header

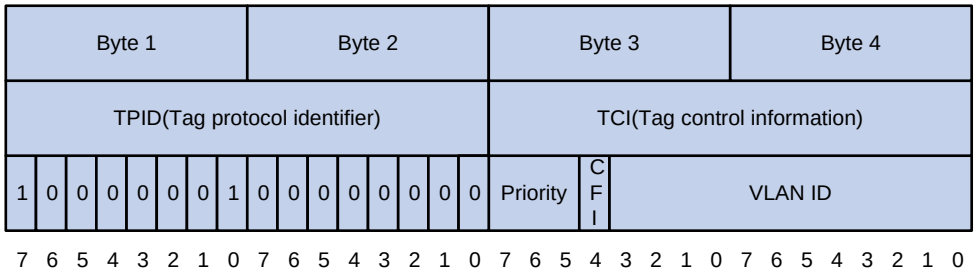

Table 15 Description on 802.1p priority

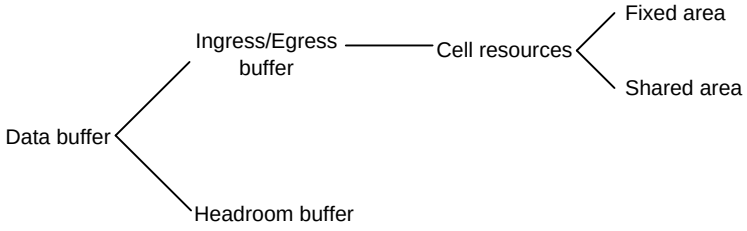
Configuring data buffers

About data buffers

Sudden traffic in a short period on the network might cause congestion, while device interfaces have limited processing capabilities, potentially leading to packet loss. Therefore, high-speed forwarding devices use data buffers to cache packets, reducing the probability of packet loss due to congestion. If the network experiences significant sudden traffic, resources in the data buffer might be exhausted, making it impossible to continue caching packets, which might still be discarded. Properly allocating data buffer resources allows high-priority queues or interface traffic to be cached, minimizing congestion impact.

The size and processing capability of the buffer depend entirely on the hardware forwarding chip and interfaces. Generally, all interfaces on the forwarding chip share the chip's data buffer resources, while queues on an interface share the interface's data buffer resources.



Data buffer types

The following data buffers are available:

- **Ingress buffer**—Stores incoming packets when the CPU is busy.
- **Egress buffer**—Stores outgoing packets when network congestion occurs.
- **Headroom buffer**—Stores packets when the ingress buffer or egress buffer is used up. The headroom buffer is mainly used for the Priority-based Flow Control (PFC) feature. There is a period of time between when the local PFC triggers the sending of the PFC PAUSE frame and when the peer end stops sending packets. During this period of time, the local device uses the headroom data buffer to cache packets. For more information about PFC, see PFC configuration in *Intelligent Lossless Network Configuration Guide*.

Figure 1 shows the structure of ingress and egress buffers.

Figure 1 Data buffer structure

Cell resources

A buffer uses cell resources to store packets based on packet sizes. Suppose a cell resource provides 208 bytes. The buffer allocates one cell resource to a 128-byte packet and two cell resources to a 300-byte packet.

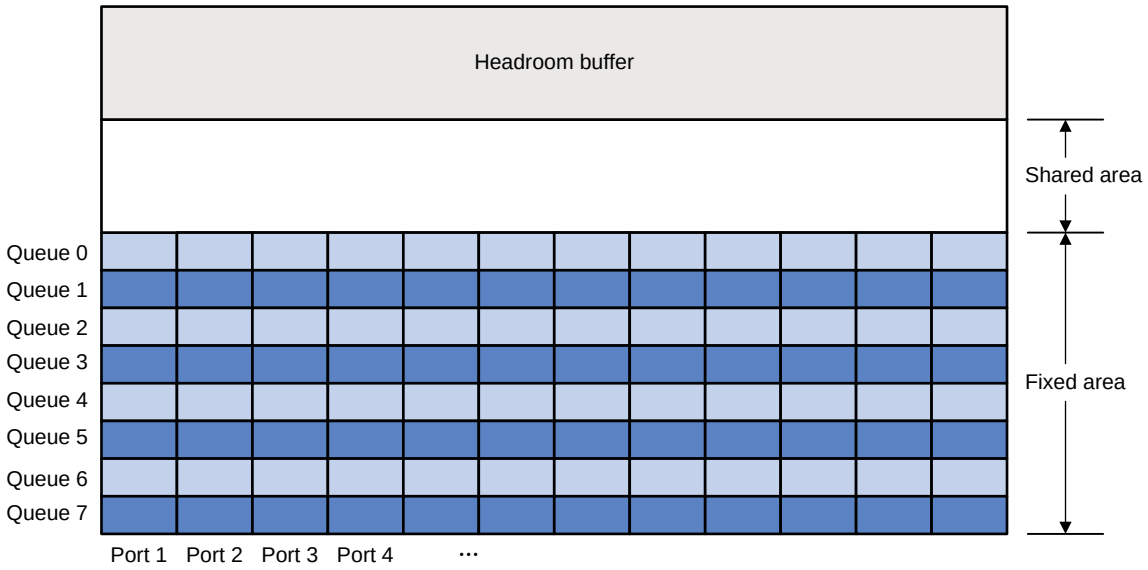
Fixed area and shared area

The cell resources have a fixed area and a shared area.

- **Fixed area**—Partitioned into queues, each of which is equally divided by all the interfaces on the switch, as shown in Figure 2.When congestion occurs or the CPU is busy, the following rules apply:

a. An interface first uses the relevant queues of the fixed area to store packets.

b. When a queue is full, the interface uses the corresponding queue of the shared area.



c. When the queue in the shared area is also full, the interface discards subsequent packets.

The system allocates the fixed area among queues as specified by the user. Even if a queue is not full, other queues cannot preempt its space. Similarly, the share of a queue for an interface cannot be preempted by other interfaces even if it is not full.

- **Shared area**—Partitioned into queues, each of which is not equally divided by the interfaces, as shown in Figure 2. The system determines the actual shared-area space for each queue according to user configuration and the number of packets actually received and sent. If a queue is not full, other queues can preempt its space.

  The system puts packets received or sent on all interfaces into a queue in the order they arrive. When the queue is full, subsequent packets are dropped.

Figure 2 Fixed area and shared area

Restrictions and guidelines: Data buffer configuration

IRF physical interfaces do not support this feature.

Data buffer tasks at a glance

To configure the data buffer, perform the following tasks:

- (Optional.) Configuring data buffer alarms
  - Configuring per-interface alarm thresholds for the ingress or egress buffer
  - Configuring per-queue alarm thresholds for the ingress or egress buffer
  - Configuring per-interface alarm thresholds for the Headroom buffer
  - Configuring packet-drop alarms

Configuring data buffer alarms

About data buffer alarms

This feature works with a network management system (such as IMC). Data buffer alarms include threshold-crossing alarms and packet drop alarms. The device reports these alarms to the network management system for displaying the data buffer usage.

You can configure data buffer alarms on a per-interface basis or a per-queue basis.

Restrictions and guidelines for data buffer alarm configuration

Configuring per-queue alarm thresholds is supported for only the egress buffer.

Configuring per-interface alarm thresholds for the ingress or egress buffer

1. Enter system view.

   system-view
2. Configure the alarm thresholds. Choose the options to configure as needed:
   - Configure the global alarm threshold.

     buffer { **egress** | **ingress** } **usage threshold slot** *slot-number* **null-queue ratio** *ratio*

     The default setting is 100%.
   - Execute the following commands in sequence to configure the alarm threshold on an interface:

     interface *interface-type interface-number*

     port buffer { **egress** | **ingress** } **usage threshold null-queue ratio** *ratio*

     By default, an interface uses the global alarm threshold.

   If you configure both the global alarm threshold and the alarm threshold on an interface, the latter takes effect.
3. Enable threshold-crossing alarms.

   buffer threshold alarm { **egress** | **ingress** } **enable**

   By default, threshold-crossing alarms are disabled.
4. (Optional.) Set the interval for sending threshold-crossing alarms.

   buffer threshold alarm { **egress** | **ingress** } **interval** *interval*

   The default setting is 5 seconds.

Configuring per-queue alarm thresholds for the ingress or egress buffer

1. Enter system view.

   system-view
2. Configure the alarm thresholds.

- Execute the following commands in sequence to configure the alarm threshold for a queue on an interface:

  interface *interface-type interface-number*

  buffer egress usage threshold queue *queue-id* **ratio** *ratio*

  The default setting is 100%.

3. Enable threshold-crossing alarms.

   buffer threshold alarm { **egress** | **ingress** } **enable**

   By default, threshold-crossing alarms are disabled.

4. (Optional.) Set the interval for sending threshold-crossing alarms.

   buffer threshold alarm { **egress** | **ingress** } **interval** *interval*

   The default setting is 5 seconds.

Configuring per-interface alarm thresholds for the Headroom buffer

1. Enter system view.

   system-view

2. Configure the alarm thresholds. Choose the options to configure as needed:
   - Configure the global alarm threshold.

     buffer usage threshold headroom slot *slot-number* **ratio** *ratio*

     The default setting is 100%.
   - Execute the following commands in sequence to configure the alarm threshold on an interface:

     interface *interface-type interface-number*

     port buffer usage threshold headroom null-queue ratio *ratio*

     By default, an interface uses the global alarm threshold.

   If you configure both the global alarm threshold and the alarm threshold on an interface, the latter takes effect.

3. Enable threshold-crossing alarms.

   buffer threshold alarm headroom enable

   By default, threshold-crossing alarms are disabled.

4. (Optional.) Set the interval for sending threshold-crossing alarms.

   buffer threshold alarm headroom interval *interval*

   The default setting is 5 seconds.

Configuring packet-drop alarms

About this task

This feature allows the device to periodically send packet-drop information to the NMS.

Restrictions and guidelines

This feature does not take effect on the Headroom buffer.

Procedure

1. Enter system view.

   system-view

2. Enable packet-drop alarms.

   buffer packet-drop alarm enable

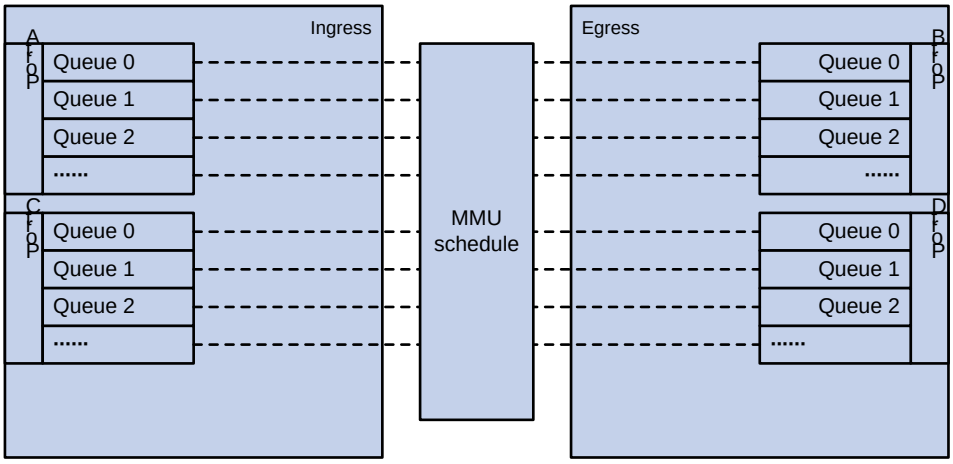
   By default, packet-drop alarms are disabled.

3. (Optional.) Set the interval for sending packet-drop alarms.

   buffer packet-drop alarm interval *interval*

   The default setting is 5 seconds.

Configuring TCB



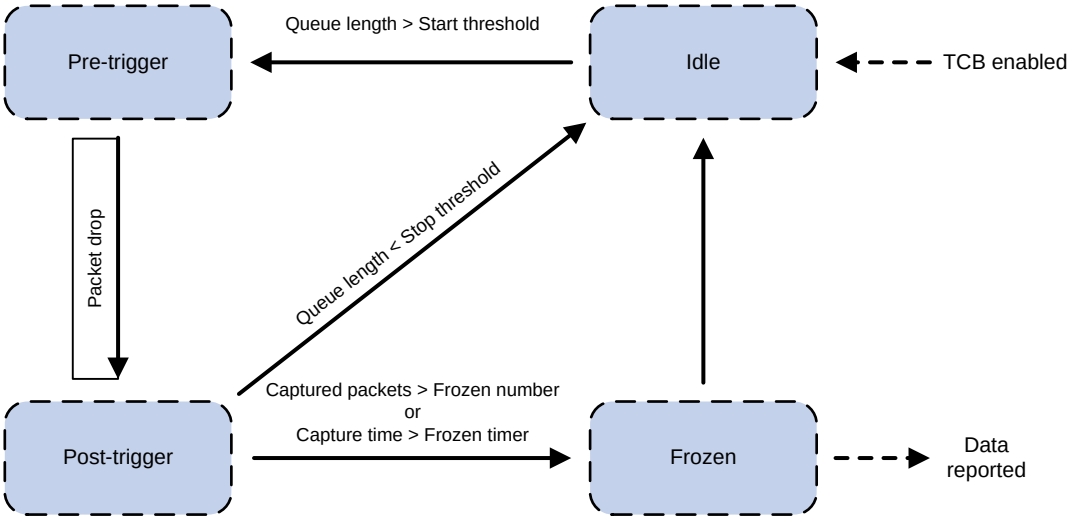
About TCB

Overview

The Transient Capture Buffer (TCB) feature monitors packet drop events on a set of memory management unit (MMU) resources. When a packet is dropped on a queue, the system collects drop time, drop reason, packet metadata, and other information and reports them to an NMS through gRPC.

An MMU manages the allocation of the ingress buffer and egress buffer and flexibly schedules queues to deal with traffic bursts.

Figure 3 MMU queues



How TBC works

The TCB state machine works as follows:

1. The state machine enters the idle state when TCB is enabled.
2. When the queue length is greater than *start-threshold-value*, the state machine transitions from the idle state to the pre-trigger state. The system captures packets by using the **pre-sample-rate**.
3. When packet drops occur on the queue, the state machine transitions from the pre-trigger to the post-trigger state.
4. When the queue length is smaller than *stop-threshold-value*, the state machine transitions from the post-trigger to the idle state. The system stops capturing packets.
5. When the queue length is greater than *start-threshold-value*, step 2 is repeated.

6. When the number of captured packets reaches the *frozen-number* or the capture timer expires, the state machine transitions from the post-trigger to the frozen state.
7. The state machine analyzes the drop reason and dropped packet characteristics and sends the analysis results to the gRPC module, which reports them to an NMS.
8. The state machine transitions from the frozen to the idle state.

Figure 4 TCB state machine

Restrictions and guidelines: TCB configuration

You can configure TCB in system view or interface view, but not in both views at the same time. For example, if you have configured TCB in system view, to configure TCB in interface view, you must first delete the TCB configuration in system view.

The TCB configuration in system view takes effect on all TCB-capable interfaces. The TCB configuration in interface view takes effect only on the specified interface.

Only one interface on the device can be configured with TCB when you configure TCB in interface view.

TCB cannot identify tunnel-encapsulated TCP or UDP packets if local analysis is enabled or an ACL is referenced.

During congestion, packet drop information is displayed for only TCP or UDP packets.

The gRPC sampling paths for TCB are **tcb/tcbpacketinfoevent** and **tcb/tcbrawpacketinfoevent**. For more information about gRPC, see "Configuring gRPC."

Enabling and configuring TCB

Enabling and configuring TCB in system view

1. Enter system view.

   system-view
2. Enable and configure TCB.

   buffer transient-capture global [**slot** *slot-number*] **egress enable** [**no-local-analysis**] [**acl**{ *ipv4-acl-number*|**name** *ipv4-acl-name*}]

[**start-threshold** *start-threshold-value* **stop-threshold** *stop-threshold-value*] [**frozen-number** *frozen-number* **frozen-timer** *timer-value*] [**pre-sample-rate** *pre-sample-rate* **post-sample-rate** *post-sample-rate*] [**poll-frequency** *frequency-value*]

By default, TCB is disabled.

Enabling and configuring TCB in interface view

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable and configure TCB.

   buffer transient-capture egress [**queue** *queue-id*] **enable** [**no-local-analysis**] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* }] [**start-threshold** *start-threshold-value* **stop-threshold** *stop-threshold-value*] [**frozen-number** *frozen-number* **frozen-timer** *timer-value*] [**pre-sample-rate** *pre-sample-rate* **post-sample-rate** *post-sample-rate*] [**poll-frequency** *frequency-value*]

   By default, TCB is disabled.

Display and maintenance commands for TCB

Execute **display** commands in any view.

Task	Command
Display packet drop information.	**display buffer transient-capture packet-drop slot** *slot-number* { **ethernet** | **ipv4** | **ipv6** }

TCB configuration examples

Example: Configuring TCB on an interface

Network configuration

As shown in Figure 5, configure TCB and gRPC on the device to monitor packet drops and report packet drop information to the collector through gRPC.

Figure 5 Network diagram

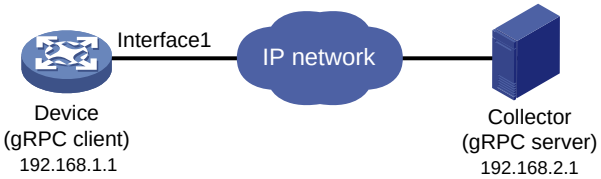


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Assign IP addresses to the device and the collector and configure routes. Make sure the network connections are available. (Details not shown.)
2. Configure TCB:

   # Create an IPv4 advanced ACL numbered 3001, and configure a rule to match packets with source IP address 192.168.5.2.

   ```
   <Device> system-view
   [Device] acl advanced 3001
   [Device-acl-ipv4-adv-3001] rule permit ip source 192.168.5.2 0
   [Device-acl-ipv4-adv-3001] quit
   ```

   # Configure TCB on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] buffer transient-capture egress queue 1 enable no-local-analysis acl 3001 start-threshold 10000 stop-threshold 5000 frozen-number 1000 frozen-timer 400 pre-sample-rate 10 post-sample-rate 10 poll-frequency 600
   [Device-GigabitEthernet1/0/1] quit
   ```

3. Configure gRPC:

   # Enable the gRPC service.

   ```
   [Device] grpc enable
   ```

   # Create a sensor group named **test**, and add sensor paths **tcb/tcbpacketinfoevent** and **tcb/tcbrawpacketinfoevent**.

   ```
   [Device] telemetry
   [Device-telemetry] sensor-group test
   [Device-telemetry-sensor-group-test] sensor path tcb/tcbpacketinfoevent
   [Device-telemetry-sensor-group-test] sensor path tcb/tcbrawpacketinfoevent
   [Device-telemetry-sensor-group-test] quit
   ```

   # Create a destination group named **collector1**. Specify a collector that uses IPv4 address 192.168.2.1 and port number 50050.

   ```
   [Device-telemetry] destination-group collector1
   [Device-telemetry-destination-group-collector1] ipv4-address 192.168.2.1 port 50050
   [Device-telemetry-destination-group-collector1] quit
   ```

   # Configure a subscription named **A** to bind sensor group **test** with destination group **collector1**. Set the sampling interval to 10 seconds.

   ```
   [Device-telemetry] subscription A
   [Device-telemetry-subscription-A] sensor-group test sample-interval 10
   [Device-telemetry-subscription-A] destination-group collector1
   [Device-telemetry-subscription-A] quit
   [Device-telemetry] quit
   ```

Verifying the configuration

Verify that the collector receives packet drop information when packet drops occur on a queue enabled with TCB. (Details not shown.)

Configuring time ranges 1
About time ranges 1
Restrictions and guidelines: Time range configuration 1
Procedure 1
Display and maintenance commands for time ranges 1
Time range configuration examples 2
Example: Configuring a time range 2

Configuring time ranges

About time ranges

You can implement a service based on the time of the day by applying a time range to it. A time-based service takes effect only in time periods specified by the time range. For example, you can implement time-based ACL rules by applying a time range to them.

The following basic types of time ranges are available:

- **Periodic time range**—Recurs periodically on a day or days of the week.
- **Absolute time range**—Represents only a period of time and does not recur.

The active period of a time range is calculated as follows:

1. Combining all periodic statements.
2. Combining all absolute statements.
3. Taking the intersection of the two statement sets as the active period of the time range.

Restrictions and guidelines: Time range configuration

When you configure the ACL hardware mode, follow these restrictions and guidelines:

- If a time range does not exist, the service based on the time range does not take effect.
- You can create a maximum of 1024 time ranges, each with a maximum of 32 periodic statements and 12 absolute statements.

Procedure

1. Enter system view.

   system-view

2. Create or edit a time range.

   time-range *time-range-name* { *start-time* **to** *end-time days* [**from** *time1 date1*] [**to** *time2 date2*] | **from** *time1 date1* [**to** *time2 date2*] | **to** *time2 date2* }

   If an existing time range name is provided, this command adds a statement to the time range.

Display and maintenance commands for time ranges

Execute the **display** command in any view.

Task	Command
Display time range configuration and status.	**display time-range** { *time-range-name* | **all** }

Time range configuration examples

Example: Configuring a time range

Network configuration

As shown in Figure 1, configure an ACL on the device to allow Host A to access the server only during 8:00 and 18:00 on working days from June 2015 to the end of the year.

Figure 1 Network diagram

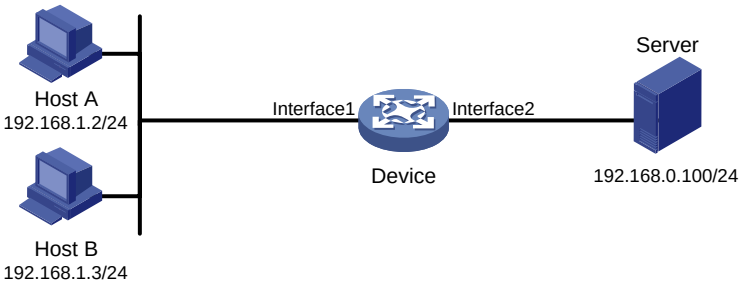

Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

Create a periodic time range during 8:00 and 18:00 on working days from June 2015 to the end of the year.

```
<Device> system-view
[Device] time-range work 8:0 to 18:0 working-day from 0:0 6/1/2015 to 24:00 12/31/2015
```

Create an IPv4 basic ACL numbered 2001, and configure a rule in the ACL to permit packets only from 192.168.1.2/32 during the time range **work**.

```
[Device] acl basic 2001
[Device-acl-ipv4-basic-2001] rule permit source 192.168.1.2 0 time-range work
[Device-acl-ipv4-basic-2001] rule deny source any time-range work
[Device-acl-ipv4-basic-2001] quit
```

Apply IPv4 basic ACL 2001 to filter outgoing packets on GigabitEthernet 1/0/2.

```
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] packet-filter 2001 outbound
[Device-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Verify that the time range **work** is active on the device.

```
[Device] display time-range all
Current time is 13:58:35 6/19/2015 Friday

Time-range : work (Active)
 08:00 to 18:00 working-day
 from 00:00 6/1/2015 to 00:00 1/1/2016
```

All contents in this document, including statements, information, and recommendations, are believed to be accurate, but they are presented without warranty of any kind, express or implied. H3C shall not be liable for technical or editorial errors or omissions contained herein.

Preface

This configuration guide describes the security fundamentals and configuration procedures.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators working with the S5570S-EI and S5500V3-SI switch series.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

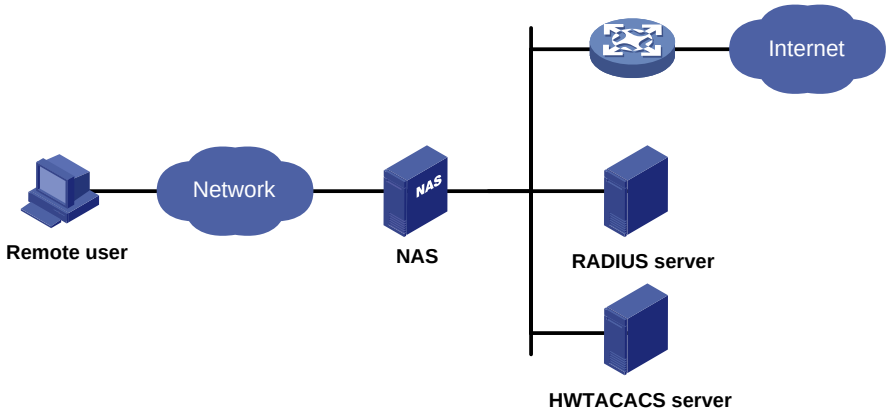
Configuring AAA

About AAA

AAA implementation



Authentication, Authorization, and Accounting (AAA) provides a uniform framework for implementing network access management. This feature specifies the following security functions:

- **Authentication**—Identifies users and verifies their validity.
- **Authorization**—Grants different users different rights, and controls the users' access to resources and services. For example, you can permit office users to read and print files and prevent guests from accessing files on the device.
- **Accounting**—Records network usage details of users, including the service type, start time, and traffic. This function enables time-based and traffic-based charging and user behavior auditing.

AAA network diagram

AAA uses a client/server model. The client runs on the access device, or the network access server (NAS), which authenticates user identities and controls user access. The server maintains user information centrally. See Figure 1.

Figure 1 AAA network diagram

To access networks or resources beyond the NAS, a user sends its identity information to the NAS. The NAS transparently passes the user information to AAA servers and waits for the authentication, authorization, and accounting result. Based on the result, the NAS determines whether to permit or deny the access request.

AAA has various implementations, including RADIUS, HWTACACS, and LDAP. RADIUS is most often used.

You can use different servers to implement different security functions. For example, you can use an HWTACACS server for authentication and authorization, and use a RADIUS server for accounting.

You can choose the security functions provided by AAA as needed. For example, if your company wants employees to be authenticated before they access specific resources, you would deploy an authentication server. If network usage information is needed, you would also configure an accounting server.

The device performs dynamic password authentication.

RADIUS

Remote Authentication Dial-In User Service (RADIUS) is a distributed information interaction protocol that uses a client/server model. The protocol can protect networks against unauthorized access and is often used in network environments that require both high security and remote user access.

The RADIUS authorization process is combined with the RADIUS authentication process, and user authorization information is piggybacked in authentication responses. RADIUS uses UDP port 1812 for authentication and UDP port 1813 for accounting.

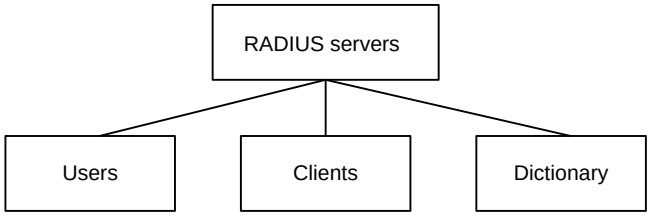
RADIUS was originally designed for dial-in user access, and has been extended to support additional access methods, such as Ethernet and ADSL.

Client/server model

The RADIUS client runs on the NASs located throughout the network. It passes user information to RADIUS servers and acts on the responses to, for example, reject or accept user access requests.

The RADIUS server runs on the computer or workstation at the network center and maintains information related to user authentication and network service access.

The RADIUS server operates using the following process:



1. Receives authentication, authorization, and accounting requests from RADIUS clients.
2. Performs user authentication, authorization, or accounting.
3. Returns user access control information (for example, rejecting or accepting the user access request) to the clients.

The RADIUS server can also act as the client of another RADIUS server to provide authentication proxy services.

The RADIUS server maintains the following databases:

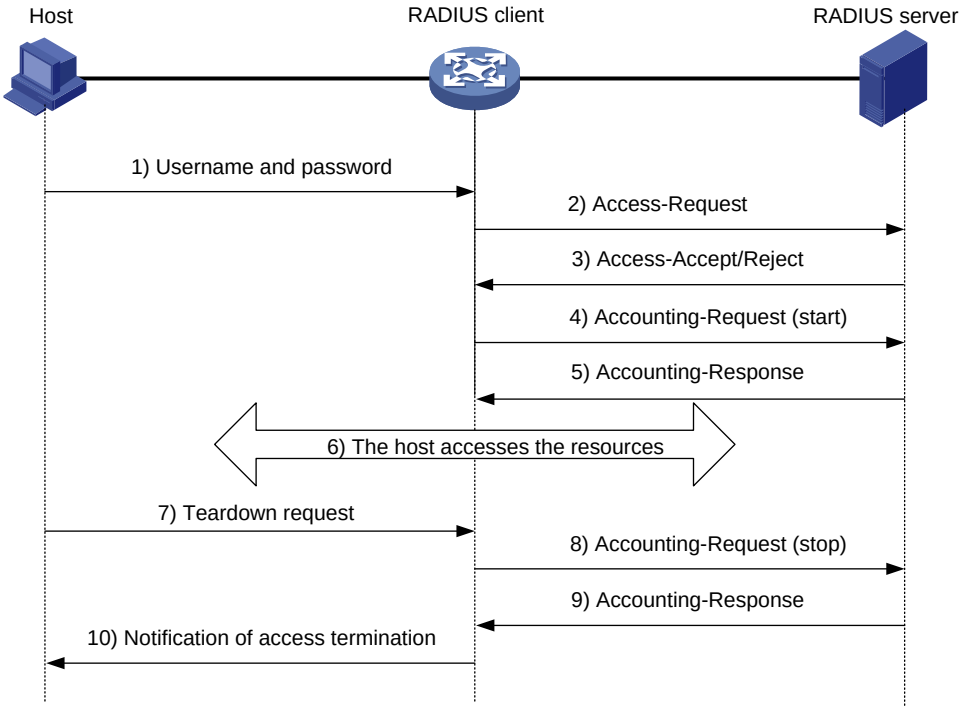
- **Users**—Stores user information, such as the usernames, passwords, applied protocols, and IP addresses.
- **Clients**—Stores information about RADIUS clients, such as shared keys and IP addresses.
- **Dictionary**—Stores RADIUS protocol attributes and their values.

Figure 2 RADIUS server databases

Information exchange security mechanism

The RADIUS client and server exchange information between them with the help of shared keys, which are preconfigured on the client and server. A RADIUS packet has a 16-byte field called Authenticator. This field includes a signature generated by using the MD5 algorithm, the shared key, and some other information. The receiver of the packet verifies the signature and accepts the packet only when the signature is correct. This mechanism ensures the security of information exchanged between the RADIUS client and server.

The shared keys are also used to encrypt user passwords that are included in RADIUS packets.



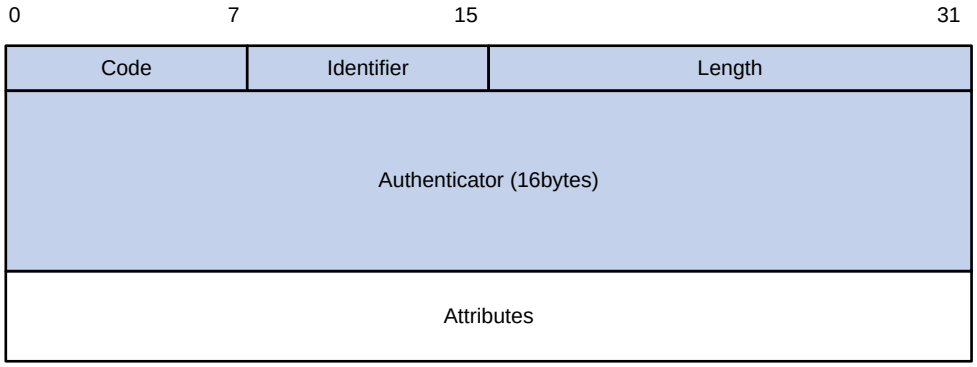
User authentication methods

The RADIUS server supports multiple user authentication methods, such as PAP, CHAP, and EAP.

Basic RADIUS packet exchange process

Figure 3 illustrates the interactions between a user host, the RADIUS client, and the RADIUS server.

Figure 3 Basic RADIUS packet exchange process



RADIUS uses in the following workflow:

1. The host sends a connection request that includes the user's username and password to the RADIUS client.
2. The RADIUS client sends an authentication request (Access-Request) to the RADIUS server. The request includes the user's password, which has been processed by the MD5 algorithm and shared key.
3. The RADIUS server authenticates the username and password. If the authentication succeeds, the server sends back an Access-Accept packet that contains the user's authorization information. If the authentication fails, the server returns an Access-Reject packet.
4. The RADIUS client permits or denies the user according to the authentication result. If the result permits the user, the RADIUS client sends a start-accounting request (Accounting-Request) packet to the RADIUS server.
5. The RADIUS server returns an acknowledgment (Accounting-Response) packet and starts accounting.
6. The user accesses the network resources.
7. The host requests the RADIUS client to tear down the connection.
8. The RADIUS client sends a stop-accounting request (Accounting-Request) packet to the RADIUS server.
9. The RADIUS server returns an acknowledgment (Accounting-Response) and stops accounting for the user.
10. The RADIUS client notifies the user of the termination.

RADIUS packet format

RADIUS uses UDP to transmit packets. The protocol also uses a series of mechanisms to ensure smooth packet exchange between the RADIUS server and the client. These mechanisms include the timer mechanism, the retransmission mechanism, and the backup server mechanism.

Figure 4 RADIUS packet format

Descriptions of the fields are as follows:

- The Code field (1 byte long) indicates the type of the RADIUS packet. Table 1 gives the main values and their meanings.

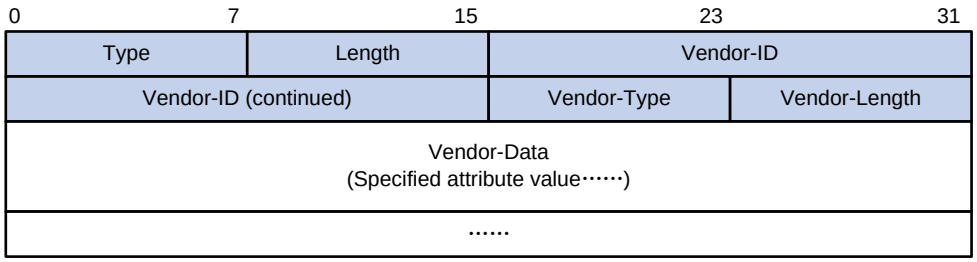
  Table 1 Main values of the Code field

Code	Packet type	Description
1	Access-Request	From the client to the server. A packet of this type includes user information for the server to authenticate the user. It must contain the User-Name attribute and can optionally contain the attributes of NAS-IP-Address, User-Password, and NAS-Port.
2	Access-Accept	From the server to the client. If all attribute values included in the Access-Request are acceptable, the authentication succeeds, and the server sends an Access-Accept response.
3	Access-Reject	From the server to the client. If any attribute value included in the Access-Request is unacceptable, the authentication fails, and the server sends an Access-Reject response.
4	Accounting-Request	From the client to the server. A packet of this type includes user information for the server to start or stop accounting for the user. The Acct-Status-Type attribute in the packet indicates whether to start or stop accounting.
5	Accounting-Response	From the server to the client. The server sends a packet of this type to notify the client that it has received the Accounting-Request and has successfully recorded the accounting information.

- The Identifier field (1 byte long) is used to match response packets with request packets and to detect duplicate request packets. The request and response packets of the same exchange process for the same purpose (such as authentication or accounting) have the same identifier.
- The Length field (2 bytes long) indicates the length of the entire packet (in bytes), including the Code, Identifier, Length, Authenticator, and Attributes fields. Bytes beyond this length are considered padding and are ignored by the receiver. If the length of a received packet is less than this length, the packet is dropped.
- The Authenticator field (16 bytes long) is used to authenticate responses from the RADIUS server and to encrypt user passwords. There are two types of authenticators: request authenticator and response authenticator.

- The Attributes field (variable in length) includes authentication, authorization, and accounting information. This field can contain multiple attributes, each with the following subfields:
  - **Type**—Type of the attribute.
  - **Length**—Length of the attribute in bytes, including the Type, Length, and Value subfields.
  - **Value**—Value of the attribute. Its format and content depend on the Type subfield.

Extended RADIUS attributes



The RADIUS protocol features excellent extensibility. The Vendor-Specific attribute (attribute 26) allows a vendor to define extended attributes. The extended attributes can implement functions that the standard RADIUS protocol does not provide.

A vendor can encapsulate multiple subattributes in the TLV format in attribute 26 to provide extended functions. As shown in Figure 5, a subattribute encapsulated in attribute 26 consists of the following parts:

- **Vendor-ID**—ID of the vendor. The most significant byte is 0. The other three bytes contains a code compliant to RFC 1700.
- **Vendor-Type**—Type of the subattribute.
- **Vendor-Length**—Length of the subattribute.
- **Vendor-Data**—Contents of the subattribute.

The device supports private RADIUS subattributes with a vendor ID of 25506. For more information, see "Appendix C RADIUS subattributes (vendor ID 25506)."

Figure 5 Format of attribute 26

HWTACACS

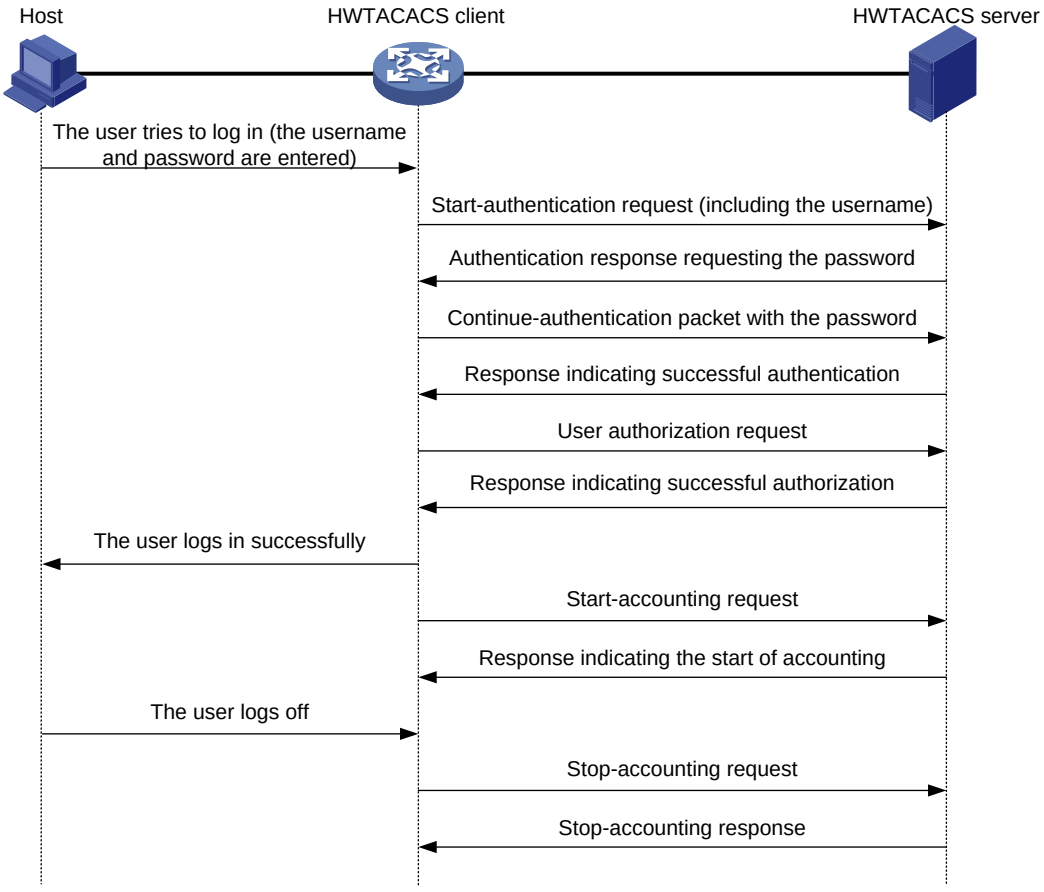
HW Terminal Access Controller Access Control System (HWTACACS) is an enhanced security protocol based on TACACS (RFC 1492). HWTACACS is similar to RADIUS, and uses a client/server model for information exchange between the NAS and the HWTACACS server.

HWTACACS typically provides AAA services for PPP, VPDN, and terminal users. In a typical HWTACACS scenario, terminal users need to log in to the NAS. Working as the HWTACACS client, the NAS sends users' usernames and passwords to the HWTACACS server for authentication. After passing authentication and obtaining authorized rights, a user logs in to the device and performs operations. The HWTACACS server records the operations that each user performs.

Differences between HWTACACS and RADIUS

HWTACACS and RADIUS have many features in common, such as using a client/server model, using shared keys for data encryption, and providing flexibility and scalability. Table 2 lists the primary differences between HWTACACS and RADIUS.

Table 2 Primary differences between HWTACACS and RADIUS



HWTACACS	RADIUS
Uses TCP, which provides reliable network	Uses UDP, which provides high transport efficiency.

HWTACACS	RADIUS
transmission.	
Encrypts the entire packet except for the HWTACACS header.	Encrypts only the user password field in an authentication packet.
Protocol packets are complicated and authorization is independent of authentication. Authentication and authorization can be deployed on different HWTACACS servers.	Protocol packets are simple and the authorization process is combined with the authentication process.
Supports authorization of configuration commands. Access to commands depends on both the user's roles and authorization. A user can use only commands that are permitted by the user roles and authorized by the HWTACACS server.	Does not support authorization of configuration commands. Access to commands solely depends on the user's roles. For more information about user roles, see *Fundamentals Configuration Guide*.

Basic HWTACACS packet exchange process

Figure 6 describes how HWTACACS performs user authentication, authorization, and accounting for a Telnet user.

Figure 6 Basic HWTACACS packet exchange process for a Telnet user

HWTACACS operates using in the following workflow:

1. A Telnet user requests to Telnet to the device and provides the username and password as instructed by the system.
2. The HWTACACS client sends a start-authentication request that includes the username to the HWTACACS server when it receives the Telnet request.

3. The HWTACACS server sends back an authentication response to request the login password.
4. Upon receipt of the response, the HWTACACS client sends the HWTACACS server a continue-authentication packet that includes the login password.
5. If the authentication succeeds, the HWTACACS server sends back an authentication response to indicate that the user has passed authentication.
6. The HWTACACS client sends a user authorization request packet to the HWTACACS server.
7. If the authorization succeeds, the HWTACACS server sends back an authorization response, indicating that the user is now authorized.
8. Knowing that the user is now authorized, the HWTACACS client pushes its CLI to the user and permits the user to log in.
9. The HWTACACS client sends a start-accounting request to the HWTACACS server.
10. The HWTACACS server sends back an accounting response, indicating that it has received the start-accounting request.
11. The user logs off.
12. The HWTACACS client sends a stop-accounting request to the HWTACACS server.
13. The HWTACACS server sends back a stop-accounting response, indicating that the stop-accounting request has been received.

LDAP

The Lightweight Directory Access Protocol (LDAP) provides standard multiplatform directory service. LDAP was developed on the basis of the X.500 protocol. It improves the following functions of X.500:

- Read/write interactive access.
- Browse.
- Search.

LDAP is suitable for storing data that does not often change. The protocol is used to store user information. For example, LDAP server software Active Directory Server is used in Microsoft Windows operating systems. The software stores the user information and user group information for user login authentication and authorization.

LDAP directory service

LDAP uses directories to maintain the organization information, personnel information, and resource information. The directories are organized in a tree structure and include entries. An entry is a set of attributes with distinguished names (DNs). The attributes are used to store information such as usernames, passwords, emails, computer names, and phone numbers.

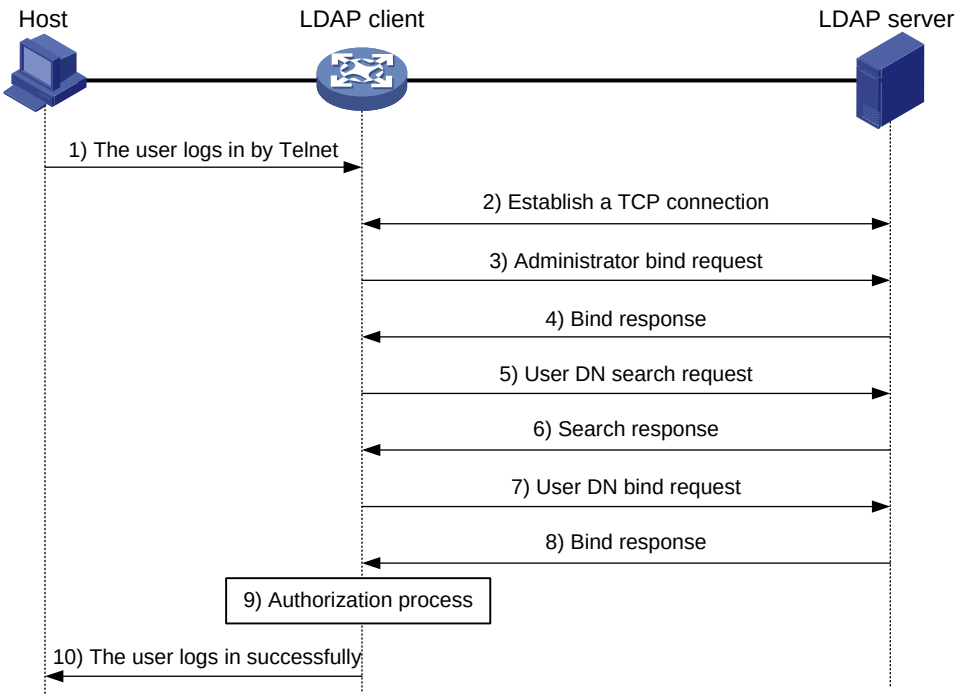
LDAP uses a client/server model, and all directory information is stored in the LDAP server. Commonly used LDAP server products include Microsoft Active Directory Server, IBM Tivoli Directory Server, and Sun ONE Directory Server.

LDAP authentication and authorization

AAA can use LDAP to provide authentication and authorization services for users. LDAP defines a set of operations to implement its functions. The main operations for authentication and authorization are the bind operation and search operation.

- The bind operation allows an LDAP client to perform the following operations:
  - Establish a connection with the LDAP server.
  - Obtain the access rights to the LDAP server.
  - Check the validity of user information.
- The search operation constructs search conditions and obtains the directory resource information of the LDAP server.

In LDAP authentication, the client completes the following tasks:



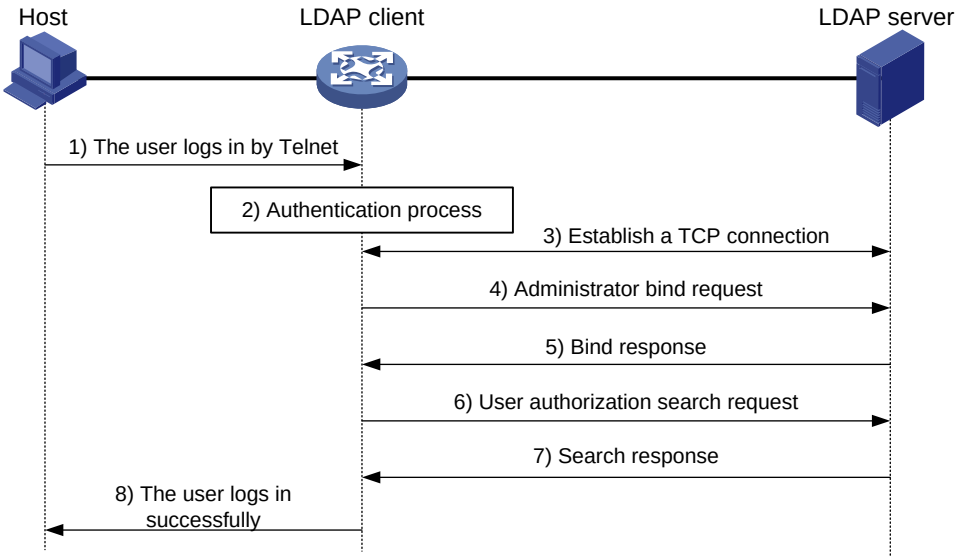
1. Uses the LDAP server administrator DN to bind with the LDAP server. After the binding is created, the client establishes a connection to the server and obtains the right to search.
2. Constructs search conditions by using the username in the authentication information of a user. The specified root directory of the server is searched and a user DN list is generated.
3. Binds with the LDAP server by using each user DN and password. If a binding is created, the user is considered legal.

In LDAP authorization, the client performs the same tasks as in LDAP authentication. When the client constructs search conditions, it obtains both authorization information and the user DN list.

Basic LDAP authentication process

The following example illustrates the basic LDAP authentication process for a Telnet user.

Figure 7 Basic LDAP authentication process for a Telnet user



The following shows the basic LDAP authentication process:

1. A Telnet user initiates a connection request and sends the username and password to the LDAP client.
2. After receiving the request, the LDAP client establishes a TCP connection with the LDAP server.
3. To obtain the right to search, the LDAP client uses the administrator DN and password to send an administrator bind request to the LDAP server.
4. The LDAP server processes the request. If the bind operation is successful, the LDAP server sends an acknowledgment to the LDAP client.
5. The LDAP client sends a user DN search request with the username of the Telnet user to the LDAP server.
6. After receiving the request, the LDAP server searches for the user DN by the base DN, search scope, and filtering conditions. If a match is found, the LDAP server sends a response to notify the LDAP client of the successful search. There might be one or more user DNs found.
7. The LDAP client uses the obtained user DN and the entered user password as parameters to send a user DN bind request to the LDAP server. The server will check whether the user password is correct.

8. The LDAP server processes the request, and sends a response to notify the LDAP client of the bind operation result. If the bind operation fails, the LDAP client uses another obtained user DN as the parameter to send a user DN bind request to the LDAP server. This process continues until a DN is bound successfully or all DNs fail to be bound. If all user DNs fail to be bound, the LDAP client notifies the user of the login failure and denies the user's access request.
9. The LDAP client saves the user DN that has been bound and exchanges authorization packets with the authorization server.
   - If LDAP authorization is used, see the authorization process shown in Figure 8.
   - If another method is expected for authorization, the authorization process of that method applies.
10. After successful authorization, the LDAP client notifies the user of the successful login.

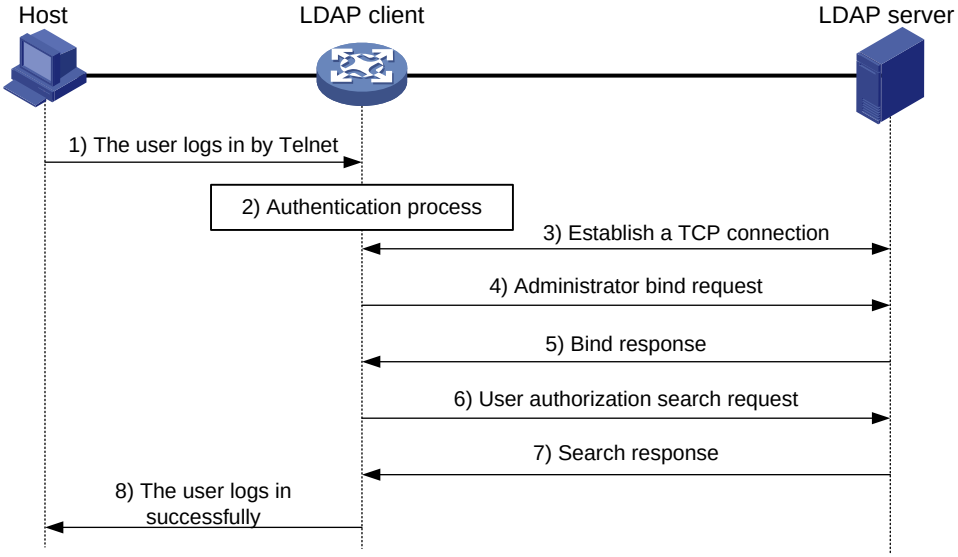


Figure 8 Basic LDAP authorization process for a Telnet user

Basic LDAP authorization process

The following example illustrates the basic LDAP authorization process for a Telnet user.

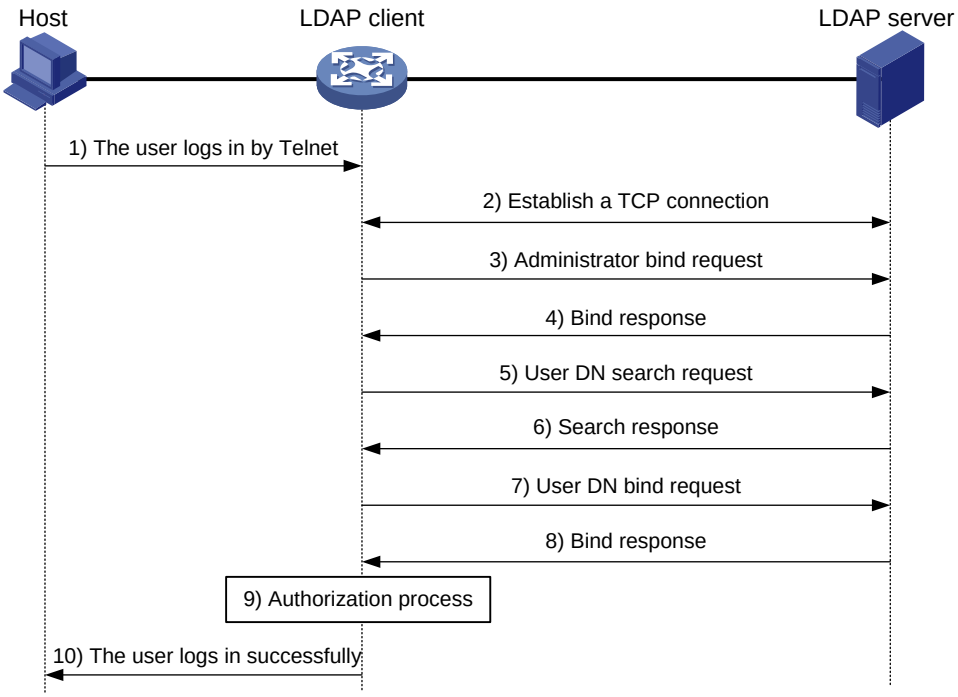

Figure 9 Basic LDAP authorization process for a Telnet user

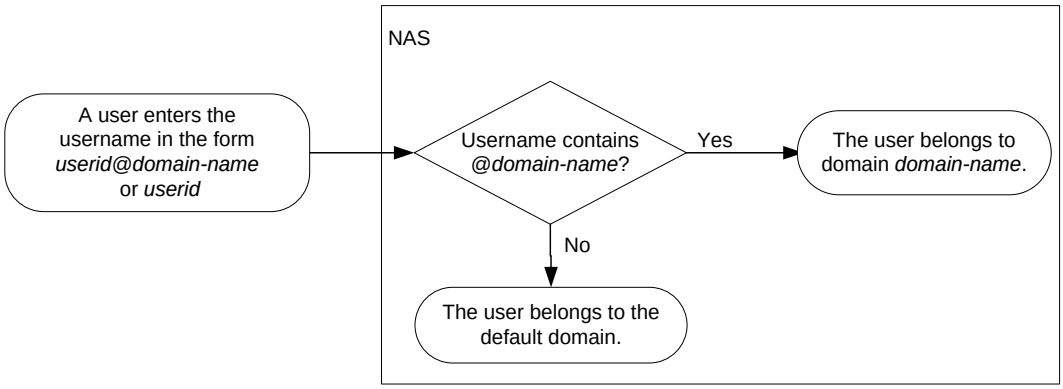
The following shows the basic LDAP authorization process:

1. A Telnet user initiates a connection request and sends the username and password to the device. The device will act as the LDAP client during authorization.
2. After receiving the request, the device exchanges authentication packets with the authentication server for the user:
   - If LDAP authentication is used, see the authentication process shown in Figure 10.
     - If the device (the LDAP client) uses the same LDAP server for authentication and authorization, skip to step 6.
     - If the device (the LDAP client) uses different LDAP servers for authentication and authorization, skip to step 4.
   - If another authentication method is used, the authentication process of that method applies. The device acts as the LDAP client. Skip to step 3.
3. The LDAP client establishes a TCP connection with the LDAP authorization server.
4. To obtain the right to search, the LDAP client uses the administrator DN and password to send an administrator bind request to the LDAP server.
5. The LDAP server processes the request. If the bind operation is successful, the LDAP server sends an acknowledgment to the LDAP client.
6. The LDAP client sends an authorization search request with the username of the Telnet user to the LDAP server. If the user uses the same LDAP server for authentication and authorization, the client sends the request with the saved user DN of the Telnet user to the LDAP server.
7. After receiving the request, the LDAP server searches for the user information by the base DN, search scope, filtering conditions, and LDAP attributes. If a match is found, the LDAP server sends a response to notify the LDAP client of the successful search.
8. After successful authorization, the LDAP client notifies the user of the successful login.

Figure 10 Basic LDAP authentication process for a Telnet user



User management based on ISP domains and user access types

AAA manages users based on the users' ISP domains and access types.

On a NAS, each user belongs to one ISP domain. The NAS determines the ISP domain to which a user belongs based on the username entered by the user at login.

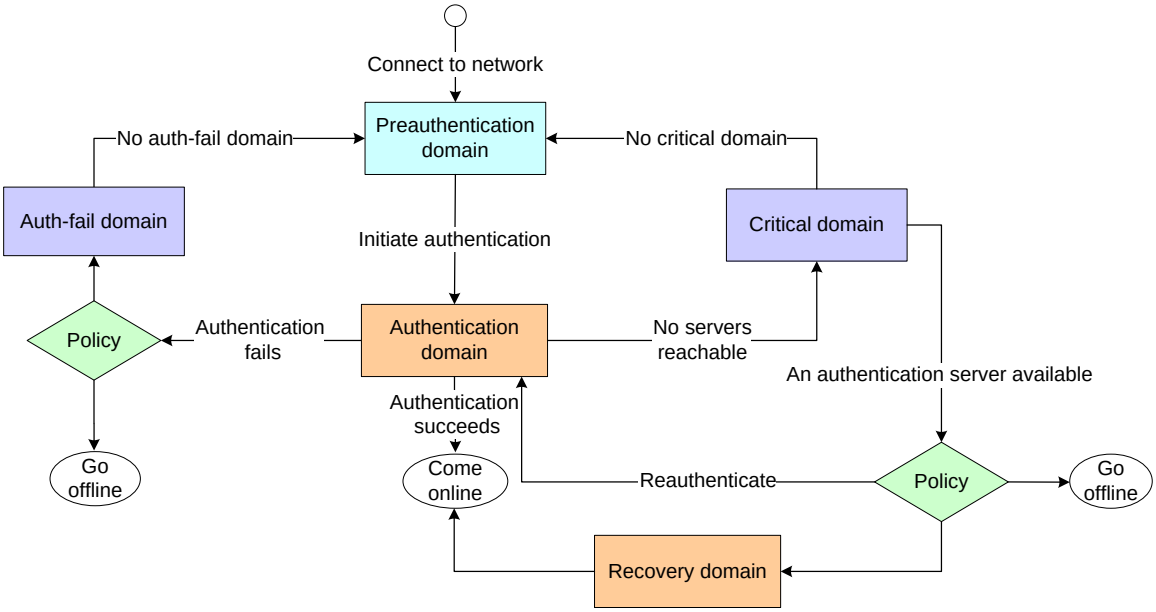
Figure 11 Determining the ISP domain for a user by username

AAA manages users in the same ISP domain based on the users' access types. The device supports the following user access types:

- **LAN**—LAN users must pass 802.1X or MAC authentication to come online.
- **Login**—Login users include SSH, Telnet, FTP, and terminal users that log in to the device. Terminal users can access through a console port.
- **Portal**—Portal users must pass portal authentication to access the network.
- **HTTP/HTTPS**—Users log in to the device through HTTP or HTTPS.

The device also provides authentication modules (such as 802.1X) for implementation of user authentication management policies. If you configure these authentication modules, the ISP domains for users of the access types depend on the configuration of the authentication modules.

The device provides the following types of ISP domains for you to control access of wired 802.1, Web authentication, and MAC authentication users to network resources at different phases of authentication:



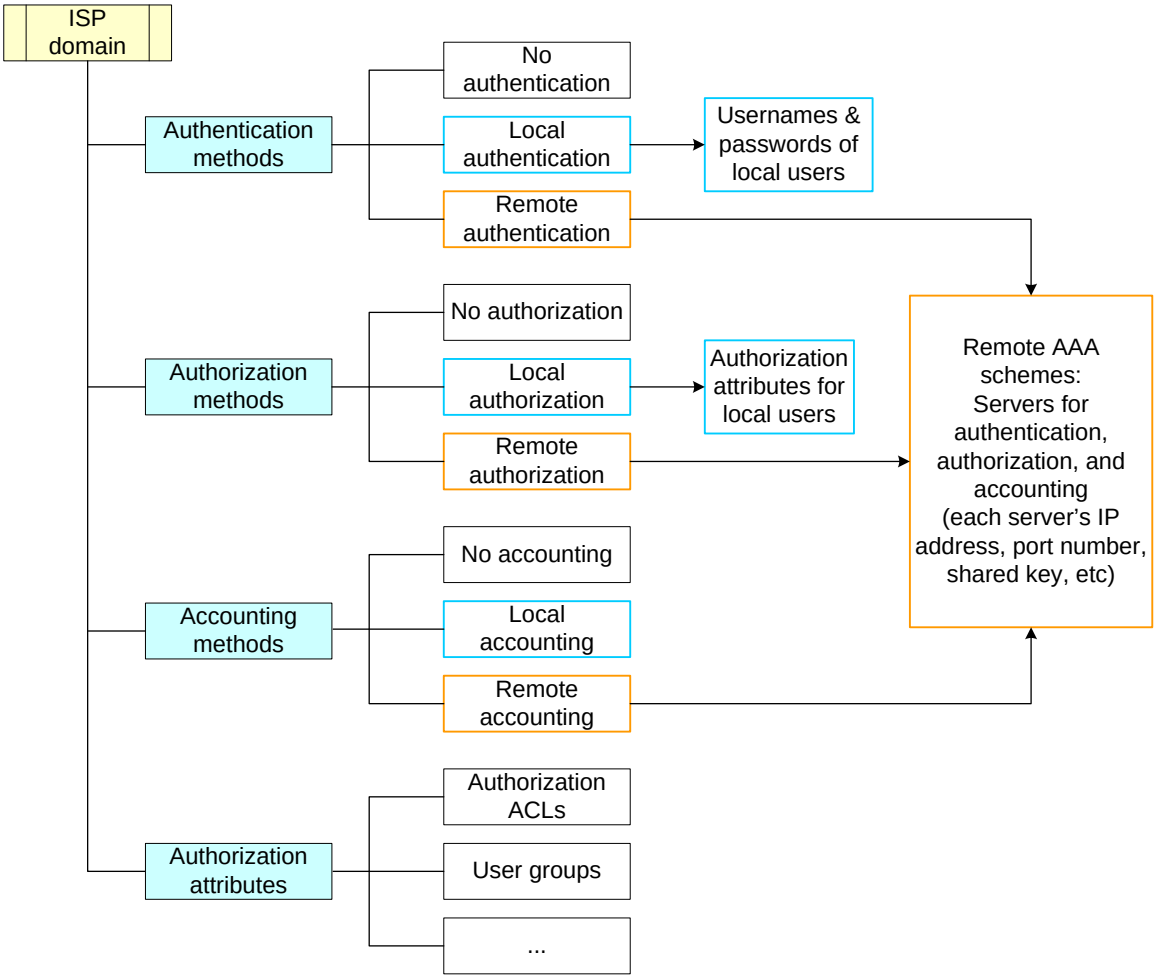
- **Preauthentication domain**—The domain to which users belong before authentication starts for them. For example, users are placed in the preauthentication domain in the following situations:
  - Before they authenticate to the network for the first time.
  - When they fail authentication in an ISP domain that does not have an auth-fail domain.
  - When no authentication servers are available, they are assigned to the specified critical domain. However, the specified critical domain does not exist.

  The preauthentication domain is applicable only to 802.1X and Web authentication users.
- **Authentication domain**—The ISP domain in which users are authenticated and come online.
- **Auth-fail domain**—The ISP domain specified to accommodate users that have failed authentication in an authentication domain.
- **Critical domain**—The ISP domain specified to accommodate users that access an authentication domain when all RADIUS servers in that authentication domain are unavailable.
- **Recovery domain**—The ISP domain to which users in the critical domain are moved after a RADIUS authentication server in their authentication domain becomes available.

IMPORTANT:

In the current version, you must specify the authentication domain as the recovery domain.

Figure 12 Movement of users between different types of ISP domains



Authentication, authorization, and accounting methods

As shown in Figure 13, an ISP domain represents a set of authentication, authorization, and accounting methods for different types of users in an ISP domain. The NAS determines the ISP domain and access type of a user. The NAS also uses the methods configured for the access type in the domain to control the user's access.

AAA also supports configuring a set of default methods for an ISP domain. These default methods are applied to users for whom no AAA methods are configured.

Figure 13 AAA configuration structure for an ISP domain

Authentication methods

The device supports the following authentication methods:

- **No authentication**—This method trusts all users and does not perform authentication. For security purposes, do not use this method.
- **Local authentication**—The NAS authenticates users by itself, based on the locally configured user information including the usernames, passwords, and attributes. Local authentication allows high speed and low cost, but the amount of information that can be stored is limited by the size of the storage space.
- **Remote authentication**—The NAS works with a remote server to authenticate users. The NAS communicates with the remote server through the RADIUS, HWTACACS, or LDAP protocol. The server manages user information in a centralized manner. Remote authentication provides high capacity, reliable, and centralized authentication services for multiple NASs. You can configure backup methods to be used when the remote server is not available.

Authorization methods

The device supports the following authorization methods:

- **No authorization**—The NAS performs no authorization exchange. The following default authorization information applies after users pass authentication:
  - Login users obtain the level-0 user role. For more information about the level-0 user role, see RBAC configuration in *Fundamentals Configuration Guide*.

    - The working directory for FTP, SFTP, and SCP login users is the root directory of the NAS. However, the users do not have permission to access the root directory.
    - Non-login users can access the network.
- **Local authorization**—The NAS performs authorization according to the user attributes locally configured for users.
- **Remote authorization**—The NAS works with a remote server to authorize users. RADIUS authorization is bound with RADIUS authentication. RADIUS authorization can work only after RADIUS authentication is successful, and the authorization information is included in the Access-Accept packet. HWTACACS or LDAP authorization is separate from authentication, and the authorization information is included in the authorization response after successful authentication. You can configure backup methods to be used when the remote server is not available.

Accounting methods

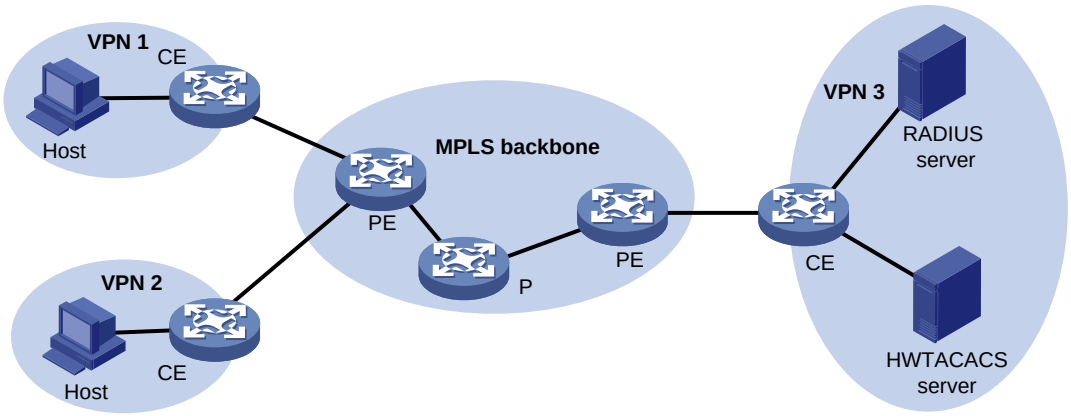
The device supports the following accounting methods:

- **No accounting**—The NAS does not perform accounting for the users.
- **Local accounting**—Local accounting is implemented on the NAS. It counts and controls the number of concurrent users that use the same local user account, but does not provide statistics for charging.
- **Remote accounting**—The NAS works with a RADIUS server or HWTACACS server for accounting. You can configure backup methods to be used when the remote server is not available.

Authorization attribute configuration methods

You can configure authorization attributes for an ISP domain on the NAS, on a server, or on both the NAS and a server. Server-assigned authorization attributes have higher priority than NAS-assigned settings. NAS-assigned attributes can take effect only if they do not conflict with server-assigned attributes. If a NAS-assigned attribute conflicts with a server-assigned attribute, the server-assigned attribute takes effect.

AAA extended functions



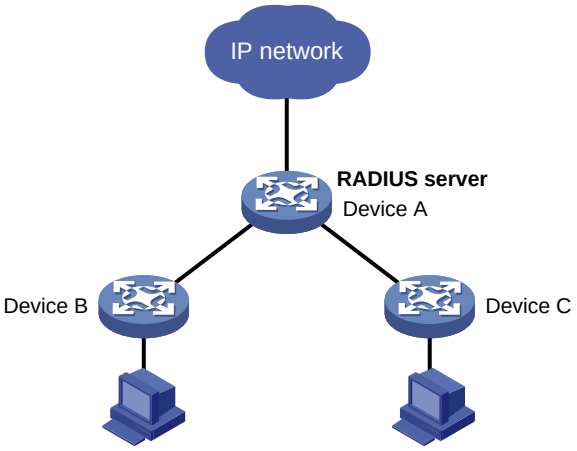
The device provides the following login services to enhance device security:

- **Command authorization**—Enables the NAS to let the authorization server determine whether a command entered by a login user is permitted. Login users can execute only commands permitted by the authorization server. For more information about command authorization, see *Fundamentals Configuration Guide*.
- **Command accounting**—When command authorization is disabled, command accounting enables the accounting server to record all valid commands executed on the device. When command authorization is enabled, command accounting enables the accounting server to record all authorized commands. For more information about command accounting, see *Fundamentals Configuration Guide*.
- **User role authentication**—Authenticates each user that wants to obtain another user role without logging out or getting disconnected. For more information about user role authentication, see *Fundamentals Configuration Guide*.

AAA for VPNs

You can deploy AAA across VPNs to enable forwarding of authentication, authorization, and accounting packets across VPNs. For example, as shown in Figure 14, the PE at the left side of the MPLS backbone acts as a NAS. The NAS transparently delivers the AAA packets of private users in VPN 1 and VPN 2 to the AAA servers in VPN 3 for centralized authentication. Authentication packets of private users in different VPNs do not affect each other.

Figure 14 Network diagram



This feature can also help an MCE to implement portal authentication for VPNs. For more information about MCE, see *MCE Configuration Guide*. For more information about portal authentication, see "Configuring portal authentication."

RADIUS server feature of the device

Enable the RADIUS server feature of the device to work with RADIUS clients for user authentication and authorization. The device can act as a dedicated RADIUS server or as both a RADIUS server and a RADIUS client at the same time.

The RADIUS server feature provides for flexible networks with less cost. As shown in Figure 15, Device A provides RADIUS server functions at the distribution layer; Device B and Device C are configured with RADIUS schemes to implement user authentication and authorization at the access layer.

Figure 15 Network diagram

The RADIUS server feature supports the following operations:

- Manages RADIUS user data, which is generated from local user information and includes user name, password, description, authorization ACL, authorization VLAN, and expiration time.
- Manages RADIUS clients. You can add, modify, and delete RADIUS clients. A RADIUS client is identified by the IP address, and it includes attribute information such as the shared key. The RADIUS server feature processes authentication requests only from the managed RADIUS clients and ignores requests from unknown clients.

- Authenticates and authorizes users of the network access type. The server does not provide accounting.

When the RADIUS server receives a RADIUS packet, it performs the following actions:

1. Verifies that the packet is sent from a managed RADIUS client.
2. Verifies the packet with the shared key.
3. Verifies that the user account exists, the password is correct, and other attributes meet the requirements (for example, the account is in the validity period).
4. Determines the authentication result and authorizes specific privileges to the authenticated user.

The RADIUS server feature of the device has the following restrictions:

- The authentication port is fixed at UDP 1812 and cannot be modified.
- The feature is supported on IPv4 networks, but not on IPv6 networks.
- The server provides only PAP and CHAP authentication methods.
- User names sent to the RADIUS server cannot include a domain name.

Protocols and standards

- RFC 2865, *Remote Authentication Dial In User Service (RADIUS)*
- RFC 2866, *RADIUS Accounting*
- RFC 2867, *RADIUS Accounting Modifications for Tunnel Protocol Support*
- RFC 2868, *RADIUS Attributes for Tunnel Protocol Support*
- RFC 2869, *RADIUS Extensions*
- RFC 3576, *Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)*
- RFC 4818, *RADIUS Delegated-IPv6-Prefix Attribute*
- RFC 5176, *Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)*
- RFC 1492, *An Access Control Protocol, Sometimes Called TACACS*
- RFC 1777, *Lightweight Directory Access Protocol*
- RFC 2251, *Lightweight Directory Access Protocol (v3)*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

AAA tasks at a glance

To configure AAA, perform the following tasks:

1. Configuring AAA schemes

   If local authentication is used, configure local users and the related attributes. If remote authentication is used, configure the required RADIUS, HWTACACS, or LDAP schemes.

   - Configuring local users
   - Configuring RADIUS

- Configuring HWTACACS
- Configuring LDAP

2. Configuring an ISP domain
   a. Creating an ISP domain
   b. Configuring ISP domain attributes
3. Configuring AAA methods for an ISP domain

   Configure authentication, authorization, and accounting methods for an ISP domain as needed. These methods use existing AAA schemes.
   - Configuring authentication methods for an ISP domain
   - Configuring authorization methods for an ISP domain
   - Configuring accounting methods for an ISP domain
4. (Optional.) Configuring advanced AAA features
   - Configuring AAA fail-permit and recovery
   - Setting the maximum number of concurrent login users
   - Configuring a NAS-ID
   - Configuring the device ID
   - Enabling password change prompt logging
   - Configuring the RADIUS server feature
   - Configuring the connection recording policy
   - Displaying user MAC and UUID binding entries
   - Configuring the AAA test feature
   - Configuring authorization information cache for AAA users

Configuring local users

About local users

To implement local authentication, authorization, and accounting, create local users and configure user attributes on the device. The local users and attributes are stored in the local user database on the device. A local user is uniquely identified by the combination of a username and a user type.

Local users are classified into the following types:

- **Device management user**—User that logs in to the device for device management.
- **Network access user**—User that accesses network resources through the device.

  Network access users also include guests that access the network temporarily. Guests can use only LAN and portal services.

The following shows the configurable local user attributes:

- **Description**—Descriptive information of the user.
- **Service type**—Services that the user can use. Local authentication checks the service types of a local user. If none of the service types is available, the user cannot pass authentication.
- **User state**—Whether or not a local user can request network services. There are two user states: active and blocked. A user in active state can request network services, but a user in blocked state cannot.
- **Upper limit of concurrent logins using the same user name**—Maximum number of users that can concurrently access the device by using the same user name. When the number reaches the upper limit, no more local users can access the device by using the user name.

- **User group**—Each local user belongs to a local user group and has all attributes of the group. The attributes include the password control attributes and authorization attributes. For more information about local user group, see "Configuring user group attributes."
- **Binding attributes**—Binding attributes control the scope of users, and are checked during local authentication of a user. If the attributes of a user do not match the binding attributes configured for the local user account, the user cannot pass authentication.
- **Authorization attributes**—Authorization attributes indicate the user's rights after it passes local authentication.

  Configure the authorization attributes based on the service type of local users.

  You can configure an authorization attribute in user group view or local user view. The setting of an authorization attribute in local user view takes precedence over the attribute setting in user group view.

  The attribute configured in user group view takes effect on all local users in the user group.

  The attribute configured in local user view takes effect only on the local user.
- **Password control attributes**—Password control attributes help control password security for local users. Password control attributes include password aging time, minimum password length, password composition checking, password complexity checking, and login attempt limit.

  You can configure a password control attribute in system view, user group view, or local user view. A password control attribute with a smaller effective range has a higher priority. For more information about password management and global password configuration, see "Configuring password control."
- **Validity period**—Time period in which a network access user is considered valid for authentication.

Local user configuration tasks at a glance

To configure local users, perform the following tasks:

1. Configuring local user attributes
   - Configuring attributes for device management users
   - Configuring attributes for network access users
   - Configuring local guest attributes
2. (Optional.) Configuring user group attributes
3. (Optional.) Managing local guests
4. (Optional.) Configuring the local user auto-delete feature
5. (Optional.) Configuring SNMP notifications for local users

Configuring attributes for device management users

Restrictions and guidelines

When you configure the interface binding attribute for a device management user, follow these restrictions and guidelines to avoid authentication failure:

- Specify the actual access interface of the user as the binding interface for the user.
- Make sure the user's authentication packets include the user's access interface.

If password control is globally enabled for device management users by using the **`password-control enable`** command, the device neither displays local user passwords nor retains them in the running configuration. When you globally disable password control for device management users, local user passwords are automatically restored to the running configuration. To display the running configuration, use the **`display current-configuration`** command.

You can configure authorization attributes and password control attributes in local user view or user group view. The setting in local user view takes precedence over the setting in user group view.

Procedure

1. Enter system view.

   system-view

2. Add a device management user and enter device management user view.

   local-user *user-name* **class manage**

3. Configure a password for the device management user.

   In non-FIPS mode:

   password [{ **hash** | **simple** } *string*]

   A non-password-protected user passes authentication if the user provides the correct username and passes attribute checks. To enhance security, configure a password for each device management user.

   In FIPS mode:

   password

   Only password-protected users can pass authentication. You must set the password in interactive mode for a device management user.

4. Assign services to the device management user.

   In non-FIPS mode:

   service-type { **ftp** | { **http** | **https** | **ssh** | **telnet** | **terminal** } * }

   In FIPS mode:

   service-type { **https** | **ssh** | **terminal** } *

   By default, no services are authorized to a device management user.

5. (Optional.) Set the status of the device management user.

   state { **active** | **block** }

   By default, a device management user is in active state and can request network services.

6. (Optional.) Set the upper limit of concurrent logins using the device management username.

   access-limit *max-user-number*

   By default, the number of concurrent logins is not limited for a device management user.

   This command takes effect only when local accounting is configured for device management users. This command does not apply to FTP, SFTP, or SCP users that do not support accounting.

7. (Optional.) Configure the interface binding attribute for the device management user.

   bind-attribute location interface *interface-type interface-number*

   By default, no interface binding attribute is configured for a device management user.

8. (Optional.) Configure authorization attributes for the device management user.

   authorization-attribute { **idle-cut** *minutes* | **user-role** *role-name* | **work-directory** *directory-name* } *

   The following default settings apply:

   - The working directory for FTP, SFTP, and SCP users is the root directory of the NAS. However, the users do not have permission to access the root directory.
   - The network-operator user role is assigned to the device management local users that are created by a network-admin, system-admin, or level-15 user.

9. (Optional.) Configure password control attributes for the device management user. Choose the following tasks as needed:

   - Set the password aging time.

password-control aging *aging-time*

- Set the minimum password length.
  password-control length *length*
- Configure the password composition policy.
  password-control composition type-number *type-number* [**type-length** *type-length*]
- Configure the password complexity checking policy.
  password-control complexity { **same-character** | **user-name** } **check**
- Configure the maximum login attempts and the action to take if there is a login failure.
  password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

By default, a device management user uses password control attributes of the user group to which the user belongs.

10. (Optional.) Assign the device management user to a user group.
group *group-name*
By default, a device management user belongs to user group **system**.

Configuring attributes for network access users

Restrictions and guidelines

If password control is globally enabled for network access users by using the **password-control enable network-class** command, the device neither displays local user passwords nor retains them in the running configuration. When you globally disable password control for network access users, local user passwords are automatically restored to the running configuration. To display the running configuration, use the **display current-configuration** command.

You can configure authorization attributes and password control attributes in local user view or user group view. The setting in local user view takes precedence over the setting in user group view.

Configure the **location** binding attribute based on the service types of users.

- For 802.1X users, specify the 802.1X-enabled Layer 2 Ethernet interfaces or Layer 2 aggregate interfaces through which the users access the device.
- For MAC authentication users, specify the MAC authentication-enabled Layer 2 Ethernet interfaces or Layer 2 aggregate interfaces through which the users access the device.
- For Web authentication users, specify the Web authentication-enabled Layer 2 Ethernet interfaces through which the users access the device.
- For portal users, specify the portal-enabled interfaces through which the users access the device. Specify the Layer 2 Ethernet interfaces if portal is enabled on VLAN interfaces and the **portal roaming enable** command is not used.

Procedure

1. Enter system view.
system-view

2. Add a network access user and enter network access user view.
local-user *user-name* **class network**

3. (Optional.) Configure a password for the network access user.
password { **cipher** | **simple** } *string*

4. (Optional.) Configure a description for the network access user.
description *text*

By default, no description is configured for a local user.

5. Assign services to the network access user.

   service-type { **lan-access** | **portal** }

   By default, no services are authorized to a network access user.

6. (Optional.) Set the status of the network access user.

   state { **active** | **block** }

   By default, a network access user is in active state and can request network services.

7. (Optional.) Set the upper limit of concurrent logins using the network access username.

   access-limit *max-user-number*

   By default, the number of concurrent logins is not limited for a network access user.

8. (Optional.) Configure binding attributes for the network access user.

   bind-attribute { **ip** *ip-address* | **location interface** *interface-type interface-number* | **mac** *mac-address* | **vlan** *vlan-id* } *

   By default, no binding attributes are configured for a network access user.

9. (Optional.) Configure authorization attributes for the network access user.

   authorization-attribute { **acl** *acl-number* | **idle-cut** *minutes* | **ip-pool** *ipv4-pool-name* | **ipv6-pool** *ipv6-pool-name* | **session-timeout** *minutes* | **url** *url-string* | **vlan** *vlan-id* } *

   By default, a network access user does not have authorization attributes.

10. (Optional.) Configure password control attributes for the network access user. Choose the following tasks as needed:

    - Set the minimum password length.

      password-control length *length*

    - Configure the password composition policy.

      password-control composition type-number *type-number* [**type-length** *type-length*]

    - Configure the password complexity checking policy.

      password-control complexity { **same-character** | **user-name** } **check**

    By default, a network access user uses password control attributes of the user group to which the user belongs.

11. (Optional.) Assign the network access user to a user group.

    group *group-name*

    By default, a network access user belongs to user group **system**.

12. (Optional.) specify the validity period for the local user.

    validity-datetime { **from** *start-date start-time* **to** *expiration-date expiration-time* | **from** *start-date start-time* | **to** *expiration-date expiration-time* }

    By default, the validity period for a network access user does not expire.

Configuring local guest attributes

About this task

Create local guests and configure guest attributes to control temporary network access behavior. Guests can access the network after passing local authentication. You can configure the recipient addresses and email attribute information to the local guests and guest sponsors.

Procedure

1. Enter system view.
   system-view
2. Create a local guest and enter local guest view.
   local-user *user-name* **class network guest**
3. (Optional.) Configure a password for the local guest.
   password { **cipher** | **simple** } *string*
4. Configure basic information for the local guest. Choose the following tasks as needed:
   - Configure a description for the local guest.
     description *text*
     By default, no description is configured for a local guest.
   - Specify the name of the local guest.
     full-name *name-string*
     By default, no name is specified for a local guest.
   - Specify the company of the local guest.
     company *company-name*
     By default, no company is specified for a local guest.
   - Specify the phone number of the local guest.
     phone *phone-number*
     By default, no phone number is specified for a local guest.
   - Specify the email address of the local guest.
     email *email-string*
     By default, no email address is specified for a local guest.
   - Specify the sponsor name for the local guest.
     sponsor-full-name *name-string*
     By default, no sponsor name is specified for a local guest.
   - Specify the sponsor department for the local guest.
     sponsor-department *department-string*
     By default, no sponsor department is specified for a local guest.
   - Specify the sponsor email address for the local guest.
     sponsor-email *email-string*
     By default, no sponsor email address is specified for a local guest.
5. (Optional.) Configure the validity period for the local guest.
   validity-datetime from *start-date start-time* **to** *expiration-date expiration-time*
   By default, a local guest does not expire.
6. (Optional.) Assign the local guest to a user group.
   group *group-name*
   By default, a local guest belongs to the system-defined user group **system**.
7. (Optional.) Configure the local guest status.
   state { **active** | **block** }
   By default, a local guest is in active state and is allowed to request network services.

Configuring user group attributes

About this task

User groups simplify local user configuration and management. A user group contains a group of local users and has a set of local user attributes. You can configure local user attributes for a user group to implement centralized user attributes management for the local users in the group. Local user attributes that are manageable include authorization attributes.

Procedure

1. Enter system view.

   system-view

2. Create a user group and enter user group view.

   user-group *group-name*

   By default, a system-defined user group exists. The group name is **system**.

3. Configure authorization attributes for the user group.

   authorization-attribute { **acl** *acl-number* | **idle-cut** *minutes* | **ip-pool** *ipv4-pool-name* | **ipv6-pool** *ipv6-pool-name* | **session-timeout** *minutes* | **url** *url-string* | **vlan** *vlan-id* | **work-directory** *directory-name* } *

   By default, no authorization attributes are configured for a user group.

4. (Optional.) Configure password control attributes for the user group. Choose the following tasks as needed:

   - Set the password aging time.

     password-control aging *aging-time*

   - Set the minimum password length.

     password-control length *length*

   - Configure the password composition policy.

     password-control composition type-number *type-number* [**type-length** *type-length*]

   - Configure the password complexity checking policy.

     password-control complexity { **same-character** | **user-name** } **check**

   - Configure the maximum login attempts and the action to take for login failures.

     password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

   By default, a user group uses the global password control settings. For more information, see "Configuring password control."

Managing local guests

About this task

The local guest management features are for registration, approval, maintenance, and access control of local guests.

The device provides the following local guest management features:

- **Registration and approval**—The device creates local guests after the guest registration information is approved by a guest manager.

  The registration and approval processes are as follows:

  a. The device pushes the portal user registration page to a user that wants to access the network as a local guest.

b. The user submits account information for registration, including the user name, password, and email address.

c. The device forwards the registration request to the guest manager in an email notification.

d. The guest manager adds supplementary information as needed and approves the registration information.

The guest manager must process the registration request before the waiting-approval timeout timer expires. The device automatically deletes expired registration request information.

e. The device creates a local guest account and sends an email notification to the user and guest sponsor. The email contains local guest account, password, validity period, and other account information.

The user can access the network as a local guest.

- **Email notification**—The device notifies the local guests, guest sponsors, or guest managers by email of the guest account information or guest registration requests.
- **Local guest creation in batch**—Create a batch of local guests.
- **Local guest import**—Import guest account information from a .csv file to create local guests on the device based on the imported information.
- **Local guest export**—Export local guest account information to a .csv file. You can import the account information to other devices as needed.

Procedure

1. Enter system view

system-view

2. Configure the email notification feature for local guests.

a. Configure the subject and body of email notifications.

local-guest email format to { **guest** | **manager** | **sponsor** } { **body** *body-string* | **subject** *sub-string* }

By default, no subject or body is configured.

b. Configure the email sender address in the email notifications sent by the device for local guests.

local-guest email sender *email-address*

By default, no email sender address is configured for the email notifications sent by the device.

c. Specify an SMTP server for sending email notifications of local guests.

local-guest email smtp-server *url-string*

By default, no SMTP server is specified.

3. Configure the guest manager's email address.

local-guest manager-email *email-address*

By default, the guest manager's email address is not configured.

4. (Optional.) Set the waiting-approval timeout timer for guest registration requests.

local-guest timer waiting-approval *time-value*

By default, the waiting-approval timeout timer for guest registration requests is 24 hours.

5. (Optional.) Create local guests in batch.

local-guest generate username-prefix *name-prefix* [**password-prefix** *password-prefix*] **suffix** *suffix-number* [**group** *group-name*] **count** *user-count* **validity-datetime** *start-date start-time* **to** *expiration-date expiration-time*

Batch generated local guests share the same name prefix. You can also configure a password prefix to be shared by the guests.

6. (Optional.) Import guest account information from a .csv file in the specified path to create local guests based on the imported information.

   local-user-import class network guest url *url-string* **validity-datetime** *start-date start-time* **to** *expiration-date expiration-time* [**auto-create-group** | **override** | **start-line** *line-number*] *

7. (Optional.) Export local guest account information to a .csv file in the specified path.

   local-user-export class network guest url *url-string*

8. (Optional.) Send email notifications to the local guest or the guest sponsor.

   a. Return to user view.

      quit

   b. Send email notifications to the local guest or the guest sponsor. The email contents include the user name, password, and validity period of the guest account.

      local-guest send-email user-name *user-name* **to** { **guest** | **sponsor** }

Configuring the local user auto-delete feature

About this task

This feature enables the device to examine the validity of local users at fixed time periods of 10 minutes and automatically delete expired local users.

Procedure

1. Enter system view

   system-view

2. Enable the local user auto-delete feature.

   local-user auto-delete enable

   By default, the local user auto-delete feature is disabled.

Configuring SNMP notifications for local users

About this task

With SNMP notifications enabled for password changes of local users, the system generates alarms when one of the following cases occurs:

- The password of a local user is configured or changed from the CLI.
- The password of a local user is changed through NETCONF or MIB.
- The password of a portal user is changed online on the login page.

For RADIUS SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view

   system-view

2. Enable SNMP notifications for password changes of local users.

   snmp-agent trap enable local-server [**manage-password-change** | **network-password-change**] *

By default, all SNMP notifications are disabled for password changes of local users.

Display and maintenance commands for local users and local user groups

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display pending registration requests for local guests.	**display local-guest waiting-approval** [**user-name** *user-name*]
Display the local user configuration and online user statistics.	**display local-user** [**class** { **manage** | **network** [**guest**] } | **idle-cut** { **disable** | **enable** } | **service-type** { **ftp** | **http** | **https** | **lan-access** | **portal** | **ssh** | **telnet** | **terminal** } | **state** { **active** | **block** } | **user-name** *user-name* **class** { **manage** | **network** [**guest**] } | **vlan** *vlan-id*]
Display user group configuration.	**display user-group** { **all** | **name** *group-name* }
Clear pending registration requests for local guests.	**reset local-guest waiting-approval** [**user-name** *user-name*]

Configuring RADIUS

RADIUS tasks at a glance

To configure RADIUS, perform the following tasks:

1. Configuring an EAP profile

   To perform EAP-based RADIUS server status detection, you must configure an EAP profile and specify the EAP profile in a test profile.
2. Configuring a test profile for RADIUS server status detection

   To detect the status of a RADIUS server, you must configure a test profile and configure the RADIUS server to use the test profile in a RADIUS scheme.
3. Creating a RADIUS scheme
4. Specifying RADIUS authentication servers
5. Specifying the RADIUS accounting servers
6. Specifying the shared keys for secure RADIUS communication

   Perform this task if no shared keys are specified when configuring RADIUS authentication or accounting servers.
7. Specifying the MPLS L3VPN instance for a RADIUS scheme

   Perform this task if no MPLS L3VPN instances are specified when configuring RADIUS authentication or accounting servers.
8. (Optional.) Setting the status of RADIUS servers
9. (Optional.) Setting RADIUS timers
10. (Optional.) Configuring parameters for RADIUS packets
    - Specifying the source IP address for outgoing RADIUS packets

- Setting the username format and traffic statistics units
- Setting the maximum number of RADIUS request transmission attempts
- Setting the maximum number of real-time accounting attempts
- Setting the DSCP priority for RADIUS packets

11. (Optional.) Configuring parameters for RADIUS attributes
    - Configuring the format of the RADIUS NAS-Port attribute
    - Configuring the Login-Service attribute check method for SSH, FTP, and terminal users
    - Interpreting the RADIUS class attribute as CAR parameters
    - Configuring the MAC address format for the RADIUS Called-Station-Id attribute
    - Configuring the MAC address format for the RADIUS Calling-Station-Id attribute
    - Configuring the format of RADIUS attribute 87
    - Setting the data measurement unit for the Remanent_Volume attribute
    - Including subattribute 218 of vendor 25506 in outgoing RADIUS packets
    - Configuring the RADIUS attribute translation feature
12. (Optional.) Configuring extended RADIUS features
    - Associating a microsegment with a VSI
    - Configuring RADIUS stop-accounting packet buffering
    - Enabling forcibly sending stop-accounting packets
    - Enabling the RADIUS server load sharing feature
    - Specifying a RADIUS server selection mode for reauthentication
    - Configuring the RADIUS accounting-on feature
    - Configuring the RADIUS session-control feature
    - Configuring the RADIUS DAS feature
    - Configuring the device to preferentially process RADIUS authentication requests
    - Enabling SNMP notifications for RADIUS
    - Disabling the RADIUS service

Restrictions and guidelines for RADIUS configuration

If the authentication server in a RADIUS scheme is provided by the RADIUS server feature on the device, you need to configure only the following items for the RADIUS scheme:

- RADIUS authentication server.
- Shared key for RADIUS communication.
- Username format for interaction with the RADIUS server.

Configuring an EAP profile

About this task

An EAP profile is a collection of EAP authentication settings, including the EAP authentication method and the CA certificate file to be used for some EAP authentication methods.

Restrictions and guidelines

You can specify an EAP profile in multiple test profiles.

You can configure a maximum of 16 EAP profiles.

Prerequisites

Before you specify a CA certificate file, use FTP or TFTP to transfer the CA certificate file to the root directory of the default storage medium on the device.

In an IRF fabric, make sure the CA certificate file exists in the root directory of the default storage medium on the master device before you specify the file.

Procedure

1. Enter system view.

   system-view

2. Create an EAP profile and enter EAP profile view.

   eap-profile *eap-profile-name*

3. Specify the EAP authentication method.

   method { **md5** | **peap-gtc** | **peap-mschapv2** | **ttls-gtc** | **ttls-mschapv2** }

   By default, the EAP authentication method is MD5-challenge.

4. Specify a CA certificate file for EAP authentication.

   ca-file *file-name*

   By default, no CA certificate file is specified for EAP authentication.

   You must specify a CA certificate file to verify the RADIUS server certificate if the EAP authentication method is PEAP-GTC, PEAP-MSCHAPv2, TTLS-GTC, or TTLS-MSCHAPv2.

Configuring a test profile for RADIUS server status detection

About this task

To detect the reachability or availability of a RADIUS authentication server, specify a test profile for the RADIUS server when you specify the server in a RADIUS scheme. With the test profile, the device refreshes the RADIUS server status at each detection interval according to the detection result. If the server is unreachable or unavailable, the device sets the status of the server to blocked. If the server is reachable or available, the device sets the status of the server to active.

The device supports the following RADIUS server status detection methods:

- **Simple detection**—For a RADIUS server, the device simulates an authentication request with the username and password specified in the test profile used by the server. The authentication request is sent to the RADIUS server within each detection interval. The device determines that the RADIUS server is reachable if the device receives a response from the server within the interval.
- **EAP-based detection**—For a RADIUS server, the device simulates an EAP authentication with the username and password specified in the test profile used by the server. The simulated EAP authentication starts at the beginning of each detection interval. If the EAP authentication completes within a detection interval, the device determines that the RADIUS server is available.

Simulating a complete EAP authentication process, EAP-based detection provides more reliable detection results than simple detection. As a best practice, configure EAP-based detection on a network environment where EAP authentication is configured.

Restrictions and guidelines

You can configure multiple test profiles in the system.

The device starts detecting the status of a RADIUS authentication server only if an existing test profile is specified for the server.

If you specify a nonexistent EAP profile in a test profile, the device performs simple detection for the RADIUS servers that use the test profile. After the EAP profile is configured, the device will start EAP-based detection at the next detection interval.

The device stops detecting the status of a RADIUS server when one of the following operations is performed:

- The RADIUS server is removed from the RADIUS scheme.
- The test profile configuration for the RADIUS server is removed in RADIUS scheme view.
- The test profile specified for the RADIUS server is deleted.
- The RADIUS server is manually set to the blocked state.
- The RADIUS scheme that contains the RADIUS server is deleted.

Procedure

1. Enter system view.

   system-view

2. Configure a test profile for detecting the status of RADIUS authentication servers.

   radius-server test-profile *profile-name* **username** *name* [**password** { **cipher** | **simple** } *string*] [**interval** *interval*] [**confirm** | **eap-profile** *eap-profile-name*]

Creating a RADIUS scheme

Restrictions and guidelines

You can configure a maximum of 16 RADIUS schemes. A RADIUS scheme can be used by multiple ISP domains.

Procedure

1. Enter system view.

   system-view

2. Create a RADIUS scheme and enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

Specifying RADIUS authentication servers

About this task

A RADIUS authentication server completes authentication and authorization together, because authorization information is piggybacked in authentication responses sent to RADIUS clients.

You can specify one primary authentication server and a maximum of 16 secondary authentication servers for a RADIUS scheme. Secondary servers provide AAA services when the primary server becomes unreachable. The device searches for an active server in the order the secondary servers are configured.

When RADIUS server load sharing is enabled, the device distributes the workload over all servers without considering the primary and secondary server roles. The device checks the weight value and number of currently served users for each active server, and then determines the most appropriate server in performance to receive an authentication request.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

A RADIUS authentication server can function as the primary authentication server for one scheme and a secondary authentication server for another scheme at the same time.

Two authentication servers in a scheme, primary or secondary, cannot have the same combination of VPN instance, host name, IP address, and port number.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Specify the primary RADIUS authentication server.

   primary authentication { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **ssl-client-policy** *policy-name* | **test-profile** *profile-name* | **vpn-instance** *vpn-instance-name* | **weight** *weight-value*] *

   By default, no primary RADIUS authentication server is specified.

   The **weight** keyword takes effect only when the RADIUS server load sharing feature is enabled for the RADIUS scheme.

4. (Optional.) Specify a secondary RADIUS authentication server.

   secondary authentication { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **ssl-client-policy** *policy-name* | **test-profile** *profile-name* | **vpn-instance** *vpn-instance-name* | **weight** *weight-value*] *

   By default, no secondary RADIUS authentication servers are specified.

   The **weight** keyword takes effect only when the RADIUS server load sharing feature is enabled for the RADIUS scheme.

Specifying the RADIUS accounting servers

About this task

You can specify one primary accounting server and a maximum of 16 secondary accounting servers for a RADIUS scheme. Secondary servers provide AAA services when the primary server becomes unavailable. The device searches for an active server in the order the secondary servers are configured.

When RADIUS server load sharing is enabled, the device distributes the workload over all servers without considering the primary and secondary server roles. The device checks the weight value and number of currently served users for each active server, and then determines the most appropriate server in performance to receive an accounting request.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

A RADIUS accounting server can function as the primary accounting server for one scheme and a secondary accounting server for another scheme at the same time.

Two accounting servers in a scheme, primary or secondary, cannot have the same combination of VPN instance, host name, IP address, and port number.

RADIUS does not support accounting for FTP, SFTP, and SCP users.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

radius scheme *radius-scheme-name*

3. Specify the primary RADIUS accounting server.
primary accounting { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **ssl-client-policy** *policy-name* | **vpn-instance** *vpn-instance-name* | **weight** *weight-value*] *

   By default, no primary RADIUS accounting server is specified.

   The **weight** keyword takes effect only when the RADIUS server load sharing feature is enabled for the RADIUS scheme.

4. (Optional.) Specify a secondary RADIUS accounting server.
secondary accounting { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **ssl-client-policy** *policy-name* | **vpn-instance** *vpn-instance-name* | **weight** *weight-value*] *

   By default, no secondary RADIUS accounting servers are specified.

   The **weight** keyword takes effect only when the RADIUS server load sharing feature is enabled for the RADIUS scheme.

Specifying the shared keys for secure RADIUS communication

About this task

The RADIUS client and server use the MD5 algorithm and shared keys to generate the Authenticator value for packet authentication and user password encryption. The client and server must use the same key for each type of communication.

A key configured in this task is for all servers of the same type (accounting or authentication) in the scheme. The key has a lower priority than a key configured individually for a RADIUS server.

Restrictions and guidelines

The shared key configured on the device must be the same as the shared key configured on the RADIUS server.

Procedure

1. Enter system view.
system-view
2. Enter RADIUS scheme view.
radius scheme *radius-scheme-name*
3. Specify a shared key for secure RADIUS communication.
key { **accounting** | **authentication** } { **cipher** | **simple** } *string*

   By default, no shared key is specified for secure RADIUS communication.

Specifying the MPLS L3VPN instance for a RADIUS scheme

About this task

The VPN instance specified for a RADIUS scheme applies to all authentication and accounting servers in that scheme. If a VPN instance is also configured for an individual RADIUS server, the VPN instance specified for the RADIUS scheme does not take effect on that server.

Procedure

1. Enter system view.
system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Specify a VPN instance for the RADIUS scheme.

   vpn-instance *vpn-instance-name*

   By default, a RADIUS scheme belongs to the public network.

Setting the status of RADIUS servers

About this task

To control the RADIUS servers with which the device communicates when the current servers are no longer available, set the status of RADIUS servers to blocked or active. You can specify one primary RADIUS server and multiple secondary RADIUS servers. The secondary servers function as the backup of the primary server. When the RADIUS server load sharing feature is disabled, the device chooses servers based on the following rules:

- When the primary server is in active state, the device first tries to communicate with the primary server. If the primary server is unreachable, the device searches for an active secondary server in the order the servers are configured.
- When one or more servers are in active state, the device tries to communicate with these active servers only, even if the servers are unavailable.
- When all servers are in blocked state, the device only tries to communicate with the primary server.
- If a server is unreachable, the device performs the following operations:
  - Changes the server status to blocked.
  - Starts a quiet timer for the server.
  - Tries to communicate with the next secondary server in active state that has the highest priority.
- When the quiet timer of a server expires or you manually set the server to the active state, the status of the server changes back to active. The device does not check the server again during the authentication or accounting process.
- The search process continues until the device finds an available secondary server or has checked all secondary servers in active state. If no server is reachable, the device considers the authentication or accounting attempt a failure.
- When you remove a server in use, communication with the server times out. The device looks for a server in active state by first checking the primary server, and then checking secondary servers in the order they are configured.
- When a RADIUS server's status changes automatically, the device changes this server's status accordingly in all RADIUS schemes in which this server is specified.
- When a RADIUS server is manually set to blocked, server detection is disabled for the server, regardless of whether a test profile has been specified for the server. When the RADIUS server is set to active state, server detection is enabled for the server on which an existing test profile is specified.

By default, the device sets the status of all RADIUS servers to active. However, in some situations, you must change the status of a server. For example, if a server fails, you can change the status of the server to blocked to avoid communication attempts to the server.

Restrictions and guidelines

The configured server status cannot be saved to any configuration file, and can only be viewed by using the **display radius scheme** command.

After the device restarts, all servers are restored to the active state.

The device selects a reachable server for the authentication or accounting of a new user according to the server selection rules in this section if the RADIUS server load sharing feature is disabled. However, these rules are inapplicable to the reauthentication of online users if the RADIUS server selection mode for reauthentication is set to inherit by using the **reauthentication server-select inherit** command.

Procedure

1. Enter system view.

   system-view
2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*
3. Set the RADIUS server status. Choose the following tasks as needed:
   - Set the status of the primary RADIUS authentication server.

     state primary authentication { **active** | **block** }
   - Set the status of the primary RADIUS accounting server.

     state primary accounting { **active** | **block** }
   - Set the status of a secondary RADIUS authentication server.

     state secondary authentication [{ *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **vpn-instance** *vpn-instance-name*] *] { **active** | **block** }
   - Set the status of a secondary RADIUS accounting server.

     state secondary accounting [{ *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **vpn-instance** *vpn-instance-name*] *] { **active** | **block** }

   By default, a RADIUS server is in active state.

Setting RADIUS timers

About this task

The device uses the following types of timers to control communication with a RADIUS server:

- **Server response timeout timer** (**response-timeout**)—Defines the RADIUS request retransmission interval. The timer starts immediately after a RADIUS request is sent. If the device does not receive a response from the RADIUS server before the timer expires, it resends the request.
- **Server quiet timer** (**quiet**)—Defines the duration to keep an unreachable server in blocked state. If one server is not reachable, the device changes the server status to blocked, starts this timer for the server, and tries to communicate with another server in active state. After the server quiet timer expires, the device changes the status of the server back to active.
- **Real-time accounting timer** (**realtime-accounting**)—Defines the intervals at which the device sends real-time accounting packets to the RADIUS accounting server for online users.

Restrictions and guidelines

Consider the number of secondary servers when you configure the maximum number of RADIUS packet transmission attempts and the RADIUS server response timeout timer. If the RADIUS scheme includes many secondary servers, the retransmission process might be too long and the client connection in the access module, such as Telnet, can time out.

When the client connections have a short timeout period, a large number of secondary servers can cause the initial authentication or accounting attempt to fail. In this case, reconnect the client rather than adjusting the RADIUS packet transmission attempts and server response timeout timer.

Typically, the next attempt will succeed, because the device has blocked the unreachable servers to shorten the time to find a reachable server.

Make sure the server quiet timer is set correctly. A timer that is too short might result in frequent authentication or accounting failures. This is because the device will continue to attempt to communicate with an unreachable server that is in active state. A timer that is too long might temporarily block a reachable server that has recovered from a failure. This is because the server will remain in blocked state until the timer expires.

A short real-time accounting interval helps improve accounting precision but requires many system resources. When there are 1000 or more users, set the interval to 15 minutes or longer.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Set RADIUS timers. Choose the following tasks as needed:
   - Set the RADIUS server response timeout timer.
     timer response-timeout *seconds*
     The default setting is 3 seconds.
   - Set the quiet timer for the servers.
     timer quiet *minutes*
     The default setting is 5 minutes.
   - Set the real-time accounting timer.
     timer realtime-accounting *interval* [**second**]
     The default setting is 12 minutes.

Specifying the source IP address for outgoing RADIUS packets

About this task

The source IP address of RADIUS packets that a NAS sends must match the IP address of the NAS configured on the RADIUS server. A RADIUS server identifies a NAS by its IP address. Upon receiving a RADIUS packet, the RADIUS server checks the source IP address of the packet.

- If it is the IP address of a managed NAS, the server processes the packet.
- If it is not the IP address of a managed NAS, the server drops the packet.

Before sending a RADIUS packet, the NAS selects a source IP address in the following order:

1. The source IP address specified for the RADIUS scheme.
2. The source IP address specified in system view for the VPN or public network, depending on where the RADIUS server resides.
3. The IP address of the outbound interface specified by the route.

In an M-LAG system, you must specify the source IP address for outgoing RADIUS packets on both the M-LAG member devices. Each M-LAG member device selects a source IP address in order as described previously. To make user traffic switchover caused by primary/secondary M-LAG member device switchover transparent to the RADIUS server, the source IP address of outgoing RADIUS packets must remain unchanged after switchover. You must specify the source IP address depending on the load sharing mode for user authentication on M-LAG interfaces:

- In centralized mode, you must specify the same source IP address on both the M-LAG member devices.

  When an M-LAG member device fails, the active M-LAG member device uses the source IP address for outgoing RADIUS packets sent for users authenticated on the failed M-LAG member device.
- In distributed mode, use either of the following methods to specify source IP addresses for outgoing RADIUS packets:
  - Specify different source addresses on the M-LAG member devices. The M-LAG member devices will automatically advertise their source addresses to each other.
  - Specify a local and peer source IP address pair on both of the M-LAG member devices. Make sure the peer source IP address on one M-LAG member device is the local IP address on the other M-LAG member device.

  When one M-LAG member device fails, the other member device uses the automatically obtained or manually configured peer source IP address to send RADIUS packets for users authenticated on the failed member device.

Restrictions and guidelines for source IP address configuration

You can specify a source IP address for outgoing RADIUS packets in RADIUS scheme view or in system view.

- The IP address specified in RADIUS scheme view applies only to one RADIUS scheme.
- The IP address specified in system view applies to all RADIUS schemes.

The source IP address of RADIUS packets that a NAS sends must match the IP address of the NAS that is configured on the RADIUS server.

As a best practice, specify a loopback interface address as the source IP address for outgoing RADIUS packets to avoid RADIUS packet loss caused by physical port errors.

The source address of outgoing RADIUS packets is typically the IP address of an egress interface on the NAS to communicate with the RADIUS server. However, in some situations, you must change the source IP address. For example, when VRRP is configured for stateful failover, configure the virtual IP of the uplink VRRP group as the source address.

You can directly specify a source IP address for outgoing RADIUS packets or specify a source interface to provide the source IP address for outgoing RADIUS packets. The source interface configuration and the source IP address configuration overwrite each other.

In an M-LAG system, you must use the **nas-ip** command to specify a virtual IP address for the M-LAG system as the source IP address of RADIUS packets. For more information about virtual IP addresses for the M-LAG system, see M-LAG configuration in *Layer 2—LAN Switching Configuration Guide*.

Specifying a source interface or source IP address for all RADIUS schemes

1. Enter system view.

   system-view
2. Specify a source interface or source IP address for outgoing RADIUS packets.

   radius nas-ip { **interface** *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] }

   By default, the source IP address of an outgoing RADIUS packet is the primary IPv4 address or the IPv6 address of the outbound interface.

Specifying a source interface or source IP address for a RADIUS scheme

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Specify a source interface or source IP address for outgoing RADIUS packets.

   nas-ip [**m-lag** { **local** | **peer** }] { *ipv4-address* | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, the source IP address of an outgoing RADIUS packet is that specified by using the **radius nas-ip** command in system view. If the **radius nas-ip** command is not used, the source IP address is the primary IP address of the outbound interface.

   The **m-lag** { **local** | **peer** } parameters are applicable only to an M-LAG system. Specify a source IP address for outgoing RADIUS packets on each M-LAG member device as follows, depending on the load sharing mode for user authentication on M-LAG interfaces:

   - In centralized mode, execute the **nas-ip** command with or without the **m-lag local parameters to specify the local source IP address. The two methods have the same result except that you must use the same method on both devices.**
   - In distributed mode, execute the **nas-ip** command with the **m-lag local parameters and with the m-lag peer parameters to specify the local and peer source IP addresses, respectively. Alternatively,** execute the **nas-ip** command with or without the **m-lag local parameters to specify the local source IP address. These methods have the same result, except that you must use the same method on both devices**.

   If you do not specify the keywords, the system does not send accounting-on packets when the device restarts.

Setting the username format and traffic statistics units

About this task

A username is in the *userid@isp-name* format, where the *isp-name* part represents the user's ISP domain name. By default, the ISP domain name is included in a username. However, older RADIUS servers might not recognize usernames that contain the ISP domain names. In this case, you can configure the device to remove the domain name of each username to be sent.

The device reports online user traffic statistics in accounting packets. The traffic measurement units are configurable.

Restrictions and guidelines

If two or more ISP domains use the same RADIUS scheme, configure the RADIUS scheme to keep the ISP domain name in usernames for domain identification.

For accounting accuracy, make sure the traffic statistics units configured on the device and on the RADIUS accounting servers are the same.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Set the format for usernames sent to the RADIUS servers.

   user-name-format { **keep-original** | **with-domain** | **without-domain** }

   By default, the ISP domain name is included in a username.

   If the device is specified as the RADIUS server in the scheme, the username format must be set to **without-domain**.

4. Set the data flow and packet measurement units for traffic statistics.

   data-flow-format { **data** { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** } | **packet** { **giga-packet** | **kilo-packet** | **mega-packet** | **one-packet** } }*

   By default, traffic is counted in bytes and packets.

Setting the maximum number of RADIUS request transmission attempts

About this task

RADIUS uses UDP packets to transfer data. Because UDP communication is not reliable, RADIUS uses a retransmission mechanism to improve reliability. A RADIUS request is retransmitted if the NAS does not receive a server response for the request within the response timeout timer. For more information about the RADIUS server response timeout timer, see "Setting the status of RADIUS servers."

You can set the maximum number for the NAS to retransmit a RADIUS request to the same server. When the maximum number is reached, the NAS tries to communicate with other RADIUS servers in active state. If no other servers are in active state at the time, the NAS considers the authentication or accounting attempt a failure.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Set the maximum number of RADIUS request transmission attempts.

   retry *retries*

   By default, the maximum number is 3 for RADIUS request transmission attempts.

Setting the maximum number of real-time accounting attempts

About this task

If you set the maximum number of real-time accounting attempts, the device will disconnect users from whom no accounting responses are received within the permitted attempts.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Set the maximum number of real-time accounting attempts.

   retry realtime-accounting *retries*

   By default, the maximum number is 5 for real-time accounting attempts.

Setting the DSCP priority for RADIUS packets

About this task

DSCP priority determines the transmission priority of RADIUS packets. A larger value represents a higher priority. DSCP priority is contained in the ToS field of the IPv4 header and in the Traffic Class field of the IPv6 header.

Procedure

1. Enter system view.
   system-view
2. Set the DSCP priority for RADIUS packets.
   radius [**ipv6**] **dscp** *dscp-value*
   By default, the DSCP priority is 0 for RADIUS packets.

Configuring the format of the RADIUS NAS-Port attribute

About this task

The device supports the following formats for the RADIUS NAS-Port attribute (attribute 5):

- **Default format**—Contains the following portions:
  - 8-bit IRF member ID.
  - 4-bit slot number.
  - 8-bit interface index.
  - 12-bit VLAN ID.
- **Port format**—Contains the last segment for the interface number of the interface through which a user accesses the device. For example, if a user accesses the device through GigabitEthernet 1/0/2, 2 is used as the value for the RADIUS NAS-Port attribute.

Restrictions and guidelines

RADIUS servers of different types might have different requirements for the format of the NAS-Port attribute. To ensure correct RADIUS packet exchange, make sure the format of the NAS-Port attribute meets the requirements of the RADIUS servers.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Configure the format of the RADIUS NAS-Port attribute as the port format.
   attribute 5 format port
   By default, the RADIUS NAS-Port attribute uses the default format.

Configuring the Login-Service attribute check method for SSH, FTP, and terminal users

About this task

The Login-Service attribute (RADIUS attribute 15) identifies the service that can be used to connect a user to the device. For example, a value of 0 represents the Telnet service. This attribute is

contained in the Access-Accept message sent from the RADIUS server to the device. To log in to the device, the access service type of a RADIUS authentication user must match the Login-Service attribute value in the Access-Accept message.

The RADIUS standards do not assign a Login-Service attribute value for the SSH, FTP, HTTP, HTTPS, or terminal users. To perform service type consistency checks for these types of login users, H3C defines the extended Login-Service attribute values in Table 3.

Table 3 Extended Login-Service attribute values

Attribute value	Service type
50	SSH
51	**FTP**
52	**Terminal**
53	**HTTP**
54	**HTTPS**

The device provides the following Login-Service attribute check methods:

- **Strict**—Checks the service types of login users based on the standard and extended attribute values. SSH, FTP, HTTP, HTTPS, and terminal users can pass the check only if the Access-Accept messages for them contain the extended Login-Service attribute values specified for them.
- **Loose**—Checks the service types of login users based only on the standard attribute values. SSH, FTP, HTTP, HTTPS, and terminal users pass the check if the attribute value is 0.

Restrictions and guidelines

Use the loose check method if the server does not issue the extended Login-Service attribute values for SSH, FTP, HTTP, HTTPS, and terminal users.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Configure the Login-Service attribute check method for SSH, FTP, and terminal users.
   attribute 15 check-mode { **loose** | **strict** }
   The default check method is strict.

Interpreting the RADIUS class attribute as CAR parameters

About this task

A RADIUS server may deliver CAR parameters for user-based traffic monitoring and control by using the RADIUS class attribute (attribute 25) in RADIUS packets. You can configure the device to interpret the class attribute to CAR parameters.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*

3. Interpret the RADIUS class attribute as CAR parameters.

   attribute 25 car

   By default, the RADIUS class attribute is not interpreted as CAR parameters.

Configuring the MAC address format for the RADIUS Called-Station-Id attribute

Restrictions and guidelines

RADIUS servers of different types might have different requirements for the MAC address format in the RADIUS Called-Station-Id attribute (attribute 30). Configure the MAC address format for this attribute to meet the requirements of the RADIUS servers.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Configure the MAC address format for the RADIUS Called-Station-Id attribute.

   attribute 30 mac-format section { **one** | { **six** | **three** } **separator** *separator-character* } { **lowercase** | **uppercase** }

   By default, the MAC address in the RADIUS Called-Station-Id attribute is in the format of HH-HH-HH-HH-HH-HH. The MAC address is separated by hyphen (-) into six sections with letters in upper case.

Configuring the MAC address format for the RADIUS Calling-Station-Id attribute

Restrictions and guidelines

RADIUS servers of different types might have different requirements for the MAC address format in the RADIUS Calling-Station-Id attribute (attribute 31). Configure the MAC address format for this attribute to meet the requirements of the RADIUS servers.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Configure the MAC address format for the RADIUS Calling-Station-Id attribute.

   attribute 31 mac-format section { **one** | { **six** | **three** } **separator** *separator-character* } { **lowercase** | **uppercase** }

   By default, the MAC address in the RADIUS Calling-Station-Id attribute is in the format of HH-HH-HH-HH-HH-HH. The MAC address is separated by hyphen (-) into six sections with letters in upper case.

Configuring the format of RADIUS attribute 87

About this task

RADIUS attribute 87 is the NAS-Port-Id attribute. This attribute has the following format types:

- **Default format**—The default format varies by user access type.
  - For portal users, the NAS-Port-Id attribute in this format contains the following portions:
    - 2-bit slot number.
    - 2-bit 0s.
    - 3-bit interface index.
    - 9-bit VLAN ID.
  - For 802.1X and MAC authentication users, the NAS-Port-Id attribute is in the format of **slot=***xx***;subslot=***xx***;port=***xx***;vlanid=***xx*.
    - **slot**—IRF member ID.
    - **subslot**—Slot number.
    - **port**—Interface index.
    - **vlanid**—VLAN ID.
  - For login users, the NAS-Port-Id attribute is not included in RADIUS packets.
- **Interface name format**—Contains the name of the interface through which a user accesses the device. For example, if a user accesses the device through GigabitEthernet 1/0/1, GigabitEthernet 1/0/1 is used as the value for the RADIUS NAS-Port-Id attribute.

Restrictions and guidelines

RADIUS servers of different types might have different requirements for the format of the NAS-Port-Id attribute. To ensure correct RADIUS packet exchange, configure the format of the NAS-Port-Id attribute to meet the requirements of the RADIUS servers.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Configure the format of RADIUS attribute 87 as the interface name format.
   attribute 87 format interface-name
   By default, the default format is used for RADIUS attribute 87.

Setting the data measurement unit for the Remanent_Volume attribute

About this task

The RADIUS server uses the Remanent_Volume attribute in authentication or real-time accounting responses to notify the device of the current amount of data available for online users.

Restrictions and guidelines

Make sure the configured measurement unit is the same as the user data measurement unit on the RADIUS server.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Set the data measurement unit for the Remanent_Volume attribute.

   attribute remanent-volume unit { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** }

   By default, the data measurement unit is kilobyte.

Including subattribute 218 of vendor 25506 in outgoing RADIUS packets

About this task

The RADIUS Vendor-Specific attribute (attribute 26) allows vendors to define extended attributes to implement functions that the standard RADIUS protocol does not provide. Vendor 25506 defines subattribute 218 to carry user DHCP option information.

To send user DHCP option information to RADIUS servers, perform this task to include subattribute 218 of vendor 25506 in outgoing RADIUS start-accounting and update-accounting requests.

In the current software version, only DHCP Option 55 and DHCP Option 61 can be carried in the subattribute.

Restrictions and guidelines

You can repeat the **include-attribute 218 vendor-id 25506** command to configure the device to encapsulate both DHCP Option 55 and DHCP Option 61 in the subattribute. The length of each option is limited to 246 bytes.

If you repeat this command multiple times with the same DHCP option specified, the most recent configuration takes effect.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Include subattribute 218 of vendor 25506 in outgoing RADIUS packets.

   include-attribute 218 vendor-id 25506 dhcp-option { **55** | **61** } * { **format1** | **format2** }

   By default, the device uses format 1 to encapsulate DHCP Option 61 in subattribute 218 of vendor 25506 in RADIUS packets.

Configuring the RADIUS attribute translation feature

About this task

The RADIUS attribute translation feature enables the device to work correctly with the RADIUS servers of different vendors that support RADIUS attributes incompatible with the device.

RADIUS attribute translation has the following implementations:

- **Attribute conversion**—Converts source RADIUS attributes into destination RADIUS attributes based on RADIUS attribute conversion rules.
- **Attribute rejection**—Rejects RADIUS attributes based on RADIUS attribute rejection rules.

When the RADIUS attribute translation feature is enabled, the device processes RADIUS packets as follows:

- For the sent RADIUS packets:
  - Deletes the rejected attributes from the packets.
  - Uses the destination RADIUS attributes to replace the attributes that match RADIUS attribute conversion rules in the packets.
- For the received RADIUS packets:
  - Ignores the rejected attributes in the packets.
  - Interprets the attributes that match RADIUS attribute conversion rules as the destination RADIUS attributes.

To identify proprietary RADIUS attributes, you can define the attributes as extended RADIUS attributes, and then convert the extended RADIUS attributes to device-supported attributes.

Restrictions and guidelines for RADIUS attribute translation configuration

Configure either conversion rules or rejection rules for a RADIUS attribute.

Configure either direction-based rules or packet type-based rules for a RADIUS attribute.

For direction-based translation of a RADIUS attribute, you can configure a rule for each direction (inbound or outbound). For packet type-based translation of a RADIUS attribute, you can configure a rule for each RADIUS packet type (RADIUS Access-Accept, RADIUS Access-Request, or RADIUS accounting).

Configuring the RADIUS attribute translation feature for a RADIUS scheme

1. Enter system view.

   system-view

2. (Optional.) Define an extended RADIUS attribute.

   radius attribute extended *attribute-name* [**vendor** *vendor-id*] **code** *attribute-code* **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** }

3. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

4. Enable the RADIUS attribute translation feature.

   attribute translate

   By default, this feature is disabled.

5. Configure a RADIUS attribute conversion rule or a RADIUS attribute reject rule. Choose the following tasks as needed:
   - Configure a RADIUS attribute conversion rule.

     attribute convert *src-attr-name* **to** *dest-attr-name* { { **access-accept** | **access-request** | **accounting** } * | { **received** | **sent** } * }

     By default, no RADIUS attribute conversion rules are configured.
   - Configure a RADIUS attribute rejection rule.

     attribute reject *attr-name* { { **access-accept** | **access-request** | **accounting** } * | { **received** | **sent** } * }

     By default, no RADIUS attribute rejection rules are configured.

Configuring the RADIUS attribute translation feature for a RADIUS DAS

1. Enter system view.
   system-view
2. (Optional.) Define an extended RADIUS attribute.
   radius attribute extended *attribute-name* [**vendor** *vendor-id*] **code** *attribute-code* **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** }
3. Enter RADIUS DAS view.
   radius dynamic-author server
4. Enable the RADIUS attribute translation feature.
   attribute translate
   By default, this feature is disabled.
5. Configure a RADIUS attribute conversion rule or a RADIUS attribute rejection rule. Choose the following tasks as needed:
   - Configure a RADIUS attribute conversion rule.
     attribute convert *src-attr-name* **to** *dest-attr-name* { { **coa-ack** | **coa-request** } * | { **received** | **sent** } * }
     By default, no RADIUS attribute conversion rules are configured.
   - Configure a RADIUS attribute rejection rule.
     attribute reject *attr-name* { { **coa-ack** | **coa-request** } * | { **received** | **sent** } * }
     By default, no RADIUS attribute rejection rules are configured.

Associating a microsegment with a VSI

About this task

Use this feature when microsegment-based access control is deployed on a VXLAN network.

When the RADIUS server assigns the microsegment and VSI attributes to a user, the device directly assigns the microsegment and VSI to the user so the user can access the related VXLAN resources.

When the RADIUS server assigns only the microsegment attribute but no VSI attribute to a user, the device will search for a VSI associated with the microsegment.

- If the device finds an associated VSI, it assigns the microsegment and the VSI to the user.
- If the device does not find an associated VSI, it assigns only the microsegment to the user.

Restrictions and guidelines

In a RADIUS scheme, a microsegment can be associated with only one VSI. Multiple microsegments can be associated with the same VSI. If you repeat the **microsegment associate** command to associate a microsegment with different VSIs, the most recent configuration takes effect.

Make sure the device can interpret microsegment IDs assigned by the RADIUS server. If the device cannot directly interpret microsegment IDs, use the attribute translation feature so the device can translate the server-assigned microsegment ID attribute to the H3C-Microsegment-Id attribute.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*

3. Associate a microsegment with a VSI.

   microsegment *microsegment-id* **associate vsi** *vsi-name*

   By default, no VSI is associated with a microsegment.

Configuring RADIUS stop-accounting packet buffering

About this task

The device sends RADIUS stop-accounting requests when it receives connection teardown requests from hosts or connection teardown commands from an administrator. However, the device might fail to receive a response for a stop-accounting request in a single transmission. Enable the device to buffer RADIUS stop-accounting requests that have not received responses from the accounting server. The device will resend the requests until responses are received.

To limit the transmission times, set a maximum number of transmission attempts that can be made for individual RADIUS stop-accounting requests. When the maximum attempts are made for a request, the device discards the buffered request.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Enable buffering of RADIUS stop-accounting requests to which no responses have been received.

   stop-accounting-buffer enable

   By default, the buffering feature is enabled.

4. (Optional.) Set the maximum number of transmission attempts for individual RADIUS stop-accounting requests.

   retry stop-accounting *retries*

   The default setting is 500.

Enabling forcibly sending stop-accounting packets

About this task

Typically, if the device does not send a start-accounting packet to the RADIUS server for an authenticated user, it does not send a stop-accounting packet when the user goes offline. If the server has generated a user entry for the user without start-accounting packets, it does not release the user entry when the user goes offline. This feature forces the device to send stop-accounting packets to the RADIUS server when the user goes offline for timely releasing the user entry on the server.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Enable the device to send stop-accounting packets when users for which no start-accounting packets are sent go offline.

   stop-accounting-packet send-force

By default, forcibly sending stop-accounting packets is disabled. The device does not send stop-accounting packets when users for which no start-accounting packets are sent go offline.

Enabling the RADIUS server load sharing feature

About this task

By default, the device communicates with RADIUS servers based on the server roles. It first attempts to communicate with the primary server, and, if the primary server is unreachable, it then searches for the secondary servers in the order they are configured. The first secondary server in active state is used for communication. In this process, the workload is always placed on the active server.

Use the RADIUS server load sharing feature to dynamically distribute the workload over multiple servers regardless of their server roles. The device forwards an AAA request to the most appropriate server of all active servers in the scheme after it compares the weight values and numbers of currently served users. Specify a weight value for each RADIUS server based on the AAA capacity of the server. A larger weight value indicates a higher AAA capacity.

In RADIUS server load sharing, once the device sends a start-accounting request to a server for a user, it forwards all subsequent accounting requests of the user to the same server. If the accounting server is unreachable, the device returns an accounting failure message rather than searching for another active accounting server.

Procedure

1. Enter system view.

   `system-view`
2. Enter RADIUS scheme view.

   `radius scheme` *`radius-scheme-name`*
3. Enable the RADIUS server load sharing feature.

   `server-load-sharing enable`

   By default, this feature is disabled.

Specifying a RADIUS server selection mode for reauthentication

About this task

Use this feature to configure the RADIUS server selection mechanism in reauthentication. The following RADIUS server selection modes are available:

- **Inherit**—The device uses the RADIUS server that performed authentication for a user to reauthenticate that user. This mode reduces the amount of time used in reauthentication. However, if the RADIUS server is unreachable, the reauthentication will fail.
- **Reselect**—The device searches for a reachable RADIUS server to reauthenticate a user. This mode requires more time than the inherit mode. However, this mode ensures that the device uses the optimal reachable RADIUS server for reauthentication. The following factors affect the RADIUS server selection:
  - Server configuration in the RADIUS scheme, including the configuration order.
  - Enabling status of the RADIUS server load sharing feature.
  - Status of the RADIUS servers in the RADIUS scheme.

Procedure

1. Enter system view.

   `system-view`

2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Specify a RADIUS server selection mode for reauthentication.
   reauthentication server-select { **inherit** | **reselect** }
   By default, the inherit mode is used.

Configuring the RADIUS accounting-on feature

About this task

When the accounting-on feature is enabled, the device automatically sends an accounting-on packet to the RADIUS server after the entire device reboots. Upon receiving the accounting-on packet, the RADIUS server logs out all online users so they can log in again through the device. Without this feature, users cannot log in again after the reboot, because the RADIUS server considers them to come online.

You can configure the interval for which the device waits to resend the accounting-on packet and the maximum number of retries.

The extended accounting-on feature enhances the accounting-on feature in a distributed architecture.

The extended accounting-on feature is applicable to LAN users. The user data is saved to the IRF member devices through which the users access the system. When the extended accounting-on feature is enabled, the system automatically sends an accounting-on packet to the RADIUS server after a member device reboots. The packet contains the member device identifier. Upon receiving the accounting-on packet, the RADIUS server logs out all online users that access the system through the member device. If no users have come online through the member device, the IRF fabric does not send an accounting-on packet after the member device reboots.

Restrictions and guidelines

For the extended accounting-on feature to take effect, the RADIUS server must run on IMC and the accounting-on feature must be enabled.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Enable accounting-on.
   accounting-on enable [**interval** *interval* | **send** *send-times*] *
   By default, the accounting-on feature is disabled.
4. (Optional.) Enable extended accounting-on.
   accounting-on extended
   By default, extended accounting-on is disabled.

Configuring the RADIUS session-control feature

About this task

Enable this feature for the RADIUS server to dynamically change the user authorization information (for example, authorization ACL, VLAN, user group, VSI, or blackhole MAC) or forcibly disconnect users by using session-control packets. This task enables the device to receive RADIUS session-control packets on UDP port 1812.

To verify the session-control packets sent from a RADIUS server, specify the RADIUS server as a session-control client to the device.

Restrictions and guidelines

The RADIUS session-control feature can only work with RADIUS servers running on IMC. The session-control client configuration takes effect only when the session-control feature is enabled.

Procedure

1. Enter system view.

   system-view

2. Enable the session-control feature.

   radius session-control enable

   By default, the session-control feature is disabled.

3. Specify a session-control client.

   radius session-control client { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**key** { **cipher** | **simple** } *string* | **vpn-instance** *vpn-instance-name*] *

   By default, no session-control clients are specified.

Configuring the RADIUS DAS feature

About this task

Dynamic Authorization Extensions (DAE) to RADIUS, defined in RFC 5176, can log off online users and change online user authorization information.

In a RADIUS network, the RADIUS server typically acts as the DAE client (DAC) and the NAS acts as the DAE server (DAS).

When the RADIUS DAS feature is enabled, the NAS performs the following operations:

1. Listens to the default or specified UDP port to receive DAE requests.
2. Logs off online users that match the criteria in the requests, changes their authorization information, shuts down or reboots their access ports, or reauthenticates the users.
3. Sends DAE responses to the DAC.

DAE defines the following types of packets:

- **Disconnect Messages (DMs)**—The DAC sends DM requests to the DAS to log off specific online users.
- **Change of Authorization Messages (CoA Messages)**—The DAC sends CoA requests to the DAS to change the authorization information of specific online users.

Procedure

1. Enter system view.

   system-view

2. Enable the RADIUS DAS feature and enter RADIUS DAS view.

   radius dynamic-author server

   By default, the RADIUS DAS feature is disabled.

3. Specify a RADIUS DAC.

   client { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**key** { **cipher** | **simple** } *string* | **ssl-client-policy** *policy-name* | **vpn-instance** *vpn-instance-name*] *

   By default, no RADIUS DACs are specified.

4. (Optional.) Specify the RADIUS DAS port.

port *port-number*

By default, the RADIUS DAS port is 3799.

5. (Optional.) Set the idle timeout for TLS connections of the RADIUS DAE service.
   timer tls-idle-timeout *timeout-value*

   By default, the idle timeout is 60 seconds for TLS connections.
6. (Optional.) Specify the TLS connection listening port for the RADIUS DAE service.
   tls-port *port-number*

   By default, the TLS connection listening port for the RADIUS DAE service is 2083.

Configuring the device to preferentially process RADIUS authentication requests

About this task

RADIUS requests include RADIUS authentication requests, RADIUS accounting-start requests, RADIUS accounting-update requests, and RADIUS accounting-stop requests. By default, the device processes the RADIUS requests in the sequence that the requests are initiated.

When a large number of users go offline and then try to come online immediately, authentication might fail for these users because of authentication request timeout. To resolve this issue, configure the device to preferentially process authentication requests.

Restrictions and guidelines

Do not perform this task if the RADIUS server identifies users by the username and does not allow repeated authentication for the same username. A violation might cause authentication failure for users that try to come online immediately after going offline.

As a best practice, do not perform this task when the device has online users.

Procedure

1. Enter system view.
   system-view
2. Configure the device to preferentially process RADIUS authentication requests.
   radius authentication-request first

   By default, the device processes RADIUS requests in the sequence that the requests are initiated.

Enabling SNMP notifications for RADIUS

About this task

When SNMP notifications are enabled for RADIUS, the SNMP agent supports the following notifications generated by RADIUS:

- **RADIUS server unreachable notification**—The RADIUS server cannot be reached. RADIUS generates this notification if it does not receive a response to an accounting or authentication request within the specified number of RADIUS request transmission attempts.
- **RADIUS server reachable notification**—The RADIUS server can be reached. RADIUS generates this notification for a previously blocked RADIUS server after the quiet timer expires.
- **Excessive authentication failures notification**—The number of authentication failures compared to the total number of authentication attempts exceeds the specified threshold.

For RADIUS SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

Make sure the RADIUS server status change notifications sent by the device can be recognized by the NMS. Choose a MIB node version depending on the NMS requirements. For more information about the MIB node versions, see AAA in *Security Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for RADIUS.

   snmp-agent trap enable radius [**accounting-server-down** | **accounting-server-up** | **authentication-error-threshold** | **authentication-server-down** | **authentication-server-up**] *

   By default, all SNMP notifications are disabled for RADIUS.

3. Set the version of RADIUS server status change MIB nodes.

   radius trap-version { **v1** | **v2** } [**accounting-server-down** | **accounting-server-up** | **authentication-server-down** | **authentication-server-up**] *

   By default, the device sends notifications about RADIUS server status change MIB nodes over SNMPv1.

Enabling RADIUS server parallel authentication

About this task

The implementation mechanism of this feature varies by authentication method as follows:

- For 802.1X EAP termination authentication or MAC authentication, the device simultaneously sends authentication requests to all servers in Active state, without distinguishing between primary and secondary servers. If any one of the servers responds with successful authentication, the user authentication is considered successful. In the case where user authentication fails on all servers, authentication fail-permit is triggered for the user. User authentication is considered failed if no server responds or if all servers respond with a failure result at least once.
- For 802.1X EAP relay authentication, the device uses the primary and secondary server mode for authentication. If the primary server responds with a failure result, the device checks whether any other servers are in Active state. If an active server is detected, the system notifies the device to send an authentication request to the server for re-authentication. If no active server exists, the device considers that the user authentication fails. In the authentication process, an authentication request is sent to the next active server only when the previous authentication server responds with a fail or does not respond. If any one of the servers responds with successful authentication, the user authentication is considered successful. In the case where user authentication fails on all servers, authentication fail-permit is triggered for the user. User authentication is considered failed if no server responds or if all servers respond with a failure result at least once.

Restrictions and guidelines

If you enable both this feature and RADIUS server load sharing (**server-load-sharing enable**), RADIUS server load sharing does not take effect.

If you enable this feature and specify a RADIUS server selection mode for authentication (**reauthentication server-select**), the specified selection mode does not take effect.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Enable RADIUS server parallel authentication.
   server-parallel-auth enable
   By default, RADIUS server parallel authentication is disabled.

Configuring the idle timeout for TLS connections in RADIUS authentication

About this task

After the device processes the last authentication or accounting request, it uses the idle timeout configured for TLS connections in the RADIUS scheme of the last request to update the idle timeout timer. If the timer expires but no authentication or accounting request is received, the system disconnects the TLS connection. Setting the idle timeout to 0 disables the system from disconnecting TLS connections due to timeout.

If you change the idle timeout under a RADIUS scheme from 0 to a non-zero value, the system traverses the connections of the servers under the scheme and updates the idle timeout to the new value.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Specify the idle timeout for TLS connections in RADIUS authentication.
   timer tls-idle-timeout *timeout-value*
   By default, the idle timeout is 60 seconds for TLS connections in RADIUS authentication.

Disabling the RADIUS service

About this task

By default, the RADIUS service is enabled. The device can send and receive RADIUS packets. Attackers might use RADIUS session-control and DAE ports to attack the device. To protect the device when such an attack occurs, disable the RADIUS service temporarily on the device. After the network is secure, re-enable the RADIUS service.

If settings on the RADIUS servers require modification or the RADIUS servers cannot provide services temporarily, you can temporarily disable the RADIUS service on the device.

When the RADIUS service is disabled, the device stops sending and receiving RADIUS packets. If a new user comes online, the device uses the backup authentication, authorization, or accounting method to process that user. If the device has not finished requesting authentication or accounting for a user before the RADIUS service is disabled, it uses the following rules to process that user:

- If the device has sent RADIUS authentication requests for that user to a RADIUS server, the device processes that user depending on whether it receives a response from the RADIUS server.

    - If the device receives a response from the RADIUS server, it uses the response to determine whether that user has passed authentication. If that user has passed authentication, the device assigns authorization information to that user according to the response.
    - If the device does not receive any response from the RADIUS server, it attempts to use the backup authentication method to authenticate that user.
- If the device has sent RADIUS start-accounting requests for that user to a RADIUS server, the device processes that user depending on whether it receives a response from the RADIUS server.
    - If the device receives a response from the RADIUS server, it allows that user to come online. However, the device cannot send out accounting-update or stop-accounting requests to the RADIUS server. It cannot buffer the accounting requests, either. When that user goes offline, the RADIUS server cannot log off that user in time. The accounting result might be inaccurate.
    - If the device does not receive any response from the RADIUS server, it attempts to use the backup accounting method.

Restrictions and guidelines

Disabling the RADIUS service does not affect the RADIUS server feature of the device.

The authentication, authorization, and accounting processes undertaken by other methods are not switched to RADIUS when you re-enable the RADIUS service.

Procedure

1. Enter system view.

   `system-view`
2. Disable the RADIUS service.

   `undo radius enable`

   By default, the RADIUS service is enabled.

   To re-enable the RADIUS service, use the **`radius enable`** command.

Display and maintenance commands for RADIUS

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display information about globally cached RADIUS packets.	**`display radius buffer`**
Display the RADIUS scheme configuration.	**`display radius scheme`** [*`radius-scheme-name`*]
Display authentication and accounting load statistics for all RADIUS servers.	**`display radius server-load statistics`**
Display RADIUS packet statistics.	**`display radius statistics`**
Display information about buffered RADIUS stop-accounting requests to which no responses have been received.	**`display stop-accounting-buffer`** { **`radius-scheme`** *`radius-scheme-name`* | **`session-id`** *`session-id`* | **`time-range`** *`start-time end-time`* | **`user-name`** *`user-name`* }
Clear history authentication and accounting load statistics for all RADIUS servers.	**`reset radius server-load statistics`**

Task	Command
Clear RADIUS statistics.	**reset radius statistics**
Clear the buffered RADIUS stop-accounting requests to which no responses have been received.	**reset stop-accounting-buffer** { **radius-scheme** *radius-scheme-name* | **session-id** *session-id* | **time-range** *start-time end-time* | **user-name** *user-name* }

Configuring HWTACACS

HWTACACS tasks at a glance

To configure HWTACACS, perform the following tasks:

1. Creating an HWTACACS scheme
2. Specifying the HWTACACS authentication servers
3. Specifying the HWTACACS authorization servers
4. Specifying the HWTACACS accounting servers
5. Specifying the shared keys for secure HWTACACS communication

   Perform this task if no shared keys are specified when configuring HWTACACS servers.
6. Specifying an MPLS L3VPN instance for the scheme

   Perform this task if no MPLS L3VPN instances are specified when configuring HWTACACS servers.
7. (Optional.) Setting HWTACACS timers
8. (Optional.) Configuring parameters for HWTACACS packets
   - Specifying the source IP address for outgoing HWTACACS packets
   - Setting the username format and traffic statistics units
   - Setting the DSCP priority for HWTACACS packets
9. (Optional.) Configuring HWTACACS stop-accounting packet buffering

Creating an HWTACACS scheme

Restrictions and guidelines

You can configure a maximum of 16 HWTACACS schemes. An HWTACACS scheme can be used by multiple ISP domains.

Procedure

1. Enter system view.

   system-view
2. Create an HWTACACS scheme and enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

Specifying the HWTACACS authentication servers

About this task

You can specify one primary authentication server and a maximum of 16 secondary authentication servers for an HWTACACS scheme. When the primary server is unreachable, the device searches

for the secondary servers in the order they are configured. The first secondary server in active state is used for communication.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

An HWTACACS server can function as the primary authentication server in one scheme and as the secondary authentication server in another scheme at the same time.

Two HWTACACS authentication servers in a scheme, primary or secondary, cannot have the same combination of VPN instance, host name, IP address, and port number.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify the primary HWTACACS authentication server.

   primary authentication { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no primary HWTACACS authentication server is specified.

4. (Optional.) Specify a secondary HWTACACS authentication server.

   secondary authentication { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no secondary HWTACACS authentication servers are specified.

Specifying the HWTACACS authorization servers

About this task

You can specify one primary authorization server and a maximum of 16 secondary authorization servers for an HWTACACS scheme. When the primary server is not available, the device searches for the secondary servers in the order they are configured. The first secondary server in active state is used for communication.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

An HWTACACS server can function as the primary authorization server of one scheme and as the secondary authorization server of another scheme at the same time.

Two HWTACACS authorization servers in a scheme, primary or secondary, cannot have the same combination of VPN instance, host name, IP address, and port number.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify the primary HWTACACS authorization server.

primary authorization { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

By default, no primary HWTACACS authorization server is specified.

4. (Optional.) Specify a secondary HWTACACS authorization server.

secondary authorization { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

By default, no secondary HWTACACS authorization servers are specified.

Specifying the HWTACACS accounting servers

About this task

You can specify one primary accounting server and a maximum of 16 secondary accounting servers for an HWTACACS scheme. When the primary server is not available, the device searches for the secondary servers in the order they are configured. The first secondary server in active state is used for communication.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

An HWTACACS server can function as the primary accounting server of one scheme and as the secondary accounting server of another scheme at the same time.

Two HWTACACS accounting servers in a scheme, primary or secondary, cannot have the same combination of VPN instance, host name, IP address, and port number.

HWTACACS does not support accounting for FTP, SFTP, and SCP users.

Procedure

1. Enter system view.

system-view

2. Enter HWTACACS scheme view.

hwtacacs scheme *hwtacacs-scheme-name*

3. Specify the primary HWTACACS accounting server.

primary accounting { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

By default, no primary HWTACACS accounting server is specified.

4. (Optional.) Specify a secondary HWTACACS accounting server.

secondary accounting { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

By default, no secondary HWTACACS accounting servers are specified.

Specifying the shared keys for secure HWTACACS communication

About this task

The HWTACACS client and server use the MD5 algorithm and shared keys to generate the Authenticator value for packet authentication and user password encryption. The client and server must use the same key for each type of communication.

Perform this task to configure shared keys for servers in an HWTACACS scheme. The keys take effect on all servers for which a shared key is not individually configured.

Restrictions and guidelines

Make sure the shared key configured on the device is the same as the shared key configured on the HWTACACS server.

Procedure

1. Enter system view.
   system-view
2. Enter HWTACACS scheme view.
   hwtacacs scheme *hwtacacs-scheme-name*
3. Specify a shared key for secure HWTACACS authentication, authorization, or accounting communication.
   key { **accounting** | **authentication** | **authorization** } { **cipher** | **simple** } *string*
   By default, no shared key is specified for secure HWTACACS communication.

Specifying an MPLS L3VPN instance for the scheme

About this task

The VPN instance specified for an HWTACACS scheme applies to all servers in that scheme. If a VPN instance is also configured for an individual HWTACACS server, the VPN instance specified for the HWTACACS scheme does not take effect on that server.

Procedure

1. Enter system view.
   system-view
2. Enter HWTACACS scheme view.
   hwtacacs scheme *hwtacacs-scheme-name*
3. Specify a VPN instance for the HWTACACS scheme.
   vpn-instance *vpn-instance-name*
   By default, an HWTACACS scheme belongs to the public network.

Setting HWTACACS timers

About this task

The device uses the following timers to control communication with an HWTACACS server:

- **Server response timeout timer (response-timeout)**—Defines the HWTACACS server response timeout timer. The device starts this timer immediately after an HWTACACS authentication, authorization, or accounting request is sent. If the device does not receive a

response from the server within the timer, it sets the server to blocked. Then, the device sends the request to another HWTACACS server.

- **Real-time accounting timer (realtime-accounting)**—Defines the intervals at which the device sends real-time accounting packets to the HWTACACS accounting server for online users.
- **Server quiet timer (quiet)**—Defines the duration to keep an unreachable server in blocked state. If a server is not reachable, the device changes the server status to blocked, starts this timer for the server, and tries to communicate with another server in active state. After the server quiet timer expires, the device changes the status of the server back to active.

The server quiet timer setting affects the status of HWTACACS servers. If the scheme includes one primary HWTACACS server and multiple secondary HWTACACS servers, the device communicates with the HWTACACS servers based on the following rules:

- When the primary server is in active state, the device communicates with the primary server. When the primary server is unreachable, the device researches a secondary server in active status in the order they are configured.
- When one or more servers are in active state, the device tries to communicate with these servers only, even if they are unreachable.
- When all servers are in blocked state, the device only tries to communicate with the primary server.
- If the primary server is unreachable, the device changes the server status to blocked and starts a quiet timer for the server. When the quiet timer of the server expires, the status of the server changes back to active. The device does not check the server again during the authentication, authorization, or accounting process.
- The search process continues until the device finds an available secondary server or has checked all secondary servers in active state. If no server is available, the device considers the authentication, authorization, or accounting attempt a failure.
- When you remove a server in use, communication with the server times out. The device looks for a server in active state by first checking the primary server, and then checking secondary servers in the order they are configured.
- When an HWTACACS server's status changes automatically, the device changes this server's status accordingly in all HWTACACS schemes in which this server is specified.

Restrictions and guidelines

A short real-time accounting interval helps improve accounting precision but requires many system resources. When there are 1000 or more users, set a real-time accounting interval longer than 15 minutes.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Set the HWTACACS timers. Choose the following tasks as needed:
   - Set the HWTACACS server response timeout timer.

     timer response-timeout *seconds*

     By default, the HWTACACS server response timeout timer is 5 seconds.
   - Set the real-time accounting interval.

     timer realtime-accounting *minutes*

     By default, the real-time accounting interval is 12 minutes.
   - Set the server quiet timer.

timer quiet *minutes*

By default, the server quiet timer is 5 minutes.

Specifying the source IP address for outgoing HWTACACS packets

About this task

The source IP address of HWTACACS packets that a NAS sends must match the IP address of the NAS configured on the HWTACACS server. An HWTACACS server identifies a NAS by IP address. When the HWTACACS server receives a packet, it checks the source IP address of the packet.

- If it is the IP address of a managed NAS, the server processes the packet.
- If it is not the IP address of a managed NAS, the server drops the packet.

Before sending an HWTACACS packet, the NAS selects a source IP address in the following order:

1. The source IP address specified for the HWTACACS scheme.
2. The source IP address specified in system view for the VPN or public network, depending on where the HWTACACS server resides.
3. The IP address of the outbound interface specified by the route.

Restrictions and guidelines for source IP address configuration

You can specify the source IP address for outgoing HWTACACS packets in HWTACACS scheme view or in system view.

- The IP address specified in HWTACACS scheme view applies to one HWTACACS scheme.
- The IP address specified in system view applies to all HWTACACS schemes.

The source IP address of HWTACACS packets that a NAS sends must match the IP address of the NAS that is configured on the HWTACACS server.

As a best practice, specify a loopback interface address as the source IP address for outgoing HWTACACS packets to avoid HWTACACS packet loss caused by physical port errors.

To communicate with the HWTACACS server, the source address of outgoing HWTACACS packets is typically the IP address of an egress interface on the NAS. However, in some situations, you must change the source IP address. For example, when VRRP is configured for stateful failover, configure the virtual IP of the uplink VRRP group as the source address.

You can directly specify a source IP address for outgoing HWTACACS packets or specify a source interface to provide the source IP address for outgoing HWTACACS packets. The source interface configuration and the source IP address configuration overwrite each other.

Specifying a source interface or source IP address for all HWTACACS schemes

1. Enter system view.

   system-view

2. Specify a source interface or source IP address for outgoing HWTACACS packets.

   hwtacacs nas-ip { **interface** *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] }

   By default, the source IP address of an HWTACACS packet sent to the server is the primary IPv4 address or the IPv6 address of the outbound interface.

Specifying a source interface or source IP address for an HWTACACS scheme

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify a source interface or source IP address for outgoing HWTACACS packets.

   nas-ip { *ipv4-address* | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, the source IP address of an outgoing HWTACACS packet is that configured by using the **hwtacacs nas-ip** command in system view. If the **hwtacacs nas-ip** command is not used, the source IP address is the primary IP address of the outbound interface.

Setting the username format and traffic statistics units

About this task

A username is typically in the *userid@isp-name* format, where the *isp-name* part represents the user's ISP domain name. By default, the ISP domain name is included in a username. If HWTACACS servers do not recognize usernames that contain ISP domain names, you can configure the device to send usernames without domain names to the servers.

The device reports online user traffic statistics in accounting packets.

Restrictions and guidelines

If two or more ISP domains use the same HWTACACS scheme, configure the HWTACACS scheme to keep the ISP domain name in usernames for domain identification.

For accounting accuracy, make sure the traffic measurement units configured on the device are the same as the traffic measurement units configured on the HWTACACS accounting servers.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Set the format of usernames sent to the HWTACACS servers.

   user-name-format { **keep-original** | **with-domain** | **without-domain** }

   By default, the ISP domain name is included in a username.

4. Set the data flow and packet measurement units for traffic statistics.

   data-flow-format { **data** { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** } | **packet** { **giga-packet** | **kilo-packet** | **mega-packet** | **one-packet** } }*

   By default, traffic is counted in bytes and packets.

Setting the DSCP priority for HWTACACS packets

About this task

DSCP priority determines the transmission priority of HWTACACS packets. A larger value represents a higher priority.

DSCP priority is contained in the ToS field of the IPv4 header and in the Traffic Class field of the IPv6 header.

Procedure

1. Enter system view.

   system-view

2. Set the DSCP priority for HWTACACS packets.

   hwtacacs [**ipv6**] **dscp** *dscp-value*

   By default, the DSCP priority is 0 for HWTACACS packets.

Configuring HWTACACS stop-accounting packet buffering

About this task

The device sends HWTACACS stop-accounting requests when it receives connection teardown requests from hosts or connection teardown commands from an administrator. However, the device might fail to receive a response for a stop-accounting request in a single transmission. Enable the device to buffer HWTACACS stop-accounting requests that have not received responses from the accounting server. The device will resend the requests until responses are received.

To limit the transmission times, set a maximum number of attempts that can be made for transmitting individual HWTACACS stop-accounting requests. When the maximum attempts are made for a request, the device discards the buffered request.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Enable buffering of HWTACACS stop-accounting requests to which no responses have been received.

   stop-accounting-buffer enable

   By default, the buffering feature is enabled.

4. (Optional.) Set the maximum number of transmission attempts for individual HWTACACS stop-accounting requests.

   retry stop-accounting *retries*

   The default setting is 100.

Enabling SNMP notifications for HWTACACS

About this task

When SNMP notifications are enabled for HWTACACS, the SNMP agent supports the following notifications generated by HWTACACS:

- **HWTACACS server unreachable notification**—The HWTACACS server cannot be reached. The NAS generates this notification if it does not receive a response to an accounting, authentication, or authorization request within the specified number of HWTACACS request transmission attempts.
- **HWTACACS server reachable notification**—The HWTACACS server can be reached. The NAS generates this notification for a previously blocked HWTACACS server after the quiet timer expires and sets the server status to active.

For HWTACACS SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for HWTACACS.

   snmp-agent trap enable hwtacacs [**accounting-server-down** | **accounting-server-up** | **authentication-server-down** | **authentication-server-up** | **authorization-server-down** | **authorization-server-up**] *

   By default, all types of SNMP notifications for HWTACACS are disabled.

Display and maintenance commands for HWTACACS

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the configuration or server statistics of HWTACACS schemes.	**display hwtacacs scheme** [*hwtacacs-scheme-name* [**statistics**]]
Display information about buffered HWTACACS stop-accounting requests to which no responses have been received.	**display stop-accounting-buffer hwtacacs-scheme** *hwtacacs-scheme-name*
Display HWTACACS packet statistics.	**display hwtacacs statistics**
Clear HWTACACS statistics.	**reset hwtacacs statistics** { **accounting** | **all** | **authentication** | **authorization** }
Clear the buffered HWTACACS stop-accounting requests to which no responses have been received.	**reset stop-accounting-buffer hwtacacs-scheme** *hwtacacs-scheme-name*

Configuring LDAP

LDAP tasks at a glance

To configure LDAP, perform the following tasks:

1. Configuring an LDAP server
   a. Creating an LDAP server
   b. Configuring the IP address of the LDAP server
   c. (Optional.) Specifying the LDAP version
   d. (Optional.) Setting the LDAP server timeout period
   e. Configuring administrator attributes
   f. Configuring LDAP user attributes
2. (Optional.) Configuring an LDAP attribute map
3. Creating an LDAP scheme
4. Specifying the LDAP authentication server
5. (Optional.) Specifying the LDAP authorization server
6. (Optional.) Specifying an LDAP attribute map for LDAP authorization

Creating an LDAP server

1. Enter system view.

system-view

2. Create an LDAP server and enter LDAP server view.
   ldap server *server-name*

Configuring the IP address of the LDAP server

Restrictions and guidelines

You can configure either an IPv4 address or an IPv6 address for an LDAP server. If you configure the IP address for an LDAP server multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.
   system-view
2. Enter LDAP server view.
   ldap server *server-name*
3. Configure the IP address of the LDAP server.
   { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]
   By default, an LDAP server does not have an IP address.

Specifying the LDAP version

Restrictions and guidelines

The device supports LDAPv2 and LDAPv3.

A Microsoft LDAP server supports only LDAPv3.

The LDAP version specified on the device must be consistent with the version specified on the LDAP server.

Procedure

1. Enter system view.
   system-view
2. Enter LDAP server view.
   ldap server *server-name*
3. Specify the LDAP version.
   protocol-version { **v2** | **v3** }
   By default, LDAPv3 is used.

Setting the LDAP server timeout period

About this task

If the device sends a bind or search request to an LDAP server without receiving the server's response within the server timeout period, the authentication or authorization request times out. Then, the device tries the backup authentication or authorization method. If no backup method is configured in the ISP domain, the device considers the authentication or authorization attempt a failure.

Procedure

1. Enter system view.

system-view

2. Enter LDAP server view.

   ldap server *server-name*

3. Set the LDAP server timeout period.

   server-timeout *time-interval*

   By default, the LDAP server timeout period is 10 seconds.

Configuring administrator attributes

About this task

To configure the administrator DN and password for binding with the LDAP server during LDAP authentication:

Procedure

1. Enter system view.

   system-view

2. Enter LDAP server view.

   ldap server *server-name*

3. Specify the administrator DN.

   login-dn *dn-string*

   By default, no administrator DN is specified.

   The administrator DN specified on the device must be the same as the administrator DN configured on the LDAP server.

4. Configure the administrator password.

   login-password { **cipher** | **simple** } *string*

   By default, no administrator password is specified.

Configuring LDAP user attributes

About this task

To authenticate a user, an LDAP client must complete the following operations:

1. Establish a connection to the LDAP server.
2. Obtain the user DN from the LDAP server.
3. Use the user DN and the user's password to bind with the LDAP server.

LDAP provides a DN search mechanism for obtaining the user DN. According to the mechanism, an LDAP client sends search requests to the server based on the search policy determined by the LDAP user attributes of the LDAP client.

The LDAP user attributes include:

- Search base DN.
- Search scope.
- Username attribute.
- Username format.
- User object class.

Restrictions and guidelines

If the LDAP server contains many directory levels, a user DN search starting from the root directory can take a long time. To improve efficiency, you can change the start point by specifying the search base DN.

Procedure

1. Enter system view.
   system-view
2. Enter LDAP server view.
   ldap server *server-name*
3. Specify the user search base DN.
   search-base-dn *base-dn*
   By default, no user search base DN is specified.
4. (Optional.) Specify the user search scope.
   search-scope { **all-level** | **single-level** }
   By default, the user search scope is **all-level**.
5. (Optional.) Specify the username attribute.
   user-parameters user-name-attribute { *name-attribute* | **cn** | **uid** }
   By default, the username attribute is **cn**.
6. (Optional.) Specify the username format.
   user-parameters user-name-format { **with-domain** | **without-domain** }
   By default, the username format is **without-domain**.
7. (Optional.) Specify the user object class.
   user-parameters user-object-class *object-class-name*
   By default, no user object class is specified, and the default user object class on the LDAP server is used. The default user object class for this command varies by server model.

Configuring an LDAP attribute map

About this task

Configure an LDAP attribute map to define a list of LDAP-AAA attribute mapping entries. To apply the LDAP attribute map, specify the name of the LDAP attribute map in the LDAP scheme used for authorization.

The LDAP attribute map feature enables the device to convert LDAP attributes obtained from an LDAP authorization server to device-recognizable AAA attributes based on the mapping entries. Because the device ignores unrecognized LDAP attributes, configure the mapping entries to include important LDAP attributes that should not be ignored.

An LDAP attribute can be mapped only to one AAA attribute. Different LDAP attributes can be mapped to the same AAA attribute.

Procedure

1. Enter system view.
   system-view
2. Create an LDAP attribute map and enter LDAP attribute map view.
   ldap attribute-map *map-name*
3. Configure a mapping entry.

map ldap-attribute *ldap-attribute-name* [**prefix** *prefix-value* **delimiter** *delimiter-value*] **aaa-attribute user-group**

Creating an LDAP scheme

Restrictions and guidelines

You can configure a maximum of 16 LDAP schemes. An LDAP scheme can be used by multiple ISP domains.

Procedure

1. Enter system view.
   system-view
2. Create an LDAP scheme and enter LDAP scheme view.
   ldap scheme *ldap-scheme-name*

Specifying the LDAP authentication server

1. Enter system view.
   system-view
2. Enter LDAP scheme view.
   ldap scheme *ldap-scheme-name*
3. Specify the LDAP authentication server.
   authentication-server *server-name*
   By default, no LDAP authentication server is specified.

Specifying the LDAP authorization server

1. Enter system view.
   system-view
2. Enter LDAP scheme view.
   ldap scheme *ldap-scheme-name*
3. Specify the LDAP authorization server.
   authorization-server *server-name*
   By default, no LDAP authorization server is specified.

Specifying an LDAP attribute map for LDAP authorization

About this task

Specify an LDAP attribute map for LDAP authorization to convert LDAP attributes obtained from the LDAP authorization server to device-recognizable AAA attributes.

Restrictions and guidelines

You can specify only one LDAP attribute map in an LDAP scheme.

Procedure

1. Enter system view.
   system-view

2. Enter LDAP scheme view.
   ldap scheme *ldap-scheme-name*
3. Specify an LDAP attribute map.
   attribute-map *map-name*
   By default, no LDAP attribute map is specified.

Display and maintenance commands for LDAP

Execute **display** commands in any view.

Task	Command
Display the configuration of LDAP schemes.	**display ldap scheme** [*ldap-scheme-name*]

Creating an ISP domain

About ISP domains

In a networking scenario with multiple ISPs, the device can connect to users of different ISPs. These users can have different user attributes, such as different username and password structures, different service types, and different rights. To manage users of different ISPs, configure authentication, authorization, and accounting methods and domain attributes for each ISP domain as needed.

The device supports a maximum of 16 ISP domains, including the system-defined ISP domain **system**. You can specify one of the ISP domains as the default domain.

On the device, each user belongs to an ISP domain. If a user does not provide an ISP domain name at login, the device considers the user belongs to the default ISP domain.

Each ISP domain has a set of system-defined AAA methods, which are local authentication, local authorization, and local accounting. If you do not configure any AAA methods for an ISP domain, the device uses the system-defined AAA methods for users in the domain.

The device chooses an authentication domain for each user in the following order:

1. The authentication domain specified for the access module.
2. The ISP domain in the username.
3. The default ISP domain of the device.

If the chosen domain does not exist on the device, the device searches for the ISP domain that accommodates users assigned to nonexistent domains. (Support for the authentication domain configuration depends on the access module.) If no such ISP domain is configured, user authentication fails.

Restrictions and guidelines for ISP domain configuration

An ISP domain cannot be deleted when it is the default ISP domain. Before you use the **undo domain** command, change the domain to a non-default ISP domain by using the **undo domain default enable** command.

You can modify the settings of the system-defined ISP domain **system**, but you cannot delete the domain.

To avoid RADIUS authentication, authorization, or accounting failures, use short domain names to ensure that usernames containing a domain name do not exceed 253 characters.

To avoid RADIUS accounting failures, make sure the domain name contained in usernames sent to the RADIUS server does not exceed 247 characters.

Creating an ISP domain

1. Enter system view.
   system-view
2. Create an ISP domain and enter ISP domain view.
   domain *isp-name*
   By default, a system-defined ISP domain exists. The domain name is **system**.

Specifying the default ISP domain

1. Enter system view.
   system-view
2. Specify the default ISP domain.
   domain default enable *isp-name*
   By default, the default ISP domain is the system-defined ISP domain **system**.

Specifying an ISP domain for users that are assigned to nonexistent domains

1. Enter system view.
   system-view
2. Specify the ISP domain to accommodate users that are assigned to nonexistent domains.
   domain if-unknown *isp-name*
   By default, no ISP domain is specified to accommodate users that are assigned to nonexistent domains.

Configuring ISP domain attributes

Setting ISP domain status

About this task

By placing the ISP domain in active or blocked state, you allow or deny network service requests from users in the domain.

Procedure

1. Enter system view.
   system-view
2. Enter ISP domain view.
   domain *isp-name*
3. Set the status of the ISP domain.
   state { **active** | **block** }

By default, an ISP domain is in active state, and users in the domain can request network services.

Configuring an authorization profile

About this task

An authorization profile defines a set of authorization attributes and can be used to authorize network resources on a VPN basis, for example, assigning different microsegments to different VPN users. If you apply an authorization profile to an authentication domain, all users in the domain can obtain network resources defined in the profile.

Restrictions and guidelines

Authorization profiles take effect only on 802.1X, MAC, and Web authentication users.

You can configure a maximum of 16 authorization profiles.

Deleting or changing an authorization profile does not affect users that are using the profile. The configuration change takes effect only on new clients that come online afterward.

Procedure

1. Enter system view.

   system-view

2. Create an authorization profile and enter its view.

   aaa author-profile *profile-name*

3. Specify a VPN instance and microsegment binding.

   if-match vpn-instance *vpn-instance-name* **microsegment** *microsegment-id* [**vsi** *vsi-name*]

   By default, no VPN instance and microsegment binding is specified.

   You can bind a VPN instance only to one microsegment but a microsegment to multiple VPN instances.

4. Specify the default microsegment.

   default microsegment *microsegment-id* [**vsi** *vsi-name*]

   By default, no default microsegment exists.

   The system authorizes the default microsegment to non-VPN users and VPN users that do not match any VPN instance specified by the **if-match vpn-instance microsegment** command.

Configuring authorization attributes for an ISP domain

About this task

The device supports the following authorization attributes:

- **ACL**—The device restricts authenticated users to access only the network resources permitted by the ACL.
- **Idle cut**—The device logs out a user if the user's total traffic in the idle timeout period at the specified direction is less than the specified minimum traffic.
- **Maximum number of multicast groups**—The attribute restricts the maximum number of multicast groups that an authenticated user can join concurrently.
- **IPv4 address pool**—The device assigns IPv4 addresses from the pool to authenticated users in the domain.

- **IPv6 address pool**—The device assigns IPv6 addresses from the pool to authenticated users in the domain.
- **Microsegment**—The device authorizes the authenticated users to access the network resources in the specified microsegment.
- **Redirect URL**—The device redirects users in the domain to the URL after they pass authentication.
- **User group**—Authenticated users in the domain obtain all attributes of the user group.
- **VLAN**—The device authorizes the authenticated users to access the network resources in the specified VLAN.
- **VSI**—The device authorizes the authenticated users to access the network resources in the specified VSI.

Restrictions and guidelines

To avoid user logoff caused by authorization attribute conflicts, do not assign an authorization VSI and an authorization VLAN at the same time. The conflict occurs in the following cases:

- The server authorizes a VSI through session control or CoA messages to an online user that is authorized with a VLAN at association.
- The server authorizes a VLAN through session control or CoA messages to an online user that is authorized with a VSI at association.
- The server authorizes a VSI through session control or CoA messages to an online user that uses the default authorization VLAN because no VLAN or VSI is authorized at association.

When you specify matching rules for user terminals, follow these restrictions and guidelines:

- Vertical bars (|) are used as the delimiter in matching rules and cannot be input as part of a rule.
- Do not input vertical bars (|) consecutively, such as ||, |||, or | |.
- Matching rules can include spaces, but spaces do not participate in the match and will occupy string length.

Procedure

1. Enter system view.

   system-view

2. Enter ISP domain view.

   domain *isp-name*

3. Configure authorization attributes for authenticated users in the ISP domain.

   authorization-attribute { **acl** *acl-number* | **author-profile** *profile-name* | **idle-cut** *minutes* [*flow*] [**traffic** { **both** | **inbound** | **outbound** }] | **igmp max-access-number** *max-access-number* | **ip-pool** *ipv4-pool-name* | **ipv6-pool** *ipv6-pool-name* | **microsegment** *microsegment-id* | **mld max-access-number** *max-access-number* | **session-group-profile** *session-group-profile-name* | **redirect** { **deny** | **permit** } **user-agent match** *match-string* | **url** *url-string* | **user-group** *user-group-name* | **vlan** *vlan-id* | **vsi** *vsi-name* }

   The default settings are as follows:

   - The idle cut feature is disabled.
   - An IPv4 user can concurrently join a maximum of four IGMP multicast groups.
   - An IPv6 user can concurrently join a maximum of four MLD multicast groups.
   - No other authorization attributes exist.

Including the idle timeout period in the user online duration to be sent to the server

About this task

If a user goes offline due to connection failure or malfunction, the user's online duration sent to the server includes the idle timeout period assigned by the authorization server. The online duration generated on the server is longer than the actual online duration of the user.

For portal users, the device includes the idle timeout period set for the online portal user detection feature in the user online duration. For more information about online detection for portal users, see "Configuring portal authentication."

Procedure

1. Enter system view.
   `system-view`
2. Enter ISP domain view.
   `domain` *`isp-name`*
3. Configure the device to include the idle timeout period in the user online duration to be sent to the server.
   `session-time include-idle-time`
   By default, the user online duration sent to the server does not include the idle timeout period.

Enabling temporary redirect

About this task

Typically, the device carries the redirect URL coded in JavaScript in HTTP or HTTPS responses sent to users, and the status code in the responses is 200. The users obtain the redirect URL by parsing the JavaScript codes. If the endpoint of a user (application, for example) does not support JavaScript, the user will fail to be redirected.

To resolve this issue, enable the temporary redirect feature. This feature enables the device to send HTTP or HTTPS responses with status code 302 to users so that the users can obtain the redirect URL.

Restrictions and guidelines

As a best practice, enable this feature only when users that do not support decoding Java Script in HTTP/HTTPS packets exist in the network.

This feature takes effect only on wired 802.1X and MAC authentication users authorized with a redirection URL.

If you change the temporary redirect setting, the change takes effect only on users that come online afterwards or users that are reauthorized.

Procedure

1. Enter system view.
   `system-view`
2. Enter ISP domain view.
   `domain` *`isp-name`*
3. Enable temporary redirect.
   `redirect move-temporarily enable`
   By default, temporary redirect is disabled.

Specifying the user address type in an ISP domain

1. Enter system view.
   system-view
2. Enter ISP domain view.
   domain *isp-name*
3. Specify the user address type in the ISP domain.
   user-address-type { **ds-lite** | **ipv6** | **nat64** | **private-ds** | **private-ipv4** | **public-ds** | **public-ipv4** }
   By default, no user address type is specified.

Configuring the authentication failure policy for users in an ISP domain

About this task

By default, users cannot come online if they fail authentication. To have authentication-failed users in an authentication domain stay online and access a limited set of network resources, specify an auth-fail domain to accommodate them. In the auth-fail domain, you can specify a set of authorization and accounting schemes to assign resources to the authentication-failed users.

Restrictions and guidelines

The authen-fail online feature is applicable only to wired 802.1X, Web authentication, and MAC authentication users.

The authen-fail online feature does not apply to users that fail authentication for one of the following reasons:

- Authentication times out, for example, because no authentication servers respond or no matching local users are found.
- The authentication domain is in blocked state or is a denied domain.

Procedure

1. Enter system view.
   system-view
2. Enter ISP domain view.
   domain *isp-name*
3. Configure the authentication failure policy for users in the ISP domain.
   authen-fail { **offline** | **online domain** *new-isp-name* **no-authen** }
   By default, the device logs out users in an ISP domain if the users fail authentication.

Configuring AAA methods for an ISP domain

Configuring authentication methods for an ISP domain

Restrictions and guidelines

When you configure remote authentication, follow these restrictions and guidelines:

- For high availability, you can specify one primary authentication method and multiple backup authentication methods. When the primary method is invalid, the device attempts to use the

backup methods in sequence. For example, the **radius-scheme** *radius-scheme-name* **local none** parameters specify a primary RADIUS authentication method and two backup methods (local authentication and no authentication). The device performs RADIUS authentication by default and performs local authentication when the RADIUS server is invalid. The device does not perform authentication when both of the previous methods are invalid.

The remote authentication method is invalid in the following situations:

- The specified authentication scheme does not exist.
- The device fails to send authentication request packets.
- The device does not receive any authentication response packets from an authentication server.

The local authentication method is invalid if the device fails to find the matching local user configuration.

- If the authentication method uses a RADIUS scheme and the authorization method does not use a RADIUS scheme, AAA accepts only the authentication result from the RADIUS server. The Access-Accept message from the RADIUS server also includes the authorization information, but the device ignores the information.
- If an HWTACACS scheme is specified, the device uses the entered username for role authentication. If a RADIUS scheme is specified, the device uses username **$enab***n***$** on the RADIUS server for role authentication. The variable *n* represents a user role level. For more information about user role authentication, see *Fundamentals Configuration Guide*.

The **none** keyword is not supported in FIPS mode.

When the primary authentication method is local, the following rules apply to the authentication of a user:

- The device uses the backup authentication methods in sequence only if local authentication is invalid for one of the following reasons:
  - An exception occurs in the local authentication process.
  - The device connection is terminated or the user account is not configured on the device.
- The device does not turn to the backup authentication methods if local authentication is invalid because of any other reason. Authentication fails for the user.

Prerequisites

Before configuring authentication methods, complete the following tasks:

1. Determine the access type or service type to be configured. With AAA, you can configure an authentication method for each access type and service type.
2. Determine whether to configure the default authentication method for all access types or service types. The default authentication method applies to all access users. However, the method has a lower priority than the authentication method that is specified for an access type or service type.

Procedure

1. Enter system view.

   system-view

2. Enter ISP domain view.

   domain *isp-name*

3. (Optional.) Specify default authentication methods for all types of users.

   authentication default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **local** [**ldap-scheme** *ldap-scheme-name*] | **none** | **radius-scheme**

radius-scheme-name [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

By default, the default authentication method is **local**.

4. Specify authentication methods for a user type or a service.
   - Specify authentication methods for LAN users.

     authentication lan-access { **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**ldap-scheme** *ldap-scheme-name* | **radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default authentication methods are used for LAN users.
   - Specify authentication methods for login users.

     authentication login { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **local** [**ldap-scheme** *ldap-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

     By default, the default authentication methods are used for login users.
   - Specify authentication methods for portal users.

     authentication portal { **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**ldap-scheme** *ldap-scheme-name* | **radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default authentication methods are used for portal users.
   - Specify authentication methods for obtaining a temporary user role.

     authentication super { **hwtacacs-scheme** *hwtacacs-scheme-name* | **radius-scheme** *radius-scheme-name* } *

     By default, the default authentication methods are used for obtaining a temporary user role.

Configuring authorization methods for an ISP domain

Restrictions and guidelines

For high availability, you can specify one primary authorization method and multiple backup authorization methods. When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **radius-scheme** *radius-scheme-name* **local none** parameters specify a primary RADIUS authorization method and two backup methods (local authorization and no authorization). The device performs RADIUS authorization by default and performs local authorization when the RADIUS server is invalid. The device does not perform authorization when both of the previous methods are invalid.

The remote authorization method is invalid in the following situations:

- The specified authorization scheme does not exist.
- The device fails to send authorization request packets.
- The device does not receive any authorization response packets from an authorization server.

The local authorization method is invalid if the device fails to find the matching local user configuration.

Only SSL VPN users support LDAP authorization in the current software version.

To use a RADIUS scheme as the authorization method, specify the name of the RADIUS scheme that is configured as the authentication method for the ISP domain. If an invalid RADIUS scheme is specified as the authorization method, RADIUS authentication and authorization fail.

The **none** keyword is not supported in FIPS mode.

When the primary authorization method is local, the following rules apply:

- The device uses the backup authorization methods in sequence only if local authorization is invalid for one of the following reasons:
  - An exception occurs in the local authorization process.
  - The device connection is terminated or the user account is not configured on the device
- The device does not turn to the backup authorization methods if local authorization is invalid because of any other reason. Authorization fails for the user.

Prerequisites

Before configuring authorization methods, complete the following tasks:

1. Determine the access type or service type to be configured. With AAA, you can configure an authorization scheme for each access type and service type.
2. Determine whether to configure the default authorization method for all access types or service types. The default authorization method applies to all access users. However, the method has a lower priority than the authorization method that is specified for an access type or service type.

Procedure

1. Enter system view.

   system-view

2. Enter ISP domain view.

   domain *isp-name*

3. (Optional.) Specify default authorization methods for all types of users.

   authorization default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

   By default, the authorization method is **local**.

4. Specify authorization methods for a user type or a service.
   - Specify command authorization methods.

     authorization command { **hwtacacs-scheme** *hwtacacs-scheme-name* [**local**] [**none**] | **local** [**none**] | **none** }

     By default, the default authorization methods are used for command authorization.
   - Specify authorization methods for LAN users.

     authorization lan-access { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default authorization methods are used for LAN users.
   - Specify authorization methods for login users.

     authorization login { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **none** | **radius-scheme**

radius-scheme-name [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

By default, the default authorization methods are used for login users.

- Specify authorization methods for portal users.

  authorization portal { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

  By default, the default authorization methods are used for portal users.

Configuring accounting methods for an ISP domain

Restrictions and guidelines

For high availability, you can specify one primary accounting method and multiple backup accounting methods. When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **radius-scheme** *radius-scheme-name* **local none** parameters specify a primary RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

The remote accounting method is invalid in the following situations:

- The specified accounting scheme does not exist.
- The device fails to send accounting request packets.
- The device does not receive any accounting response packets from an accounting server.

The local accounting method is invalid if the device fails to find the matching local user configuration.

FTP, SFTP, and SCP users do not support accounting.

Local accounting does not provide statistics for charging. It only counts and controls the number of concurrent users that use the same local user account. The threshold is configured by using the **access-limit** command.

The **none** keyword is not supported in FIPS mode.

When the primary accounting method is local, the following rules apply:

- The device uses the backup accounting methods in sequence only if local accounting is invalid for one of the following reasons:
  - An exception occurs in the local accounting process.
  - The device connection is terminated or the user account is not configured on the device
- The device does not turn to the backup accounting methods if local accounting is invalid because of any other reason. Accounting fails for the user.

Prerequisites

Before configuring accounting methods, complete the following tasks:

1. Determine the access type or service type to be configured. With AAA, you can configure an accounting method for each access type and service type.
2. Determine whether to configure the default accounting method for all access types or service types. The default accounting method applies to all access users. However, the method has a lower priority than the accounting method that is specified for an access type or service type.

Procedure

1. Enter system view.

   system-view
2. Enter ISP domain view.

domain *isp-name*

3. (Optional.) Specify default accounting methods for all types of users.

   accounting default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

   By default, the accounting method is **local**.

4. Specify accounting methods for a user type.
   - Specify the command accounting method.

     accounting command hwtacacs-scheme *hwtacacs-scheme-name*

     By default, the default accounting methods are used for command accounting.
   - Specify accounting methods for LAN users.

     accounting lan-access { **broadcast radius-scheme** *radius-scheme-name1* **radius-scheme** *radius-scheme-name2* [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default accounting methods are used for LAN users.
   - Specify accounting methods for login users.

     accounting login { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name* | **hwtacacs-scheme** *hwtacacs-scheme-name*] * [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

     By default, the default accounting methods are used for login users.
   - Specify accounting methods for portal users.

     accounting portal { **broadcast radius-scheme** *radius-scheme-name1* **radius-scheme** *radius-scheme-name2* [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default accounting methods are used for portal users.

5. (Optional.) Configure extended accounting policies.
   - Configure access control for users that encounter accounting-start failures.

     accounting start-fail { **offline** | **online** }

     By default, the device allows users that encounter accounting-start failures to stay online.
   - Configure access control for users that have failed all their accounting-update attempts.

     accounting update-fail { [**max-times** *max-times*] **offline** | **online** }

     By default, the device allows users that have failed all their accounting-update attempts to stay online.
   - Configure access control for users that have used up their data or time accounting quotas.

     accounting quota-out { **offline** | **online** }

     By default, the device logs off users that have used up their accounting quotas.

Display and maintenance commands for ISP domains

Execute **display** commands in any view.

Task	Command
Display configuration information about an ISP domain or all ISP domains.	**display domain** [*isp-name*]

Configuring a critical profile

About this task

During authentication, if all authentication servers in the authentication scheme are unreachable, the device will not receive authentication responses from the server and users will fail authentication.

To resolve this issue, you can configure a critical profile and apply the profile to a port to accommodate the users when all authentication servers are unreachable. The users in a critical profile can access only network resources in the critical profile, such as the critical microsegment. For users in a VPN instance, the users can access the critical microsegment specified for the VPN instance. If no critical microsegment is specified for the VPN instance, the users can access the default critical microsegment.

Restrictions and guidelines

This feature is applicable only to 802.1X and MAC authentication users.

If you remove a critical profile from a port or edit the configuration in the critical profile, the change does not take effect on users already in the critical profile.

Procedure

1. Enter system view.

   system-view
2. Create a critical profile and enter its view.

   aaa critical-profile *profile-name*
3. Specify the default critical microsegment.

   default critical-microsegment *microsegment-id* [**vsi** *vsi-name*] [**url-user-logoff**]

   The **url-user-logoff** keyword is applicable only to MAC authentication users.
4. Specify the critical microsegment for a VPN instance.

   if-match vpn-instance *vpn-instance-name* **critical-microsegment** *microsegment-id* [**vsi** *vsi-name*] [**url-user-logoff**]

   By default, no critical microsegment is specified for a VPN instance.

   The **url-user-logoff** keyword is applicable only to MAC authentication users.

Configuring AAA fail-permit and recovery

About this task

This feature is used to resolve the issue that users cannot come online when all RADIUS servers are unavailable. The feature contains the following settings in a user authentication domain:

- In the user authentication domain, specify a critical domain (also known as fail-permit domain) to accommodate users that access the authentication domain when all RADIUS servers are unavailable. The users can come online in the critical domain without being authenticated when all RADIUS servers are unavailable.
- In the user authentication domain, specify an action to take on users that have been assigned to the critical domain when a RADIUS server becomes available.

- To perform authentication, authorization, and accounting for the users, log off the users.
- To allow the users to stay online without being authenticated, specify a recovery domain. When a RADIUS server becomes available, the users in the critical domain are assigned to the recovery domain.
- To reauthenticate users in the original authentication domain without users being aware of the process, specify the reauthentication action.

For the device to obtain the status of RADIUS authentication servers in time, it detects the status of the RADIUS authentication servers in each RADIUS scheme at intervals. In addition, the device notifies access modules to remove users that use a RADIUS scheme from the critical domain when that RADIUS scheme has reachable RADIUS servers.

Restrictions and guidelines

This feature takes effect only on the 802.1X authentication, Web authentication, and MAC authentication for wired users.

When you specify a critical domain for an ISP domain, follow these restrictions and guidelines:

- If non-none authentication, authorization, or accounting methods are configured in the critical domain for an ISP domain, the non-none authentication or authorization methods cannot take effect on users. However, the non-none accounting methods in the critical domain can take effect on users.
- If an ISP domain has been specified as a critical domain, do not specify a critical domain for that ISP domain. If you do so, the critical domain specified for that ISP domain cannot take effect.
- If a critical domain has been specified for an ISP domain, do not specify that ISP domain as a critical domain. If you do so, that ISP domain cannot act as a critical domain.

When you specify a recovery domain for an ISP domain, follow these restrictions and guidelines:

- If the **none** method is configured as the backup authentication method in the original authentication domain before the users are assigned to the critical domain, the users are still assigned to the recovery domain when a RADIUS server becomes available.
- As a best practice to accurately identify whether a RADIUS authentication server is available and the recovery configuration can take effect in time, configure RADIUS server status detection.
- In the current software version, you can specify only an ISP domain as its own recovery domain in the view of the ISP domain.

When you set the interval at which the device detects the status of RADIUS authentication servers, follow these restrictions and guidelines:

- A too short interval consumes too many system resources for access services. A too long interval cannot detect server status changes in time.
- As a best practice, consider the processing efficiency for access services and the accuracy for fail-permit and recovery when a large number of users come online in a short time.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Set the interval at which the device detects the status of RADIUS authentication servers.

   radius-server authen-state-check interval *interval*

   By default, the device detects the status of RADIUS authentication servers at intervals of 10 minutes.

3. Enter ISP domain view.

   domain *isp-name*

4. Specify a critical domain to accommodate users that access the ISP domain when all RADIUS servers are unavailable.

   authen-radius-unavailable online domain *new-isp-name*

   By default, no critical domain is specified for an ISP domain to accommodate users that access the ISP domain when all RADIUS servers are unavailable.

5. Specify an action to take on users in the critical domain when a RADIUS server becomes available.

   authen-radius-recover { **offline** | **online domain** *new-isp-name* | **re-authen** }

   By default, no action is specified for users in the critical domain when a RADIUS server becomes available.

Setting the maximum number of concurrent login users

About this task

Perform this task to set the maximum number of concurrent users that can log on to the device through a specific protocol, regardless of their authentication methods. The authentication methods include no authentication, local authentication, and remote authentication.

Procedure

1. Enter system view.

   system-view

2. Set the maximum number of concurrent login users.

   In non-FIPS mode:

   aaa session-limit { **ftp** | **http** | **https** | **ssh** | **telnet** } *max-sessions*

   In FIPS mode:

   aaa session-limit { **https** | **ssh** } *max-sessions*

   By default, the maximum number of concurrent login users is 32 for each user type.

Configuring a NAS-ID

About this task

During RADIUS authentication, the device uses a NAS-ID to set the NAS-Identifier attribute of RADIUS packets so that the RADIUS server can identify the access location of users.

The device selects the NAS-ID for the NAS-Identifier attribute in the following order:

1. NAS-ID in a VSRP instance. For more information, see VSRP configuration in *High Availability Configuration Guide*.
2. NAS-ID bound with VLANs in a NAS-ID profile.

If no NAS-ID is configured, the device uses the device name (set by using the **sysname** command) as the NAS-ID.

Configure a NAS-ID profile to maintain NAS-ID and VLAN bindings on the device so that the device can send different NAS-Identifier attribute strings in RADIUS requests from different VLANs.

Restrictions and guidelines

You can apply a NAS-ID profile to portal- or port security-enabled interfaces. For more information, see "Configuring portal authentication" and "Configuring port security."

You can configure multiple NAS-ID and VLAN bindings in a NAS-ID profile.

A NAS-ID can be bound with more than one VLAN, but a VLAN can be bound with only one NAS-ID. If you configure multiple bindings for the same VLAN, the most recent configuration takes effect.

Procedure

1. Enter system view.
   system-view
2. Create a NAS-ID profile and enter NAS-ID profile view.
   aaa nas-id profile *profile-name*
3. Configure a NAS-ID and VLAN binding in the profile.
   nas-id *nas-identifier* **bind vlan** *vlan-id*

Configuring the device ID

About this task

RADIUS uses the value of the Acct-Session-ID attribute as the accounting ID for a user. The device generates an Acct-Session-ID value for each online user based on the system time, random digits, and device ID.

Restrictions and guidelines

On a VSRP network where multiple devices use the same accounting server, accounting ID conflicts might occur. To avoid duplicate accounting IDs, perform this task to assign a unique device ID to each device.

Procedure

1. Enter system view.
   system-view
2. Configure the device ID.
   aaa device-id *device-id*

   By default, the device ID is 0.

Enabling password change prompt logging

About this task

Use this feature to enhance the protection of passwords for Telnet, SSH, HTTP, HTTPS, NETCONF over SSH, and NETCONF over SOAP users and improve the system security.

This feature enables the device to generate logs to prompt users to change their weak passwords at an interval of 24 hours and at the users' login.

A password is a weak password if it does not meet the following requirements:

- Password composition restriction configured by using the **password-control composition** command.
- Minimum password length restriction set by using the **password-control length** command.
- Password complexity checking policy configured by using the **password-control complexity** command.

For a NETCONF over SSH or NETCONF over SOAP user, the device also generates a password change prompt log if any of the following conditions exists:

- The current password of the user is the default password or has expired.
- The user logs in to the device for the first time or uses a new password to log in after global password control is enabled.

The device will no longer generate password change prompt logs for a user when one of the following conditions exists:

- The password change prompt logging feature is disabled.
- The user has changed the password and the new password meets the password control requirements.
- The enabling status of a related password control feature has changed so the current password of the user meets the password control requirements.
- The password composition policy or the minimum password length has changed.

Restrictions and guidelines

You can use the **display password-control** command to display password control configuration. For more information about password control commands, see password control commands in *Security Command Reference*.

Procedure

1. Enter system view.
   system-view
2. Enable password change prompt logging.
   local-server log change-password-prompt
   By default, password change prompt logging is enabled.

Configuring the RADIUS server feature

RADIUS server feature tasks at a glance

To configure the RADIUS server feature, perform the following tasks:

1. Configuring RADIUS users
2. Specifying RADIUS clients
3. Activating the RADIUS server configuration

Restrictions and guidelines for the RADIUS server feature

To ensure correct operation of the RADIUS server feature, disable RADIUS session-control on the device.

Configuring RADIUS users

To configure RADIUS users, you must configure network access users, which are the basis of RADIUS user data.

A RADIUS user has the following attributes: user name, password, description, authorization ACL, authorization VLAN, and expiration time. For more information, see "Configuring attributes for network access users."

Specifying RADIUS clients

About this task

Perform this task to specify RADIUS clients and shared keys for centralized management. The RADIUS server feature does not accept requests from RADIUS clients that are not managed by the system.

Restrictions and guidelines

The IP address of a RADIUS client must be the same as the source IP address for outgoing RADIUS packets specified on the RADIUS client.

The shared key of a RADIUS client specified on the RADIUS server must be the same as the setting on the RADIUS client.

Procedure

1. Enter system view.
   `system-view`
2. Specify a RADIUS client.
   `radius-server client ip` *`ipv4-address`* **`key`** { **`cipher`** | **`simple`** } *`string`*

Activating the RADIUS server configuration

About this task

At the device startup, the RADIUS server configuration is automatically activated, including RADIUS users and RADIUS clients. You can immediately activate the most recent RADIUS server configuration if you have added, modified, or deleted RADIUS clients and network access users from which RADIUS user data is generated.

Procedure

1. Enter system view.
   `system-view`
2. Activate the RADIUS server configuration.
   `radius-server activate`

   Executing this command restarts the RADIUS server process and an authentication service interruption will occur during the restart.

Display and maintenance commands for RADIUS users and clients

Execute **`display`** commands in any view.

Task	Command
Display information about activated RADIUS users.	**`display radius-server active-user`** [*`user-name`*]
Display information about activated RADIUS clients.	**`display radius-server active-client`**

Configuring the connection recording policy

About the connection recording policy

Use this feature on scenarios where the device acts as an FTP, SSH, SFTP, or Telnet login client to establish a connection with a login server. This feature enables the device to provide an accounting server with the connection start and termination information. When the login client establishes a connection with the login server, the system sends a start-accounting request to the accounting server. When the connection is terminated, the system sends a stop-accounting request to the accounting server.

Restrictions and guidelines

The device includes the username entered by a user in the accounting packets to be sent to the AAA server for connection recording. The username format configured by using the **user-name-format** command in the accounting scheme does not take effect.

Procedure

1. Enter system view.
   system-view
2. Create a connection recording policy and enter its view.
   aaa connection-recording policy
3. Specify the accounting method for the connection recording policy.
   accounting hwtacacs-scheme *hwtacacs-scheme-name*

Display and maintenance commands for the connection recording policy

Execute **display** commands in any view.

Task	Command
Display the connection recording policy configuration.	**display aaa connection-recording policy**

Displaying user MAC and UUID binding entries

About this task

To help administrators identify whether a universally unique identifier (UUID) has been assigned to a user and maintain the MAC and UUID binding entries for users, use this feature.

In some scenarios, administrators configure and manage MAC address and UUID binding entries for users on the authentication server, depending on the user access control policies. The binding entries will be assigned to the users after they pass authentication. The device automatically generates the MAC and UUID binding entry of a user when the user comes online and automatically deletes the binding entry when the user goes offline.

When a user's client requests the DHCP server to assign or release an IP address, the DHCP snooping module first searches for the UUID bound to the client MAC address. Then, the device replaces the value of Option 61 (client ID) in the client's DHCP packets with the UUID and forwards the DHCP packets to the DHCP server. The DHCP server will assign or reclaim an IP address based on the UUID in the received DHCP packets. UUID-based IP address assignment flexibly meets the IP address requirements of different scenarios.

Restrictions and guidelines

The device supports user MAC and UUID binding entries only for 802.1X and MAC authentication users that use the iNode client.

Procedure

To display user MAC and UUID binding entries, execute the following command in any view:

display mubm record [**mac** *mac-address*] [**interface** *interface-type interface-number* | **slot** *slot-number*] [**access-type** { **dot1x** | **mac-auth** }]

Configuring user online and offline recording

About user online and offline recording

This feature enables the device to record user information when the users fail to come online, or the users go offline normally or abnormally. These records help the administrator to quickly identify the causes of user online and offline faults. The feature occupies the system memory. To reduce the memory usage, you can disable this feature.

Restrictions and guidelines for user online and offline recording configuration

This feature is applicable only to portal, login, and LAN users.

Enabling user online failure recording

1. Enter system view.
   system-view
2. Enable user online failure recording.
   aaa online-fail-record enable
   By default, user online failure recording is disabled.

Enabling user offline recording

1. Enter system view.
   system-view
2. Enable user offline recording.
   aaa offline-record enable
   By default, user offline recording is disabled.
3. Enable user normal offline recording.
   aaa normal-offline-record enable
   By default, user normal offline recording is disabled.

4. Enable user abnormal offline recording.

   aaa abnormal-offline-record enable

   By default, user abnormal offline recording is disabled.

Enabling real-time recording of AAA user associations and disassociations

1. Enter system view.

   system-view

2. Enabling real-time recording of AAA user associations and disassociations.

   aaa { **abnormal-offline-record** | **normal-offline-record** | **online-fail-record** } * **realtime-backup enable**

   By default, real-time recording of AAA user associations and disassociations is disabled.

Display and maintenance commands for user online and offline recording

Execute **display** commands in any view and **reset** commands in user view and **reset** commands in user view.

Task	Command
Display user abnormal offline records.	**display aaa abnormal-offline-record** { **access-type** { **lan-access** | **login** | **portal** } | **domain** *domain-name* | **interface** *interface-type interface-number* | { **ip** *ipv4-address* | **ipv6** *ipv6-address* } | **mac-address** *mac-address* | **s-vlan** *svlan-id* [**c-vlan** *cvlan-id*] | **slot** *slot-number* | **username** *user-name* [**fuzzy-match**] | **reason-code** *code* } * [**time** *begin-time end-time* [**date** *begin-date end-date*]] [**brief** | **count** *count*] **display aaa abnormal-offline-record offline-reason** { **idle-cut** | **quota-out** | **realtime-acct-fail** | **session-timeout** | **user-detect-fail** } [**brief**] **display aaa abnormal-offline-record time** *begin-time end-time* [**date** *begin-date end-date*] [**brief**] **display aaa abnormal-offline-record**
Display user normal offline records.	**display aaa normal-offline-record** { **access-type** { **lan-access** | **login** | **portal** } | **domain** *domain-name* | **interface** *interface-type interface-number* | { **ip** *ipv4-address* | **ipv6** *ipv6-address* } | **mac-address** *mac-address* | **s-vlan** *svlan-id* [**c-vlan** *cvlan-id*] | **slot** *slot-number* | **username** *user-name* [**fuzzy-match**] | **reason-code** *code* } * [**time** *begin-time end-time* [**date** *begin-date end-date*]] [**brief** | **count** *count*] **display aaa normal-offline-record time**

	begin-time end-time [**date** *begin-date end-date*] [**brief**] **display aaa normal-offline-record**
Display user offline records.	**display aaa offline-record** { **access-type** { **lan-access** | **login** | **portal** } | **domain** *domain-name* | **interface** *interface-type interface-number* | { **ip** *ipv4-address* | **ipv6** *ipv6-address* } | **mac-address** *mac-address* | **s-vlan** *svlan-id* [**c-vlan** *cvlan-id*] | **slot** *slot-number* | **username** *user-name* [**fuzzy-match**] | **reason-code** *code* } * [**time** *begin-time end-time* [**date** *begin-date end-date*]] [**brief** | **count** *count*] **display aaa offline-record time** *begin-time end-time* [**date** *begin-date end-date*] [**brief**] **display aaa offline-record**
Display user online failure records.	**display aaa online-fail-record** { **access-type** { **lan-access** | **login** | **portal** } | **domain** *domain-name* | **interface** *interface-type interface-number* | { **ip** *ipv4-address* | **ipv6** *ipv6-address* } | **mac-address** *mac-address* | **s-vlan** *svlan-id* [**c-vlan** *cvlan-id*] | **slot** *slot-number* | **username** *user-name* [**fuzzy-match**] | **reason-code** *code* } * [**time** *begin-time end-time* [**date** *begin-date end-date*]] [**brief** | **count** *count*] **display aaa online-fail-record time** *begin-time end-time* [**date** *begin-date end-date*] [**brief**] **display aaa online-fail-record**
Clear user abnormal offline records.	**reset aaa abnormal-offline-record**
Clear user normal offline records.	**reset aaa normal-offline-record**
Clear user offline records.	**reset aaa offline-record**
Clear user online failure records.	**reset aaa online-fail-record**

Configuring the AAA test feature

About this task

This feature enables the device to send authentication or accounting requests to the specified AAA servers to simulate an authentication or accounting process of a user. Use this feature to identify the reasons for the failure of the interaction between the device and the AAA servers. This feature is applicable only to RADIUS.

When performing an AAA test, the device ignores the status of the specified AAA servers and the RADIUS server load sharing feature. The process of an AAA test is as follows:

1. The device sends authentication requests that carry the specified username and password to the specified authentication server or to the authentication servers in the specified RADIUS scheme. The device tries to communicate with the authentication servers in the specified scheme in sequence.

The process goes to the next step in the following situations:

- The device receives an authentication response (no matter the authentication succeeds or fails).
- The device does not receive any authentication response after making all authentication request attempts.

This step is skipped if no correct authentication server is specified for the AAA test or no authentication servers are configured in the specified RADIUS scheme.

2. The device sends start-accounting requests to the specified accounting server or to the accounting servers in the specified RADIUS scheme. The device tries to communicate with the accounting servers in the specified scheme in sequence.

   The process goes to the next step in the following situations:

   - The device receives a start-accounting response (no matter the accounting succeeds or fails).
   - The device does not receive any start-accounting response after making all start-accounting request attempts.

   This step and the next step are skipped if no correct accounting server is specified for the AAA test or no accounting servers are configured in the specified RADIUS scheme.

3. The device sends stop-accounting requests to the accounting servers to which it has sent a start-accounting request.

   The process finishes in the following situations:

   - The device receives a stop-accounting response.
   - The device does not receive any stop-accounting response after making all stop-accounting request attempts.

To identify attributes that cause authentication or accounting failures, you can configure the device to carry specific attributes in RADIUS requests or define values for specific attributes in the requests. Table 4 shows the attributes that RADIUS requests carry by default.

Table 4 Attributes that RADIUS requests carry by default

Packet type	Attributes that the type of packets carry by default
RADIUS authentication request	User-Name CHAP-Password (or User-Password) CHAP-Challenge NAS-IP-Address (or NAS-IPv6-Address) Service-Type Framed-Protocol NAS-Identifier NAS-Port-Type Acct-Session-Id
RADIUS accounting request	User-Name Acct-Status-Type NAS-IP-Address (or NAS-IPv6-Address) NAS-Identifier Acct-Session-Id Acct-Delay-Time Acct-Terminate-Cause

Restrictions and guidelines

When you perform an AAA test, follow these restrictions and guidelines:

- The device might communicate with the AAA servers incorrectly during an AAA test. Make sure no users come online or go offline during an AAA text.
- If the configuration of the specified RADIUS scheme changes, the new configuration does not affect the current AAA test. The modification will take effect in the next test.
- The system can have only one AAA test at a time. Another AAA test can be performed only after the current test finishes.

When you configure attributes to be included in or excluded from RADIUS requests, follow these restrictions and guidelines:

- Before you include an attribute that is already configured to be excluded from RADIUS requests, you must cancel the exclusion configuration by using the **undo exclude** command.
- Before you exclude an attribute that is already configured to be included in RADIUS requests, you must cancel the inclusion configuration by using the **undo include** command.

Prerequisites

Before you perform an AAA test, you must configure a RADIUS scheme that contains the RADIUS servers to be tested.

Plan the RADIUS attributes to be included in RADIUS requests. Besides the attributes carried by default, the device adds the specified attributes to RADIUS packets in the order that they are specified by using the **include** command. Additional attributes cannot be added to a RADIUS request if the length of the RADIUS request reaches 4096 bytes.

Procedure

1. (Optional.) Configure a RADIUS attribute test group:
   a. Enter system view.
      system-view
   b. Create a RADIUS attribute test group and enter its view.
      radius attribute-test-group *attr-test-group-name*
      You can create multiple RADIUS attribute test groups.
   c. Include an attribute in RADIUS requests.
      include { **accounting** | **authentication** } { **name** *attribute-name* | [**vendor** *vendor-id*] **code** *attribute-code* } **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** } value *attribute-value*
      Use this command to add attributes that RADIUS requests do not carry by default to the RADIUS requests.
      For an attribute that RADIUS requests carry by default, you can use this command to change its attribute value.
   d. Exclude an attribute from RADIUS requests.
      exclude { **accounting** | **authentication** } **name** *attribute-name*
      Use this command to exclude an attribute that RADIUS requests carry by default from the RADIUS requests sent during an AAA test to help troubleshoot authentication or accounting failures.
   e. Return to system view.
      quit
   f. Return to user view.
      quit
2. Perform an AAA test in user view.
   test-aaa user *user-name* **password** *password* **radius-scheme** *radius-scheme-name* [**radius-server** { *ipv4-address* | **ipv6**

ipv6-address } *port-number* [**vpn-instance** *vpn-instance-name*]] [**chap** | **pap**] [**attribute-test-group** attr-*test-group-name*] [**trace**]

Configuring authorization information cache for AAA users

Enabling RADIUS authorization information cache for LAN users

About this task

With this feature enabled, when a LAN user passes RADIUS authentication and comes online in an ISP domain, the system records the authorization information returned by the RADIUS server in the authorization information cache. When the user tries to perform RADIUS authentication and come online in the same ISP domain again, if no server is available, the system queries the cached authorization information for the user. If a match is found, the system uses the cached information to perform authentication and authorization and returns authentication success to the user.

With this feature disabled, the system does not record the authorization information returned by the RADIS server for users.

Restrictions and guidelines

For this feature to take effect, you must also enable authorization information cache for AAA users globally (**aaa authorization-cache enable**).

To use this feature, if the accounting scheme and authentication scheme are the same in the ISP domain, configure RADIUS-based remote authentication as the primary accounting method and configure no authentication as the backup accounting method, or allow users that have failed all their accounting-update attempts to stay online.

Procedure

1. Enter system view.
   system-view
2. Enable authorization information cache for AAA users.
   aaa authorization-cache enable
   By default, authorization information cache is disabled for AAA users.
3. Specify the aging time of authorization information cache entries.
   aaa authorization-cache expiry *expiry-time*
   By default, the aging time of authorization information cache entries is 336 hours.
4. Enter ISP domain view.
   domain *isp-name*
5. Enable RADIUS authorization information cache for LAN users.
   authorization lan-access radius-cache enable
   By default, RADIUS authorization information cache is disabled for LAN users.

Display and maintenance commands for authorization information cache for AAA users

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the recorded authorization information cache entries.	**display aaa authorization-cache** [**dot1x** | **mac-auth** | **static** | **web-auth**] [**mac** *mac-address*]
Clear the recorded authorization information cache entries.	**reset aaa authorization-cache** [**dot1x** | **mac-auth** | **static** | **web-auth**] [mac *mac-address*] [**username** *username*]

Enable authorization information cache for AAA users globally

About this task

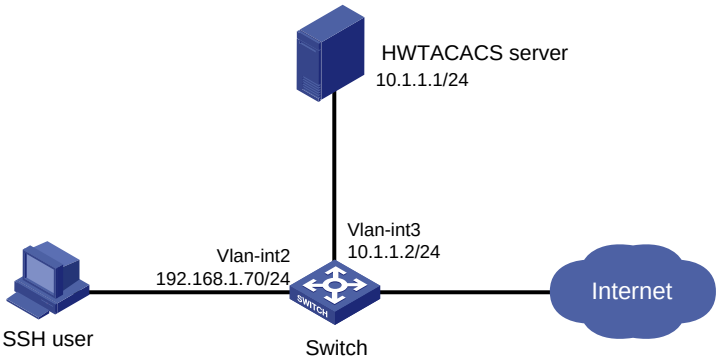
This feature enables the system to record and query specific authorization information cache of users during the authentication process in each ISP domain. After you disable this feature, the system stops recording and querying user authorization information cache and deletes existing authorization information cache entries.

Procedure

1. Enter system view.
   system-view
2. Enable authorization information cache for AAA users.
   aaa authorization-cache enable
   By default, authorization information cache is disabled for AAA users.
3. Specify the aging time of authorization information cache entries.
   aaa authorization-cache expiry *expiry-time*
   By default, the aging time of authorization information cache entries is 336 hours.
4. Specify the maximum number of authorization information cache entries for AAA users.
   aaa authorization-cache max-number max-number
   By default, the system can record a maximum of 8000 authorization information cache entries for AAA users.
5. Specify the aging time of authorization information cache entries for AAA users matching the specified ACL.
   aaa authorization-cache acl *acl-number* **expiry** *expiry-time*
   By default, the aging time is determined by the configuration of the **aaa authorization-cache expiry** command.

AAA configuration examples

Example: Configuring AAA for SSH users by an HWTACACS server



Network configuration

As shown in Figure 16, configure the switch to meet the following requirements:

- Use the HWTACACS server for SSH user authentication, authorization, and accounting.

- Assign the default user role **network-operator** to SSH users after they pass authentication.
- Exclude domain names from the usernames sent to the HWTACACS server.
- Use **expert** as the shared keys for secure HWTACACS communication.

Figure 16 Network diagram

Configuring the HWTACACS server

Set the shared keys to **expert** for secure communication with the switch, add an account for the SSH user, and specify the password. (Details not shown.)

Configuring the switch

Configure IP addresses for the interfaces. (Details not shown.)

Create an HWTACACS scheme.

```
<Switch> system-view
[Switch] hwtacacs scheme hwtac
```

Specify the primary authentication server.

```
[Switch-hwtacacs-hwtac] primary authentication 10.1.1.1 49
```

Specify the primary authorization server.

```
[Switch-hwtacacs-hwtac] primary authorization 10.1.1.1 49
```

Specify the primary accounting server.

```
[Switch-hwtacacs-hwtac] primary accounting 10.1.1.1 49
```

Set the shared keys to **expert** in plaintext form for secure HWTACACS communication.

```
[Switch-hwtacacs-hwtac] key authentication simple expert
[Switch-hwtacacs-hwtac] key authorization simple expert
[Switch-hwtacacs-hwtac] key accounting simple expert
```

Exclude domain names from the usernames sent to the HWTACACS server.

```
[Switch-hwtacacs-hwtac] user-name-format without-domain
[Switch-hwtacacs-hwtac] quit
```

Create an ISP domain named **bbb** and configure the domain to use the HWTACACS scheme for authentication, authorization, and accounting of login users.

```
[Switch-isp-bbb] authentication login hwtacacs-scheme hwtac
[Switch-isp-bbb] authorization login hwtacacs-scheme hwtac
[Switch-isp-bbb] accounting login hwtacacs-scheme hwtac
[Switch-isp-bbb] quit
```

Create local RSA and DSA key pairs.

```
[Switch] public-key local create rsa
[Switch] public-key local create dsa
```

Enable the Stelnet service.

```
[Switch] ssh server enable
```

Enable scheme authentication for user lines VTY 0 through VTY 63.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Enable the default user role feature to assign authenticated SSH users the default user role **network-operator**.

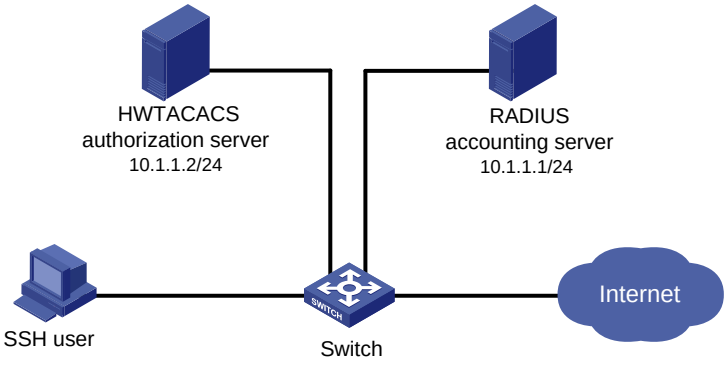
```
[Switch] role default-role enable
```

Verifying the configuration

Initiate an SSH connection to the switch, and enter the correct username and password. The user logs in to the switch. The username must carry the domain name **bbb** in the *username*@**bbb** format. (Details not shown.)

Verify that the user can use the commands permitted by the network-operator user role. (Details not shown.)

Example: Configuring local authentication, HWTACACS authorization, and RADIUS accounting for SSH users



Network configuration

As shown in Figure 17, configure the switch to meet the following requirements:

- Perform local authentication for SSH users.
- Use the HWTACACS server and RADIUS server for SSH user authorization and accounting, respectively.
- Exclude domain names from the usernames sent to the servers.
- Assign the default user role **network-operator** to SSH users after they pass authentication.

Configure an account named **hello** for the SSH user. Configure the shared keys to **expert** for secure communication with the HWTACACS server and RADIUS server.

Figure 17 Network diagram

Configuring the HWTACACS server

Set the shared keys to **expert** for secure communication with the switch, add an account for the SSH user, and specify the password. (Details not shown.)

Configuring the RADIUS server

Set the shared keys to **expert** for secure communication with the switch, add an account for the SSH user, and specify the password. (Details not shown.)

Configuring the switch

Configure IP addresses for interfaces. (Details not shown.)

Create local RSA and DSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
[Switch] public-key local create dsa
```

Enable the Stelnet service.

```
[Switch] ssh server enable
```

Enable scheme authentication for user lines VTY 0 through VTY 63.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Configure an HWTACACS scheme.

```
[Switch] hwtacacs scheme hwtac
[Switch-hwtacacs-hwtac] primary authorization 10.1.1.2 49
[Switch-hwtacacs-hwtac] key authorization simple expert
[Switch-hwtacacs-hwtac] user-name-format without-domain
[Switch-hwtacacs-hwtac] quit
```

Configure a RADIUS scheme.

```
[Switch] radius scheme rd
[Switch-radius-rd] primary accounting 10.1.1.1 1813
[Switch-radius-rd] key accounting simple expert
[Switch-radius-rd] user-name-format without-domain
[Switch-radius-rd] quit
```

Create a device management user.

```
[Switch] local-user hello class manage
```

Assign the SSH service to the local user.

```
[Switch-luser-manage-hello] service-type ssh
```

Set the password to **123456TESTplat&!** in plaintext form for the local user. In FIPS mode, you must set the password in interactive mode.

```
[Switch-luser-manage-hello] password simple 123456TESTplat&!
[Switch-luser-manage-hello] quit
```

Create an ISP domain named **bbb** and configure the login users to use local authentication, HWTACACS authorization, and RADIUS accounting.

```
[Switch] domain bbb
[Switch-isp-bbb] authentication login local
[Switch-isp-bbb] authorization login hwtacacs-scheme hwtac
[Switch-isp-bbb] accounting login radius-scheme rd
[Switch-isp-bbb] quit
```

Enable the default user role feature to assign authenticated SSH users the default user role **network-operator**.

```
[Switch] role default-role enable
```

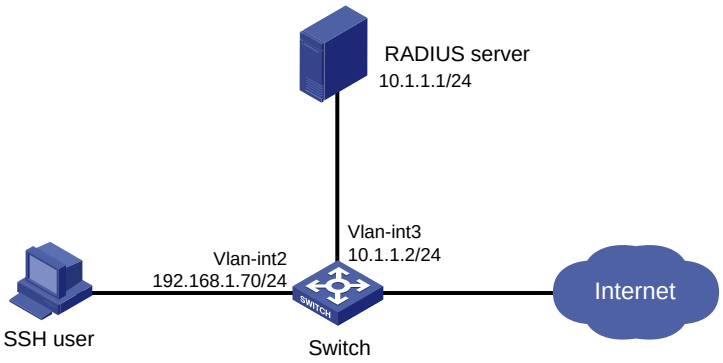
Verifying the configuration

Initiate an SSH connection to the switch, and enter username **hello@bbb** and the correct password. The user logs in to the switch. (Details not shown.)

Verify that the user can use the commands permitted by the network-operator user role. (Details not shown.)

Example: Configuring authentication and authorization for SSH users by a RADIUS server

Network configuration



As shown in Figure 18, configure the switch to meet the following requirements:

- Use the RADIUS server for SSH user authentication and authorization.
- Include domain names in the usernames sent to the RADIUS server.
- Assign the **network-admin** user role to SSH users after they pass authentication.

The RADIUS server runs IMC PLAT 7.3 (E0605) and IMC UAM 7.3 (E0512). Add an account with username **hello@bbb** on the RADIUS server.

The RADIUS server and the switch use **expert** as the shared key for secure RADIUS communication. The ports for authentication and accounting are **1812** and **1813**, respectively.

Figure 18 Network diagram

Configuring the RADIUS server

1. Add the switch to the IMC Platform as an access device:

   Log in to IMC, click the **User** tab, and select **User Access Policy** > **Access Device Management** > **Access Device** from the navigation tree. Then, click **Add** to configure an access device as follows:

   a. Set the ports for authentication and accounting to 1812 and 1813, respectively.

   b. Select **Device Management Service** from the **Service Type** list.

   c. Select **H3C (General)** from the **Access Device Type** list.

   d. Set the shared key to **expert** for secure RADIUS communication.

   e. Select an access device from the device list or manually add an access device. In this example, the device IP address is 10.1.1.2.

   f. Use the default values for other parameters and click **OK**.

   The IP address of the access device specified here must be the same as the source IP address of the RADIUS packets sent from the switch. The source IP address is chosen in the following order on the switch:

   - IP address specified by using the **`nas-ip`** command.

- IP address specified by using the **`radius nas-ip`** command.
- IP address of the outbound interface (the default).

Figure 19 Adding the switch as an access device

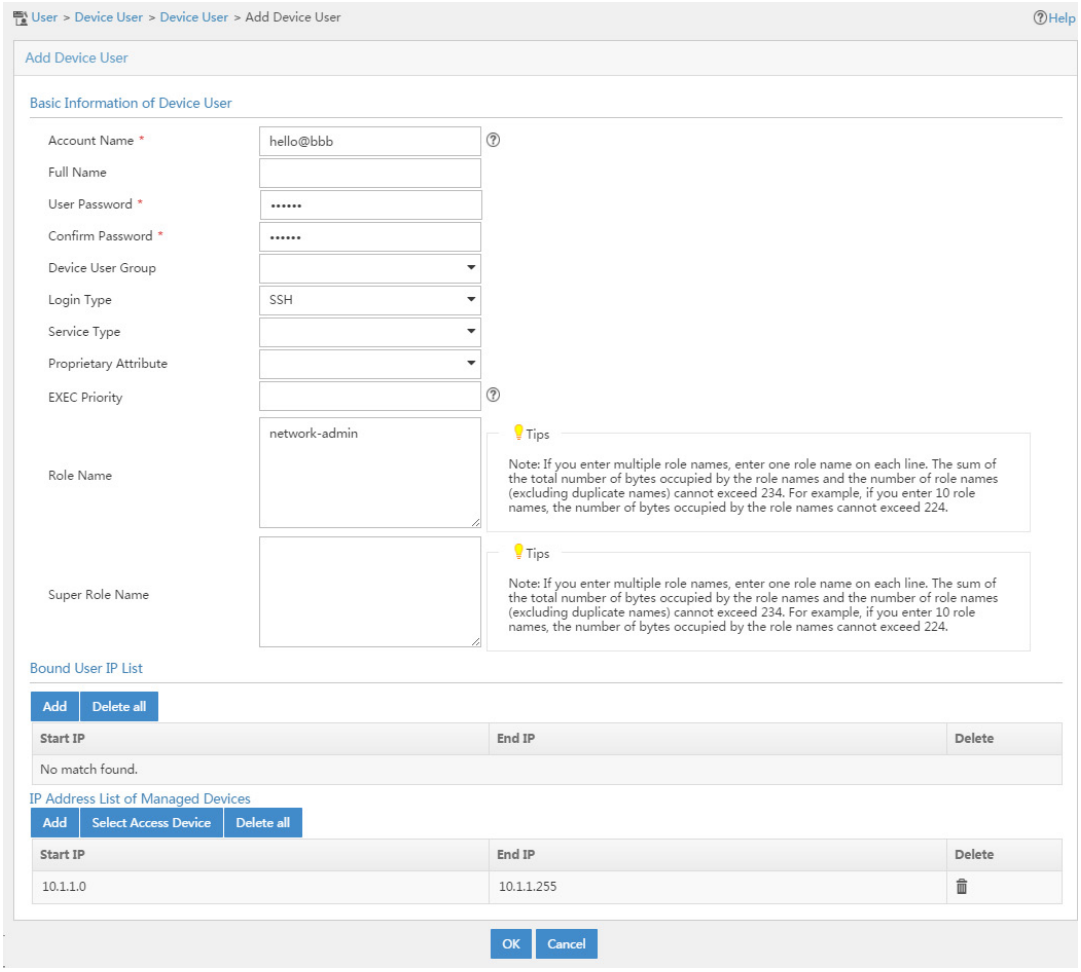
2. Add an account for device management:

Click the **User** tab, and select **Device User** > **Device User** from the navigation tree. Then, click **Add** to configure a device management account as follows:

a. Enter account name **hello@bbb** and specify the password.

b. Select **SSH** from the **Login Type** list.

c. Enter user role **network-admin**.



d. Specify 10.1.1.0 to 10.1.1.255 as the IP address range of the hosts to be managed.

e. Click **OK**.

NOTE:

The IP address range must contain the IP address of the switch.

Figure 20 Adding an account for device management

Configuring the switch

Configure IP addresses for interfaces. (Details not shown.)

Create local RSA and DSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
[Switch] public-key local create dsa
```

Enable the Stelnet service.

```
[Switch] ssh server enable
```

Enable scheme authentication for user lines VTY 0 through VTY 63.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Create a RADIUS scheme.

```
[Switch] radius scheme rad
```

Specify the primary authentication server.

```
[Switch-radius-rad] primary authentication 10.1.1.1 1812
```

Set the shared key to **expert** in plaintext form for secure communication with the server.

```
[Switch-radius-rad] key authentication simple expert
```

Include domain names in the usernames sent to the RADIUS server.

```
[Switch-radius-rad] user-name-format with-domain
[Switch-radius-rad] quit
```

Create an ISP domain named **bbb** and configure authentication, authorization, and accounting methods for login users.

```
[Switch] domain bbb
[Switch-isp-bbb] authentication login radius-scheme rad
[Switch-isp-bbb] authorization login radius-scheme rad
[Switch-isp-bbb] accounting login none
[Switch-isp-bbb] quit
```

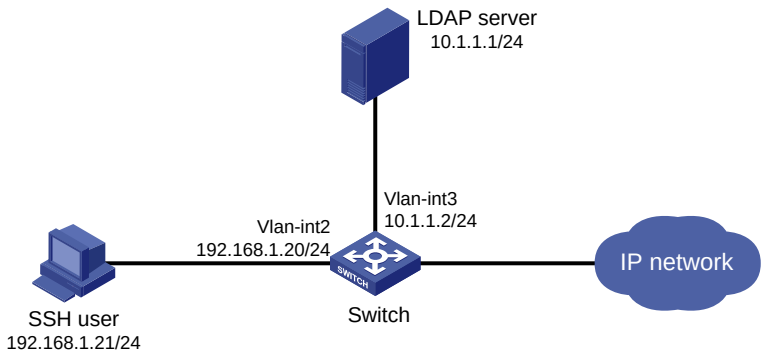
Verifying the configuration

Initiate an SSH connection to the switch, and enter username **hello@bbb** and the correct password. The user logs in to the switch. (Details not shown.)

Verify that the user can use the commands permitted by the network-admin user role. (Details not shown.)

Example: Configuring authentication for SSH users by an LDAP server

Network configuration



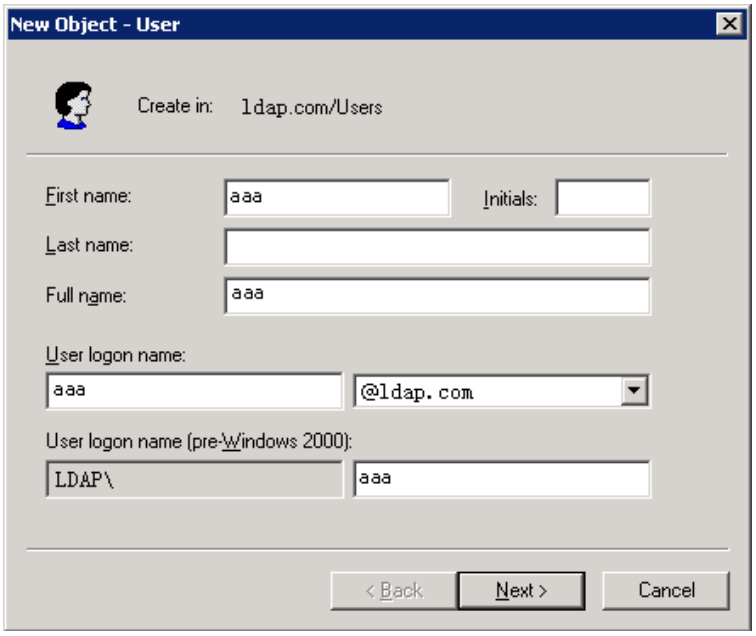
As shown in Figure 21, the LDAP server uses domain **ldap.com** and runs Microsoft Windows 2003 Server Active Directory.

Configure the switch to meet the following requirements:

- Use the LDAP server to authenticate SSH users.
- Assign the level-0 user role to SSH users after they pass authentication.

On the LDAP server, set the administrator password to **admin!123456**, add a user named **aaa**, and set the user's password to **ldap!123456**.

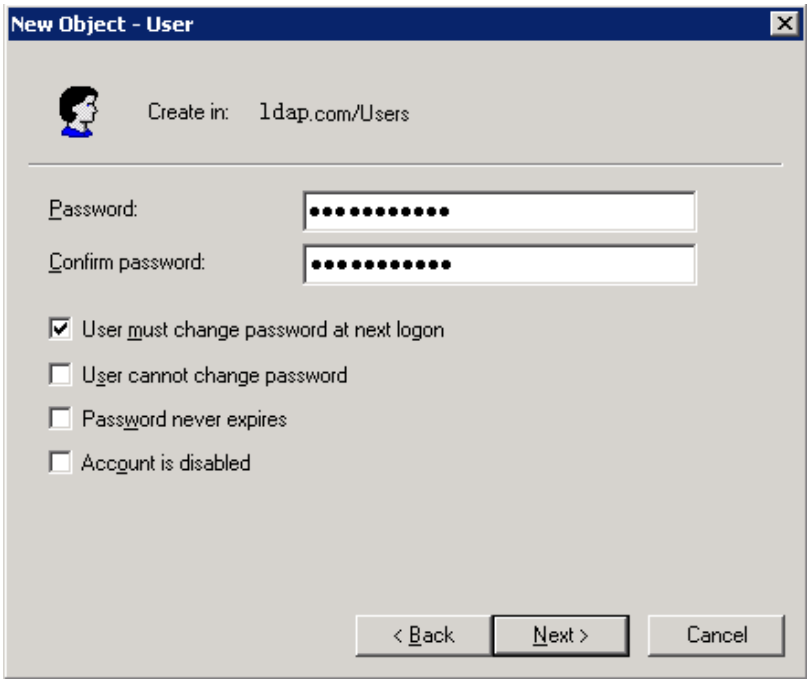
Figure 21 Network diagram



Configuring the LDAP server

1. Add a user named **aaa** and set the password to **ldap!123456**:
   a. On the LDAP server, select **Start** > **Control Panel** > **Administrative Tools**.
   b. Double-click **Active Directory Users and Computers**.
      The **Active Directory Users and Computers** window is displayed.
   c. From the navigation tree, click **Users** under the **ldap.com** node.

d. Select **Action** > **New** > **User** from the menu to display the dialog box for adding a user.



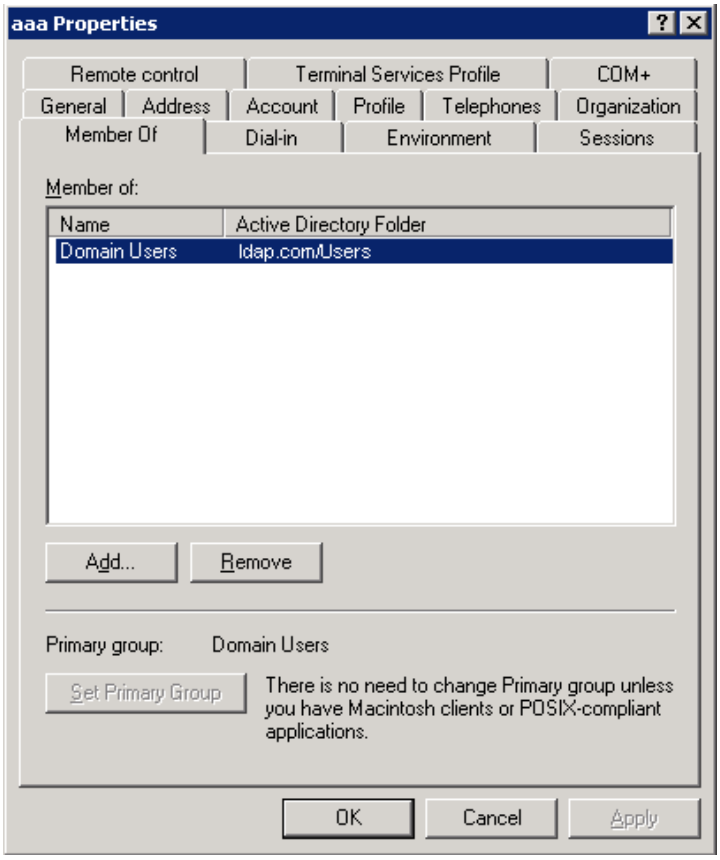
e. Enter logon name **aaa** and click **Next**.

Figure 22 Adding user aaa

f. In the dialog box, enter password **ldap!123456**, select options as needed, and click **Next**.

Figure 23 Setting the user's password

g. Click **OK**.



2. Add user **aaa** to group **Users**:

a. From the navigation tree, click **Users** under the **ldap.com** node.

b. In the right pane, right-click user **aaa** and select **Properties**.

c. In the dialog box, click the **Member Of** tab and click **Add**.

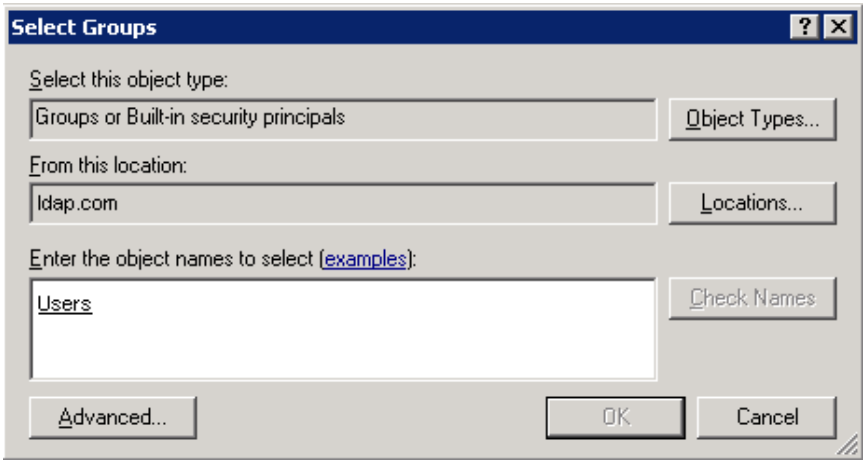


Figure 24 Modifying user properties

d. In the **Select Groups** dialog box, enter **Users** in the **Enter the object names to select** field, and click **OK**.

User **aaa** is added to group **Users**.

Figure 25 Adding user aaa to group Users

3. Set the administrator password to **admin!123456**:

a. In the right pane, right-click user **Administrator** and select **Set Password**.

b. In the dialog box, enter the administrator password. (Details not shown.)

Configuring the switch

Configure IP addresses for interfaces. (Details not shown.)

Create local RSA and DSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
[Switch] public-key local create dsa
```

Enable the Stelnet service.

```
[Switch] ssh server enable
```

Enable scheme authentication for user lines VTY 0 through VTY 63.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Configure an LDAP server.

```
[Switch] ldap server ldap1
```

Specify the IP address of the LDAP authentication server.

```
[Switch-ldap-server-ldap1] ip 10.1.1.1
```

Specify the administrator DN.

```
[Switch-ldap-server-ldap1] login-dn cn=administrator,cn=users,dc=ldap,dc=com
```

Specify the administrator password.

```
[Switch-ldap-server-ldap1] login-password simple admin!123456
```

Configure the base DN for user search.

```
[Switch-ldap-server-ldap1] search-base-dn dc=ldap,dc=com
[Switch-ldap-server-ldap1] quit
```

Create an LDAP scheme.

```
[Switch] ldap scheme ldap-shm1
```

Specify the LDAP authentication server.

```
[Switch-ldap-ldap-shm1] authentication-server ldap1
[Switch-ldap-ldap-shm1] quit
```

Create an ISP domain named **bbb** and configure authentication, authorization, and accounting methods for login users.

```
[Switch] domain bbb
[Switch-isp-bbb] authentication login ldap-scheme ldap-shm1
[Switch-isp-bbb] authorization login none
[Switch-isp-bbb] accounting login none
[Switch-isp-bbb] quit
```

Verifying the configuration

Initiate an SSH connection to the switch, and enter username **aaa@bbb** and password **ldap!123456**. The user logs in to the switch. (Details not shown.)

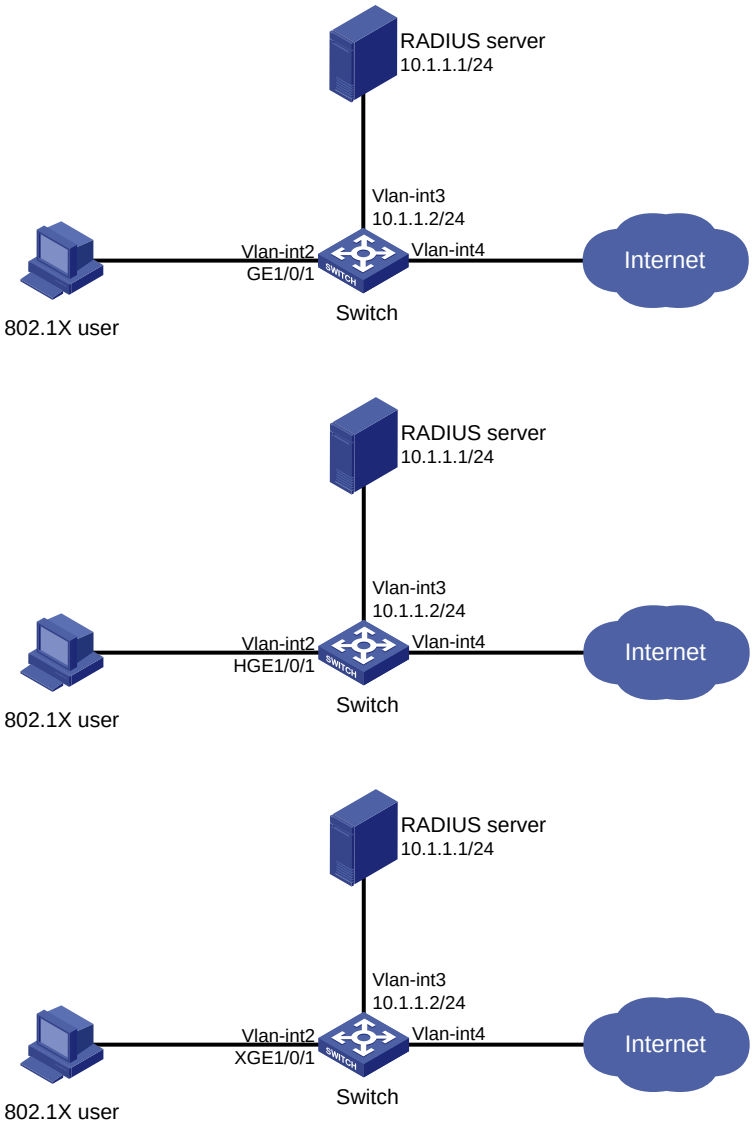
Verify that the user can use the commands permitted by the level-0 user role. (Details not shown.)

Example: Configuring AAA for 802.1X users by a RADIUS server

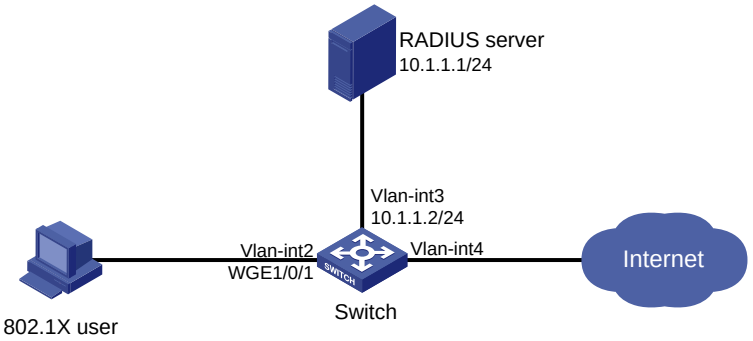
Network configuration

As shown in Figure 26, configure the switch to meet the following requirements:

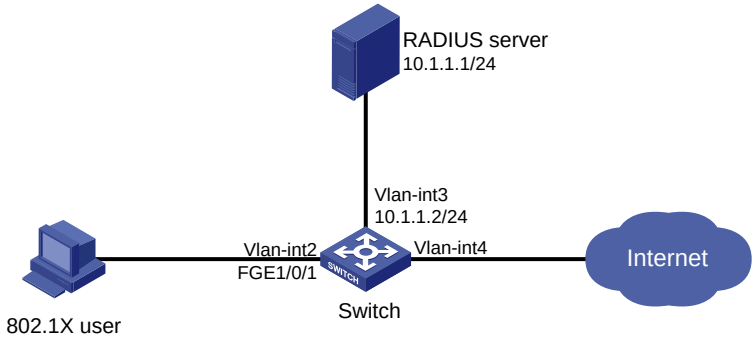
- Use the RADIUS server for authentication, authorization, and accounting of 802.1X users.



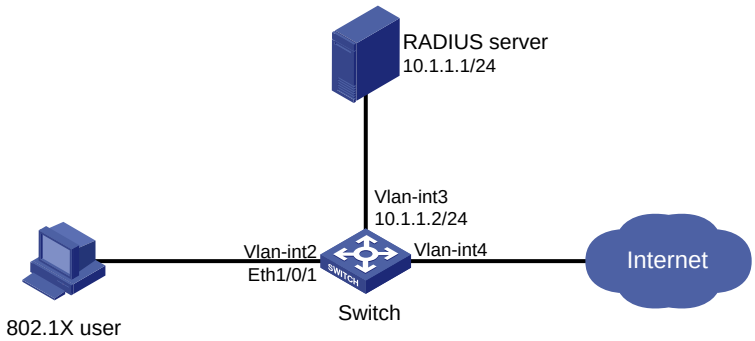
- Use MAC-based access control on GigabitEthernet 1/0/1 to authenticate all 802.1X users on the port separately.
- Include domain names in the usernames sent to the RADIUS server.



In this example, the RADIUS server runs IMC PLAT 7.1 (E0303), IMC UAM 7.1 (E0304), and IMC CAMS 7.1 (E0301). On the RADIUS server, perform the following tasks:



- Add a service that charges 120 dollars for up to 120 hours per month and assigns authenticated users to VLAN 4.
- Configure a user with name **dot1x@bbb** and assign the service to the user.



Set the shared keys to **expert** for secure RADIUS communication. Set the ports for authentication and accounting to 1812 and 1813, respectively.

Configuring the RADIUS server

1. Add the switch to the IMC Platform as an access device:

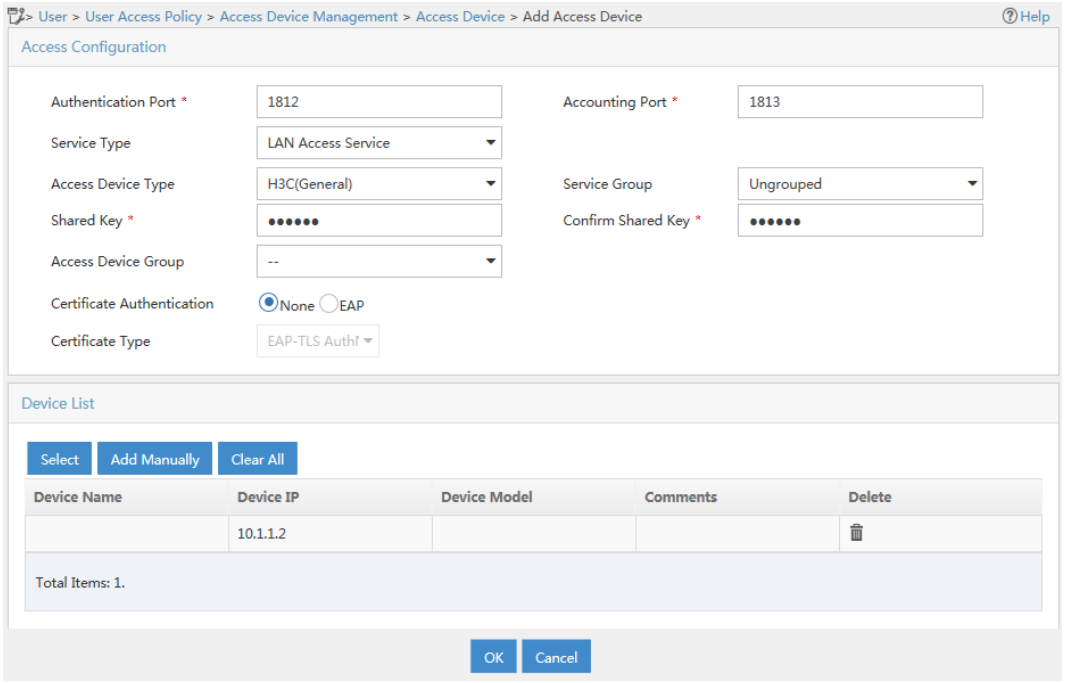
   Log in to IMC, click the **User** tab, and select **User Access Policy** > **Access Device Management** > **Access Device** from the navigation tree. Then, click **Add** to configure an access device as follows:

   a. Set the ports for authentication and accounting to 1812 and 1813, respectively.

b. Select **LAN Access Service** from the **Service Type** list.

c. Select **H3C(General)** from the **Access Device Type** list.

d. Set the shared key to **expert** for secure authentication and accounting communication.



e. Select an access device from the device list or manually add an access device. In this example, the device IP address is 10.1.1.2.

f. Use the default values for other parameters and click **OK**.

The IP address of the access device specified here must be the same as the source IP address of the RADIUS packets sent from the switch. The source IP address is chosen in the following order on the switch:

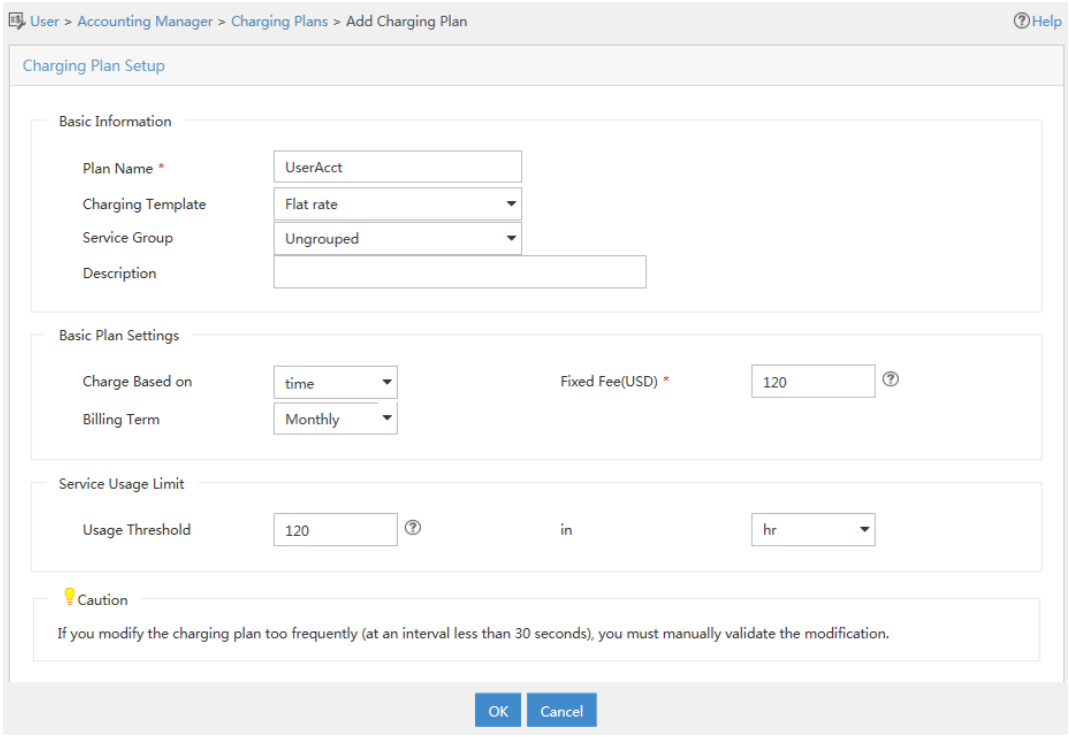
- IP address specified by using the **`nas-ip`** command.
- IP address specified by using the **`radius nas-ip`** command.
- IP address of the outbound interface (the default).

Figure 27 Adding the switch as an access device

2. Add a charging plan:

Click the **User** tab, and select **Accounting Manager** > **Charging Plans** from the navigation tree to enter the charging plan configuration page. Then, click **Add** to configure a charging plan as follows:

a. Add a plan named **UserAcct**.



b. Select **Flat rate** from the **Charging Template** list.

c. Select **time** for **Charge Based on**, select **Monthly** for **Billing Term**, and enter **120** in the **Fixed Fee** field.

d. Enter **120** in the **Usage Threshold** field and select **hr** (hours) for the **in** field. The configuration allows the user to access the Internet for up to 120 hours per month.

e. Click **OK**.

Figure 28 Adding a charging plan

3. Add an access policy:

   Click the **User** tab, and select **User Access Policy** > **Access Policy** from the navigation tree. Then, click **Add** to configure an access policy as follows:

   a. Enter access policy name **Dot1x auth**.

   b. Set the ID of the VLAN to be deployed to **4**.

   c. Configure other parameters as needed.

   d. Click **OK**.

Figure 29 Adding an access policy

4. Add an access service:

   Click the **User** tab, and select **User Access Policy** > **Access Service** from the navigation tree. Then, click **Add** to configure a service as follows:

   a. Add a service named **Dot1x Service,** and set the service suffix to **bbb**, the authentication domain for the 802.1X user. With the service suffix configured, you must configure the access device to send usernames that include domain names to the RADIUS server.

   b. Select **UserAcct** from the **Charging Plan** list.

   c. Select **Dot1x auth** from the **Default Access Policy** list.

   d. Configure other parameters as needed.

   e. Click **OK**.

Figure 30 Adding an access service

5. Add a user:

   Click the **User** tab, and select **All Access Users** from the navigation tree to enter the **All Access Users** page. Then, click **Add** to configure a user as follows:

   a. Select the user or add a user named **test**.

   b. Specify the account name as **dot1x** and configure the password.

   c. Select **Dot1x Service** in the **Access Service** area.

   d. Configure other parameters as needed and click **OK**.

Figure 31 Adding an access user account

Configuring the switch

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rad** and enter RADIUS scheme view.

   ```
   <Switch> system-view
   ```

```
[Switch] radius scheme rad
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rad] primary authentication 10.1.1.1
[Switch-radius-rad] primary accounting 10.1.1.1
[Switch-radius-rad] key authentication simple expert
[Switch-radius-rad] key accounting simple expert
```

Include domain names in the usernames sent to the RADIUS server.

```
[Switch-radius-rad] user-name-format with-domain
[Switch-radius-rad] quit
```

2. Configure an ISP domain:

   # Create an ISP domain named **bbb** and enter ISP domain view.

   ```
   [Switch] domain bbb
   ```

   # Configure the ISP domain to use RADIUS scheme **rad** for authentication, authorization, and accounting of LAN users.

   ```
   [Switch-isp-bbb] authentication lan-access radius-scheme rad
   [Switch-isp-bbb] authorization lan-access radius-scheme rad
   [Switch-isp-bbb] accounting lan-access radius-scheme rad
   [Switch-isp-bbb] quit
   ```

3. Configure 802.1X authentication:

   # Enable 802.1X globally.

   ```
   [Switch] dot1x
   ```

   # Enable 802.1X for GigabitEthernet 1/0/1.

   ```
   [Switch] interface gigabitethernet 1/0/1
   [Switch-GigabitEthernet1/0/1] dot1x
   ```

   # Configure the access control method. By default, an 802.1X-enabled port uses the MAC-based access control.

   ```
   [Switch-GigabitEthernet1/0/1] dot1x port-method macbased
   ```

Verifying the configuration

1. On the host, use account **dot1x@bbb** to pass 802.1X authentication:

   # If the host runs the Windows XP 802.1X client, configure the network connection properties as follows:

   a. Click the **Authentication** tab of the properties window.
   b. Select the **Enable IEEE 802.1X authentication for this network** option.
   c. Select MD5 challenge as the EAP type.
   d. Click **OK**.

   The user passes authentication after entering the correct username and password on the authentication page.

   # If the host runs the iNode client, no advanced authentication options are required. The user can pass authentication after entering username **dot1x@bbb** and the correct password on the client property page.

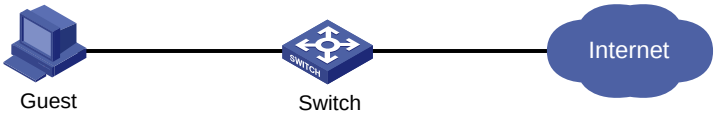
   IMPORTANT:

   Make sure the client can update its IP address to access the resources in the authorized VLAN after passing authentication.

2. On the switch, verify that the server assigns the port connecting the client to VLAN 4 after the user passes authentication. (Details not shown.)

3. Display 802.1X connection information on the switch.

```
[Switch] display dot1x connection
```



Example: Configuring and managing a local guest

Network configuration

As shown in Figure 32, create an 802.1X local guest named **user1** for Jack. Configure local guest attributes and manage the local guest on the switch as follows:

- Configure attributes for the local guest, including the password, user group, validity period, and sponsor information.
- Enable the local user auto-delete feature.
- Specify an SMTP server and email sender address for the device to send local guest email notifications.
- Configure email addresses for the local guest, guest manager, and guest sponsor.
- Configure the subject and body of the email notifications to be sent to the guest, guest sponsor, and guest manager.
- Send email notifications of the local guest account information to the guest and guest sponsor.

Figure 32 Network diagram

Procedure

1. Configure 802.1X settings. Make sure the guest can pass 802.1X authentication to access the network. (Details not shown.)
2. Manage local guests:

   # Enable the local user auto-delete feature for expired local guests.

   ```
   <Switch> system-view
   [Switch] local-user auto-delete enable
   ```

   # Specify an SMTP server to send local guest email notifications.

   ```
   [Switch] local-guest email smtp-server smtp://192.168.0.112/smtp
   ```

   # Specify the email sender address as **bbb@ccc.com** in the email notifications sent by the device for local guests.

   ```
   [Switch] local-guest email sender bbb@ccc.com
   ```

   # Specify the email address of the guest manager as **guest-manager@ccc.com**.

   ```
   [Switch] local-guest manager-email guest-manager@ccc.com
   ```

   # Configure the subject and body of the email notifications to be sent to the local guest.

   ```
   [Switch] local-guest email format to guest subject Guest account information
   [Switch] local-guest email format to guest body A guest account has been created for
   you. The username, password, and validity period of the account are given below.
   ```

   # Configure the subject and body of the email notifications to be sent to the guest sponsor.

   ```
   [Switch] local-guest email format to sponsor subject Guest account information
   [Switch] local-guest email format to sponsor body A guest account has been created
   for you. The username, password, and validity period of the account are given below.
   ```

   # Configure the subject and body of the email notifications to be sent to the guest manager.

   ```
   [Switch] local-guest email format to manager subject Guest registration information
   ```

```
[Switch] local-guest email format to manager body A guest account has been registered.
The username of the account is given below. Please approve the registration
information.
```

3. Configure the local guest:

Create a user group named **guest1**.

```
[Switch] user-group guest1
[Switch-ugroup-guest1] quit
```

Create a local guest named **user1** and enter local guest view.

```
[Switch] local-user user1 class network guest
```

Set the guest password to **123456** in plain text.

```
[Switch-luser-network(guest)-user1] password simple 123456
```

Assign the guest to user group **guest1**.

```
[Switch-luser-network(guest)-user1] group guest1
```

Specify the name of the local guest.

```
[Switch-luser-network(guest)-user1] full-name Jack
```

Specify the company of the local guest.

```
[Switch-luser-network(guest)-user1] company cc
```

Configure the email address of the local guest.

```
[Switch-luser-network(guest)-user1] email Jack@cc.com
```

Configure the phone number of the local guest.

```
[Switch-luser-network(guest)-user1] phone 131129237
```

Configure a description for the local guest.

```
[Switch-luser-network(guest)-user1] description A guest from company cc
```

Configure the validity period of the local guest.

```
[Switch-luser-network(guest)-user1] validity-datetime from 2015/4/1 08:00:00 to
2015/4/3 18:00:00
```

Specify the guest sponsor name as **Sam**.

```
[Switch-luser-network(guest)-user1] sponsor-full-name Sam
```

Configure the email address of the guest sponsor.

```
[Switch-luser-network(guest)-user1] sponsor-email Sam@aa.com
```

Configure the department of the guest sponsor as **security**.

```
[Switch-luser-network(guest)-user1] sponsor-department security
[Switch-luser-network(guest)-user1] quit
[Switch] quit
```

4. Configure the device to send guest email notifications:

Send an email notification to the guest sponsor.

```
<Switch> local-guest send-email user-name user1 to sponsor
```

Send an email notification to the guest.

```
<Switch> local-guest send-email user-name user1 to guest
```

Verifying the configuration

Display local guest information.

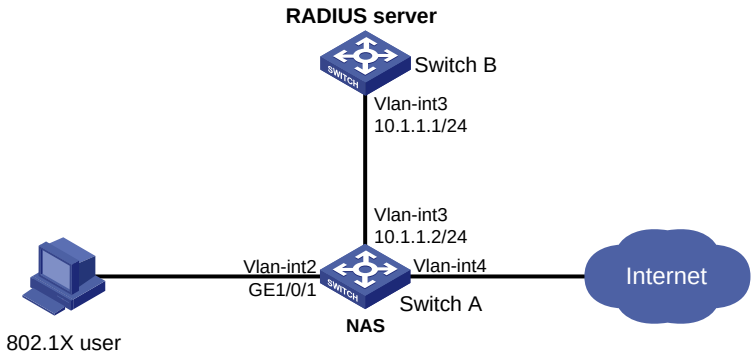
```
<Switch> display local-user user-name user1 class network guest
Total 1 local users matched.

Network access guest user1:
  State:                    Active
```

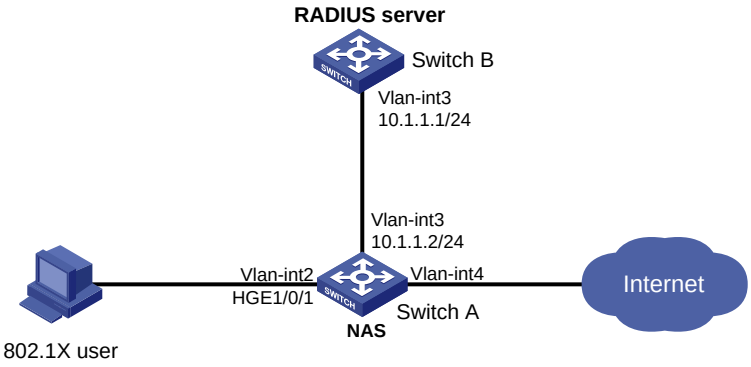
```
Service type:              LAN-access/Portal
User group:                guest1
Full name:                 Jack
Company:                   cc
Email:                     Jack@cc.com
Phone:                     131129237
Description:               A guest from company cc
Sponsor full name:         Sam
Sponsor department:        security
Sponsor email:             Sam@aa.com
Description:               A guest from company cc
Validity period:
  Start date and time:     2015/04/01-08:00:00
  Expiration date and time:2015/04/03-18:00:00
```

Verify that Jack can use username **user1** and password **123456** to pass local authentication and come online during the validity period. (Details not shown.)

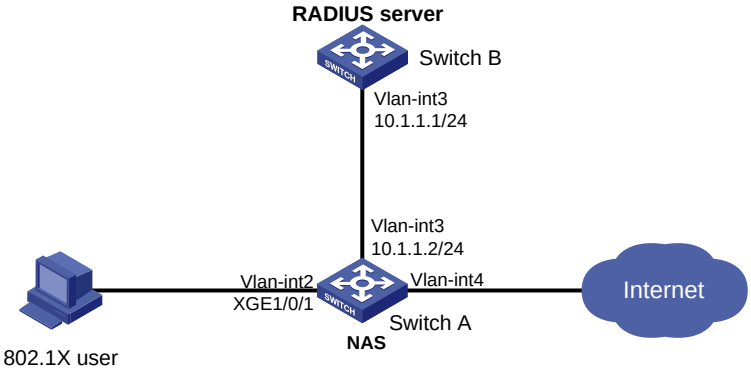
Example: Configuring authentication and authorization for 802.1X users by the device as a RADIUS server



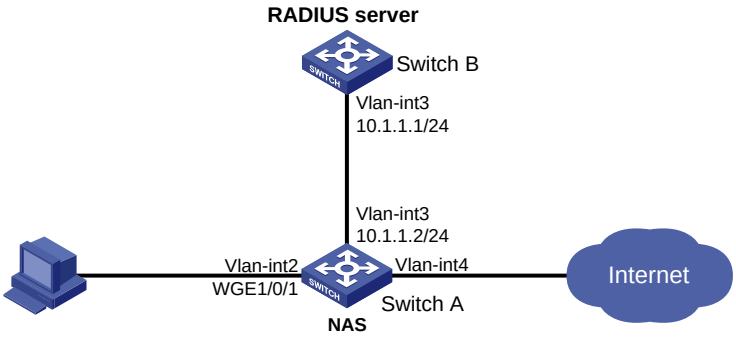
Network configuration



As shown in Figure 33, Switch B acts as the RADIUS server for authentication and authorization of 802.1X users connected to the NAS (Switch A).



Configure the switches to meet the following requirements:



- Perform 802.1X user authentication on GigabitEthernet 1/0/1 of the NAS.
- The shared key is **expert** and the authentication port is 1812.
- Exclude domain names from the usernames sent to the RADIUS server.
- The user name for 802.1X authentication is **dot1x**.
- After the user passes authentication, the RADIUS server authorizes VLAN 4 to the NAS port that the user is connecting to.

Vlan-int3
10.1.1.2/24
Vlan-int2
XGE1/1/1
Vlan-int4
Internet
Switch A
NAS
802.1X user

Procedure

1. Configure the NAS:

   a. Configure a RADIUS scheme:

   # Configure a RADIUS scheme named **rad** and enter RADIUS scheme view.

   ```
   <SwitchA> system-view
   [SwitchA] radius scheme rad
   ```

   # Specify the primary authentication server with IP address 10.1.1.1 and set the shared key to **expert** in plaintext form.

   ```
   [SwitchA-radius-rad] primary authentication 10.1.1.1 key simple expert
   ```

   # Exclude domain names from the usernames sent to the RADIUS server.

   ```
   [SwitchA-radius-rad] user-name-format without-domain
   [SwitchA-radius-rad] quit
   ```

   b. Configure an ISP domain:

   # Create an ISP domain named **bbb** and enter ISP domain view.

   ```
   [SwitchA] domain bbb
   ```

   # Configure the ISP domain to use RADIUS scheme **rad** for authentication and authorization of LAN users and not to perform accounting for LAN users.

   ```
   [SwitchA-isp-bbb] authentication lan-access radius-scheme rad
   [SwitchA-isp-bbb] authorization lan-access radius-scheme rad
   [SwitchA-isp-bbb] accounting lan-access none
   [SwitchA-isp-bbb] quit
   ```

   c. Configure 802.1X authentication:

   # Enable 802.1X for GigabitEthernet 1/0/1.

   ```
   [SwitchA] interface gigabitethernet 1/0/1
   [SwitchA-GigabitEthernet1/0/1] dot1x
   ```

Specify **bbb** as the mandatory authentication domain for 802.1X users on the interface.

```
[SwitchA-GigabitEthernet1/0/1] dot1x mandatory-domain bbb
[SwitchA-GigabitEthernet1/0/1] quit
```

Enable 802.1X globally.

```
[SwitchA] dot1x
```

2. Configure the RADIUS server:

Create a network access user named **dot1x**.

```
<SwitchB> system-view
[SwitchB] local-user dot1x class network
```

Configure the password as **123456** in plaintext form.

```
[SwitchB-luser-network-dot1x] password simple 123456
```

Configure VLAN 4 as the authorization VLAN.

```
[SwitchB-luser-network-dot1x] authorization-attribute vlan 4
[SwitchB-luser-network-dot1x] quit
```

Configure the IP address of the RADIUS client as 10.1.1.2 and the shared key as **expert** in plaintext form.

```
[SwitchB] radius-server client ip 10.1.1.2 key simple expert
```

Activate the RADIUS server configuration.

```
[SwitchB] radius-server activate
```

Verifying the configuration

1. On the RADIUS server, display the activated RADIUS clients and users.

```
[SwitchB] display radius-server active-client
Total 1 RADIUS clients.
Client IP: 10.1.1.2
[SwitchB] display radius-server active-user dot1x
Total 1 RADIUS users matched.
Username: dot1x
  Description: Not configured
  Authorization attributes:
    VLAN ID: 4
    ACL number: Not configured
  Validity period:
    Expiration time: Not configured
```

2. On the host, use account **dot1x** for 802.1X authentication.

   If the host runs the Windows built-in 802.1X client, configure the network connection properties as follows:

   a. Click the **Authentication** tab of the properties window.

   b. Select the **Enable IEEE 802.1X authentication for this network** option.

   c. Select MD5 challenge as the EAP type.

   d. Click **OK**.

   If the host runs the iNode client, no advanced authentication options are required. The user passes authentication after entering the correct user name and password on the authentication page or the iNode client.

IMPORTANT:

Make sure the client can update its IP address to access the resources in the authorized VLAN after passing authentication.

3. On the NAS, verify that the RADIUS server assigns the port to VLAN 4 after the user passes authentication. (Details not shown.)
4. On the NAS, display online 802.1X user information.

```
[SwitchA] display dot1x connection
```

Troubleshooting AAA

RADIUS authentication failure

Symptom

User authentication always fails.

Analysis

Possible reasons include:

- A communication failure exists between the NAS and the RADIUS server.
- The username is not in the *userid@isp-name* format, or the ISP domain is not correctly configured on the NAS.
- The user is not configured on the RADIUS server.
- The password entered by the user is incorrect.
- The RADIUS server and the NAS are configured with different shared keys.

Solution

To resolve the problem:

1. Verify the following items:
   - The NAS and the RADIUS server can ping each other.
   - The username is in the *userid@isp-name* format and the ISP domain is correctly configured on the NAS.
   - The user is configured on the RADIUS server.
   - The correct password is entered.
   - The same shared key is configured on both the RADIUS server and the NAS.
2. If the problem persists, contact H3C Support.

RADIUS packet delivery failure

Symptom

RADIUS packets cannot reach the RADIUS server.

Analysis

Possible reasons include:

- A communication failure exists between the NAS and the RADIUS server.
- The NAS is not configured with the IP address of the RADIUS server.
- The authentication and accounting UDP ports configured on the NAS are incorrect.
- The RADIUS server's authentication and accounting port numbers are being used by other applications.

Solution

To resolve the problem:

1. Verify the following items:
   - The link between the NAS and the RADIUS server works well at both the physical and data link layers.
   - The IP address of the RADIUS server is correctly configured on the NAS.
   - The authentication and accounting UDP port numbers configured on the NAS are the same as those of the RADIUS server.
   - The RADIUS server's authentication and accounting port numbers are available.
2. If the problem persists, contact H3C Support.

RADIUS accounting error

Symptom

A user is authenticated and authorized, but accounting for the user is not normal.

Analysis

The accounting server configuration on the NAS is not correct. Possible reasons include:

- The accounting port number configured on the NAS is incorrect.
- The accounting server IP address configured on the NAS is incorrect. For example, the NAS is configured to use a single server to provide authentication, authorization, and accounting services, but in fact the services are provided by different servers.

Solution

To resolve the problem:

1. Verify the following items:
   - The accounting port number is correctly configured.
   - The accounting server IP address is correctly configured on the NAS.
2. If the problem persists, contact H3C Support.

Troubleshooting HWTACACS

Similar to RADIUS troubleshooting. See "RADIUS authentication failure," "RADIUS packet delivery failure," and "RADIUS accounting error."

LDAP authentication failure

Symptom

User authentication fails.

Analysis

Possible reasons include:

- A communication failure exists between the NAS and the LDAP server.
- The LDAP server IP address or port number configured on the NAS is not correct.
- The username is not in the *userid@isp-name* format, or the ISP domain is not correctly configured on the NAS.
- The user is not configured on the LDAP server.
- The password entered by the user is incorrect.
- The administrator DN or password is not configured.

- Some user attributes (for example, the username attribute) configured on the NAS are not consistent with those configured on the server.
- No user search base DN is specified for the LDAP scheme.

Solution

To resolve the problem:

1. Verify the following items:
   - The NAS and the LDAP server can ping each other.
   - The IP address and port number of the LDAP server configured on the NAS match those of the server.
   - The username is in the correct format and the ISP domain for the user authentication is correctly configured on the NAS.
   - The user is configured on the LDAP server.
   - The correct password is entered.
   - The administrator DN and the administrator password are correctly configured.
   - The user attributes (for example, the username attribute) configured on the NAS are consistent with those configured on the LDAP server.
   - The user search base DN for authentication is specified.
2. If the problem persists, contact H3C Support.

Appendixes

Appendix A Commonly used RADIUS attributes

Commonly used RADIUS attributes are defined in RFC 2865, RFC 2866, RFC 2867, and RFC 2868.

Table 5 Commonly used RADIUS attributes

No.	Attribute	No.	Attribute
1	User-Name	45	Acct-Authentic
2	User-Password	46	Acct-Session-Time
3	CHAP-Password	47	Acct-Input-Packets
4	NAS-IP-Address	48	Acct-Output-Packets
5	NAS-Port	49	Acct-Terminate-Cause
6	Service-Type	50	Acct-Multi-Session-Id
7	Framed-Protocol	51	Acct-Link-Count
8	Framed-IP-Address	52	Acct-Input-Gigawords
9	Framed-IP-Netmask	53	Acct-Output-Gigawords
10	Framed-Routing	54	(unassigned)
11	Filter-ID	55	Event-Timestamp
12	Framed-MTU	56-59	(unassigned)
13	Framed-Compression	60	CHAP-Challenge
14	Login-IP-Host	61	NAS-Port-Type
15	Login-Service	62	Port-Limit

No.	Attribute	No.	Attribute
16	Login-TCP-Port	63	Login-LAT-Port
17	(unassigned)	64	Tunnel-Type
18	Reply-Message	65	Tunnel-Medium-Type
19	Callback-Number	66	Tunnel-Client-Endpoint
20	Callback-ID	67	Tunnel-Server-Endpoint
21	(unassigned)	68	Acct-Tunnel-Connection
22	Framed-Route	69	Tunnel-Password

44	Acct-Session-Id	91	Tunnel-Server-Auth-id

Appendix B Descriptions for commonly used standard RADIUS attributes

No.	Attribute	Description
1	User-Name	Name of the user to be authenticated.
2	User-Password	User password for PAP authentication, only present in Access-Request packets when PAP authentication is used.

No.	Attribute	Description
3	CHAP-Password	Digest of the user password for CHAP authentication, only present in Access-Request packets when CHAP authentication is used.
4	NAS-IP-Address	IP address for the server to use to identify the client. Typically, a client is identified by the IP address of its access interface. This attribute is only present in Access-Request packets.
5	NAS-Port	Physical port of the NAS that the user accesses.
6	Service-Type	Type of service that the user has requested or type of service to be provided.
7	Framed-Protocol	Encapsulation protocol for framed access.
8	Framed-IP-Address	IP address assigned to the user.
11	Filter-ID	Name of the filter list. If the name starts with a digit, it indicates an ACL number.
12	Framed-MTU	MTU for the data link between the user and NAS. For example, this attribute can be used to define the maximum size of EAP packets allowed to be processed in 802.1X EAP authentication.
14	Login-IP-Host	IP address of the NAS interface that the user accesses.
15	Login-Service	Type of service that the user uses for login.
18	Reply-Message	Text to be displayed to the user, which can be used by the server to communicate information, for example, the cause of the authentication failure.
26	Vendor-Specific	Vendor-specific proprietary attribute. A packet can contain one or more proprietary attributes, each of which can contain one or more subattributes.
27	Session-Timeout	Maximum service duration for the user before termination of the session.
28	Idle-Timeout	Maximum idle time permitted for the user before termination of the session.
31	Calling-Station-Id	User identification that the NAS sends to the server. For the LAN access service provided by an H3C device, this attribute includes the MAC address of the user.
32	NAS-Identifier	Identification that the NAS uses to identify itself to the RADIUS server.
40	Acct-Status-Type	Type of the Accounting-Request packet. Possible values include: • **1**—Start. • **2**—Stop. • **3**—Interim-Update. • **4**—Reset-Charge. • **7**—Accounting-On. (Defined in the 3rd Generation Partnership Project.) • **8**—Accounting-Off. (Defined in the 3rd Generation Partnership Project.) • **9 to 14**—Reserved for tunnel accounting. • **15**—Reserved for failed.
45	Acct-Authentic	Authentication method used by the user. Possible values include: • **1**—RADIUS. • **2**—Local. • **3**—Remote.

No.	Attribute	Description
60	CHAP-Challenge	CHAP challenge generated by the NAS for MD5 calculation during CHAP authentication.
61	NAS-Port-Type	Type of the physical port of the NAS that is authenticating the user. Possible values include: • **15**—Ethernet. • **16**—Any type of ADSL. • **17**—Cable. (With cable for cable TV.) • **19**—WLAN-IEEE 802.11. • **201**—VLAN. • **202**—ATM. If the port is an ATM or Ethernet one and VLANs are implemented on it, the value of this attribute is 201.
64	Tunnel-Type	Tunneling protocols used. The value **13** represents VLAN. If the value is 13, the device interprets the Tunnel-Type, Tunnel-Medium-Type, and Tunnel-Private-Group-ID attributes as attributes to assign VLANs.
65	Tunnel-Medium-Type	Transport medium type to use for creating a tunnel. For VLAN assignment, the value must be **6** to indicate the 802 media plus Ethernet.
79	EAP-Message	Used to encapsulate EAP packets to allow RADIUS to support EAP authentication.
80	Message-Authenticator	Used for authentication and verification of authentication packets to prevent spoofing Access-Requests. This attribute is present when EAP authentication is used.
81	Tunnel-Private-Group-ID	Group ID for a tunnel session. To assign VLANs, the NAS conveys VLAN IDs by using this attribute.
87	NAS-Port-Id	String for describing the port of the NAS that is authenticating the user.
168	Framed-IPv6-Address	Server-assigned IPv6 address for the NAS to assign to the host. The address must be unique.

Appendix C RADIUS subattributes (vendor ID 25506)

Table 6 lists all RADIUS subattributes with a vendor ID of 25506. Support for these subattributes depends on the device model.

Table 6 RADIUS subattributes (vendor ID 25506)

No.	Subattribute	Description
1	Input-Peak-Rate	Peak rate in the direction from the user to the NAS, in bps.
2	Input-Average-Rate	Average rate in the direction from the user to the NAS, in bps.
3	Input-Basic-Rate	Basic rate in the direction from the user to the NAS, in bps.
4	Output-Peak-Rate	Peak rate in the direction from the NAS to the user, in bps.
5	Output-Average-Rate	Average rate in the direction from the NAS to the user, in bps.
6	Output-Basic-Rate	Basic rate in the direction from the NAS to the user, in bps.
15	Remanent_Volume	Total amount of data available for the connection, in different units for different server types.

No.	Subattribute	Description
17	ISP-ID	ISP domain where the user obtains authorization information.
20	Command	Operation for the session, used for session control. Possible values include: • **1**—Trigger-Request. • **2**—Terminate-Request. • **3**—SetPolicy. • **4**—Result. • **5**—PortalClear.
25	Result_Code	Result of the Trigger-Request or SetPolicy operation, zero for success and any other value for failure.
26	Connect_ID	Index of the user connection.
27	PortalURL	PADM redirect URL assigned to PPPoE users.
28	Ftp_Directory	FTP, SFTP, or SCP user working directory. When the RADIUS client acts as the FTP, SFTP, or SCP server, this attribute is used to set the working directory for an FTP, SFTP, or SCP user on the RADIUS client.
29	Exec_Privilege	EXEC user priority.
32	NAT-IP-Address	Public IP address assigned to the user when the source IP address and port are translated.
33	NAT-Start-Port	Start port number of the port range assigned to the user when the source IP address and port are translated.
34	NAT-End-Port	End port number of the port range assigned to the user when the source IP address and port are translated.
59	NAS_Startup_Timestamp	Startup time of the NAS in seconds, which is represented by the time elapsed after 00:00:00 on Jan. 1, 1970 (UTC).
60	Ip_Host_Addr	User IP address and MAC address included in authentication and accounting requests, in the format A.B.C.D hh:hh:hh:hh:hh:hh. A space is required between the IP address and the MAC address.
61	User_Notify	Information that must be sent from the server to the client transparently.
62	User_HeartBeat	Hash value assigned after an 802.1X user passes authentication, which is a 32-byte string. This attribute is stored in the user list on the NAS and verifies the handshake packets from the 802.1X user. This attribute only exists in Access-Accept and Accounting-Request packets.
98	Multicast_Receive_Group	IP address of the multicast group that the user's host joins as a receiver. This subattribute can appear multiple times in a multicast packet to indicate that the user belongs to multiple multicast groups.
100	IP6_Multicast_Receive_Group	IPv6 address of the multicast group that the user's host joins as a receiver. This subattribute can appear multiple times in a multicast packet to indicate that the user belongs to multiple multicast groups.
101	MLD-Access-Limit	Maximum number of MLD multicast groups that the user can join concurrently.
102	local-name	L2TP local tunnel name.
103	IGMP-Access-Limit	Maximum number of IGMP multicast groups that the user can join concurrently.

No.	Subattribute	Description
104	VPN-Instance	MPLS L3VPN instance to which a user belongs.
105	ANCP-Profile	ANCP profile name.
135	Client-Primary-DNS	IP address of the primary DNS server.
136	Client-Secondary-DNS	IP address of the secondary DNS server.
140	User_Group	User groups assigned after the user passes authentication. Typically, a user can belong to only one user group.
144	Acct_IPv6_Input_Octets	Bytes of IPv6 packets in the inbound direction. The measurement unit depends on the configuration on the device.
145	Acct_IPv6_Output_Octets	Bytes of IPv6 packets in the outbound direction. The measurement unit depends on the configuration on the device.
146	Acct_IPv6_Input_Packets	Number of IPv6 packets in the inbound direction. The measurement unit depends on the configuration on the device.
147	Acct_IPv6_Output_Packets	Number of IPv6 packets in the outbound direction. The measurement unit depends on the configuration on the device.
148	Acct_IPv6_Input_Gigawords	Bytes of IPv6 packets in the inbound direction. The measurement unit is 4G bytes.
149	Acct_IPv6_Output_Gigawords	Bytes of IPv6 packets in the outbound direction. The measurement unit is 4G bytes.
155	User-Roles	List of space-separated user roles.
182	Microsegment-Id	Microsegment ID.
210	Av-Pair	User-defined attribute pair. Available attribute pairs include: • Server-assigned voice VLAN in the format of device-traffic-class=voice. • Server-assigned user role in the format of shell:role=xxx. • Server-assigned ACL in the format of url-redirect-acl=xxx. • Server-assigned IPv4 Web redirect URL in the format of url-redirect=xxx. • Server-assigned IPv6 Web redirect URL in the format of urlipv6-redirect=xxx. • Server-deployed command to reboot a port, in the format of subscriber:command=bounce-host-port. • Server-assigned port shutdown duration in the format of bounce:seconds=xxx. • Server-deployed command to shut down a port, in the format of subscriber:command=disable-host-port. • Server-assigned blackhole MAC address attribute in the format of mac:block-mac=xxx. • Server-assigned MAC authentication offline detect timer (in seconds) in the format of mac-authentication: offline-detect-time=xxx. Value 0 of xxx indicates that MAC authentication offline detection is disabled. • Server-assigned MAC authentication offline detection flag in the format of mac-authentication: offline-detect-check=x. x has the following values: ○ **0**—The device does not search for the ARP snooping entry or ND snooping entry of the MAC address. ○ **1**—The device searches for the ARP snooping entry or ND snooping entry of the MAC address. • Server-assigned dynamic ACL. For more information about

No.	Subattribute	Description
		the format of this attribute, see "Appendix D Format of dynamic authorization ACLs." Support for this attribute in 802.1X authentication and MAC authentication depends on the device model. If the server assigns a user both this attribute and the Filter-ID attribute, the device will ignore this attribute. The device does not support using CoA messages to change the content assigned by this attribute or assign another ACL to the user.
230	NAS-Port-Name	Interface through which the user is connected to the NAS.
246	Auth_Detail_Result	Accounting details. The server sends Access-Accept packets with subattributes 246 and 250 in the following situations: • **1**—The subscriber charge is overdue. The subscriber is allowed to access network resources in the whitelist. If the subscriber accesses other network resources, the device redirects it to the URL specified by subattribute 250. • **2**—The broadband lease of the subscriber expires. The device redirects the subscriber to the URL specified by subattribute 250 when the subscriber requests to access webpages for the first time.
247	Input-Committed-Burst-Size	Committed burst size from the user to the NAS, in bits. The total length cannot exceed 4 bytes for this field. This subattribute must be assigned together with the Input-Average-Rate attribute.
248	Output-Committed-Burst-Size	Committed burst size from the NAS to the user, in bits. The total length cannot exceed 4 bytes for this field. This subattribute must be assigned together with the Output-Average-Rate attribute.
249	authentication-type	Authentication type. The value can be: • **1**—Intranet access authentication. • **2**—Internet access authentication. If the packet does not contain this subattribute, common authentication applies.
250	WEB-URL	Redirect URL for users. In single-stack scenarios, use this attribute to assign the authorized IPv4 URL or IPv6 URL. In dual-stack scenarios, use this attribute to assign the authorized IPv4 URL and use user-defined attribute pair **urlipv6-redirect** to assign the authorized IPv6 URL.
251	Subscriber-ID	Family plan ID.
252	Subscriber-Profile	QoS policy name for the family plan of the subscriber.
255	Product_ID	Product name.

Appendix D Format of dynamic authorization ACLs

Vendor ID 25506

The server might assign a dynamic authorization ACL that contains multiple rules to a user in different ways:

- Assign only one Av-Pair subattribute to the user. In this subattribute, the dynamic ACL contains multiple rules separated by question marks (?).

- Assign multiple Av-Pair subattributes to the user. All the subattributes contain the same dynamic ACL and a different rule. Support for this method depends on the server model.

The format of a dynamic ACL rule is as follows:

aclrule?same?*acl-name*?*acl-type*?*ver-type*?*rule-id*?protocol=*protocol-type*?counting?dst-ip=*ip-addr* ?src-ip=*ip-addr*?dst-port=*port-value*?src-port=*port-value*?action=*action-type*

The fields in the rule are described in Table 7. The following is an example of a dynamic ACL rule:

aclrule?same?test?1?1?1?protocol=3?counting?dst-ip=1.1.1.1/1.1.1.1?src-ip=1.1.1.1/0?dst-port=1 .2000?src-port=5.2000-3000?action=1

Table 7 Fields in a dynamic ACL rule

Field	Description	Remarks
aclrule	Indicates that the following part is information about a dynamic ACL rule.	Required
same	Indicates that the current user will inherit the dynamic ACL rules that have been successfully assigned to another authenticated user. If the server assigns one user the same dynamic ACL as another user but the rules are different for the two users, the device applies the dynamic ACL rules of the user that comes online first to the other user.	Required
acl-name	ACL name, a case-insensitive string of 1 to 63 characters. The ACL name must begin with a letter and it cannot be **all** or the same as an existing static ACL on the device.	Required
acl-type	ACL type. **1** indicates an advanced ACL. In the current software version, only advanced ACLs are supported.	Required
ver-type	IP protocol type: • **1**—IPv4. • **2**—IPv6.	Required
rule-id	ACL rule number, in the range of 0 to 65534.	Required
protocol-type	Protocol type: • **1**—IP. • **2**—ICMP. • **3**—TCP. • **4**—UDP. • **5**—ICMPv6. • **6**—IPv6.	Optional
counting	Indicates that rule match statistics is enabled. If a rule does not include this field, rule match statistics is disabled for the rule.	Optional
ip-addr	IP address information. An IPv4 address must be in the format of X.X.X.X/X.X.X.X or X.X.X.X/0. Non-host IPv4 addresses can only be in the X.X.X.X/X.X.X.X format. An IPv6 address must be in the format of X:X::X:X/M. For example, 1.1.1.1/1.1.1.1, 1.1.1.1/0, or 3::3/128. If the value is **any**, the rule matches any IP address.	Optional
port-value	TCP or UDP port information, in the *X.YYY* format. • ***X***—Operator. ○ **1**—Equal to. ○ **2**—Greater than. ○ **3**—Smaller than. ○ **4**—Not equal to.	Optional

Field	Description	Remarks
	○ **5**—In the range of. • ***YYY***—Port number information. For example, 1.3000 and 5.2000-3000.	
action-type	Action type: • **1**—Deny. • **2**—Permit.	Optional

The following restrictions apply to dynamic authorization ACLs:

- For the former six fields (aclrule?same?*acl-name*?*acl-type*?*ver-type*?*rule-id*) of a dynamic ACL rule, their positions are fixed. The device cannot interpret a dynamic ACL rule if the positions of the six fields are changed. For the other fields, position changes are allowed.
- The settings for all the fields in the rules must meet the configuration logic of ACL rules on the device so the device can correctly interpret the rules.
- All dynamic ACL rules in one authorization must belong to the same ACL name.
- A dynamic ACL must have rules and the format of the rules must be valid.

Vendor ID 9

The server might assign a dynamic ACL to a user by using the CISCO-AV-Pair subattribute (vendor ID 9). The formats of the subattribute are as follows:

- **CiscoSecure-Defined-ACL=#ACSACL#-IP-***name***-***number*

  The *name* argument represents the ACL name and the *number* argument represents the version number.

  For example: **CiscoSecure-Defined-ACL=#ACSACL#-IP-UACL-0**.

- **ip:inacl#***number***=***rule*

  The *number* argument represents the ACL rule number and the *rule* argument represents the rule content.

  For example: **ip:inacl#1=permit udp any any eq 21862**.

Currently, only some device models support the CISCO-AV-Pair subattribute for 802.1X and MAC authentication. If the RADIUS server assigns dynamic ACLs to a user by using both the CISCO-AV-Pair (vendor ID 9) and Av-Pair (vendor ID 25506) subattributes, the device ignores the CISCO-AV-Pair subattribute.

The server assigns a dynamic ACL to a user as follows:

1. The server assigns a dynamic ACL name to a user by using the CISCO-AV-Pair subattribute in the format of **CiscoSecure-Defined-ACL=#ACSACL#-IP-***name***-***number* after the user passes authentication.
2. The device uses the dynamic ACL name as the username of the user to initiate authentication again.
3. The server assigns one or multiple ACL rules to the user by using the CISCO-AV-Pair subattribute in the format of **ip:inacl#***number***=***rule* after the user passes authentication.
4. The device parses the ACL rules received from the server, creates the ACL and its rules, and deploys the ACL and its rules to the user.

   In the current software version, the device can parse only the dynamic ACL rules in the following formats:

   { **deny** | **permit** } *protocol* [**destination** { *dest-address dest-wildcard* | **any** } | **destination-port** *operator port1* [*port2*] | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port1* [*port2*]]

The value for the *operator* argument can be **lt** (lower than), **gt** (greater than), **eq** (equal to), or **neq** (not equal to).

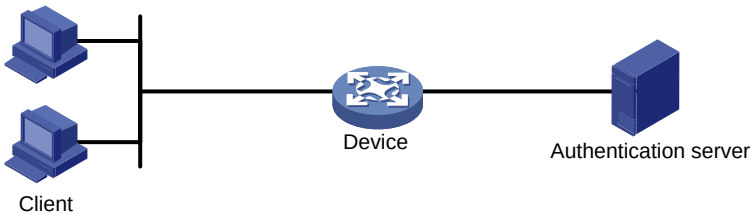
802.1X overview

About the 802.1X protocol



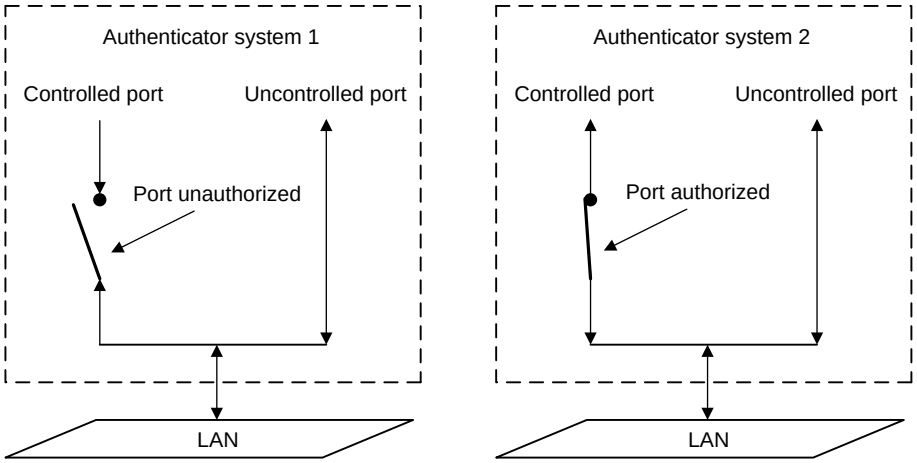
802.1X is a port-based network access control protocol widely used on Ethernet networks. The protocol controls network access by authenticating the devices connected to 802.1X-enabled LAN ports.

802.1X architecture

802.1X operates in the client/server model. As shown in Figure 1, 802.1X authentication includes the following entities:

- **Client (supplicant)**—A user terminal seeking access to the LAN. The terminal must have 802.1X software to authenticate to the access device.
- **Access device (authenticator)**—Authenticates the client to control access to the LAN. In a typical 802.1X environment, the access device uses an authentication server to perform authentication.
- **Authentication server**—Provides authentication services for the access device. The authentication server first authenticates 802.1X clients by using the data sent from the access device. Then, the server returns the authentication results to the access device to make access decisions. The authentication server is typically a RADIUS server. In a small LAN, you can use the access device as the authentication server.

Figure 1 802.1X architecture



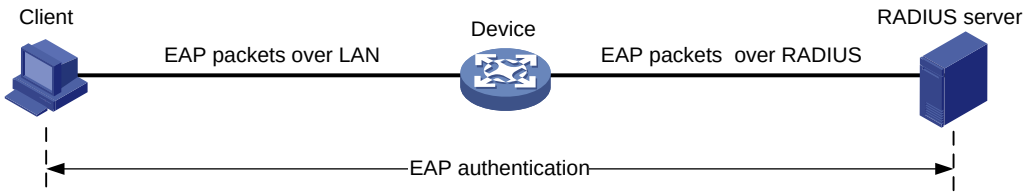
Controlled/uncontrolled port and port authorization status

802.1X defines two logical ports for the network access port: controlled port and uncontrolled port. Any packet arriving at the network access port is visible to both logical ports.

- **Uncontrolled port**—Is always open to receive and transmit authentication packets.
- **Controlled port**—Filters packets depending on the port state.
  - **Authorized state**—The controlled port is in authorized state when the client has passed authentication. The port allows traffic to pass through.
  - **Unauthorized state**—The port is in unauthorized state when the client has failed authentication. The port controls traffic by using one of the following methods:
    - Performs bidirectional traffic control to deny traffic to and from the client.
    - Performs unidirectional traffic control to deny traffic from the client. The device supports only unidirectional traffic control.

Figure 2 Authorization state of a controlled port

Packet exchange methods



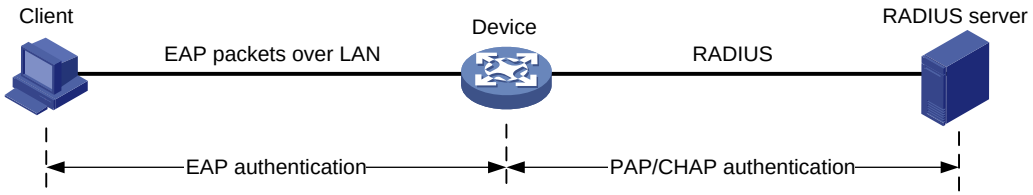
802.1X uses the Extensible Authentication Protocol (EAP) to transport authentication information for the client, the access device, and the authentication server. EAP is an authentication framework that uses the client/server model. The framework supports a variety of authentication methods, including MD5-Challenge, EAP-Transport Layer Security (EAP-TLS), and Protected EAP (PEAP).

802.1X defines EAP over LAN (EAPOL) for passing EAP packets between the client and the access device over a wired or wireless LAN. Between the access device and the authentication server, 802.1X delivers authentication information by either EAP relay or EAP termination.

EAP relay

EAP relay is defined in IEEE 802.1X. In this mode, the network device uses EAP over RADIUS (EAPOR) packets to send authentication information to the RADIUS server, as shown in Figure 3.

Figure 3 EAP relay



In EAP relay mode, the client must use the same authentication method as the RADIUS server. On the access device, you only need to use the **dot1x authentication-method eap** command to enable EAP relay.

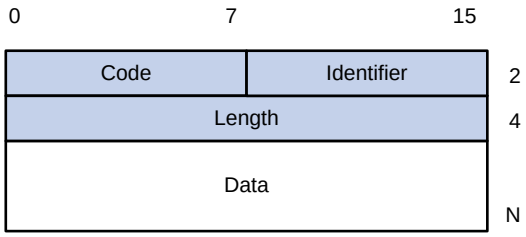
EAP termination

As shown in Figure 4, the access device performs the following operations in EAP termination mode:

1. Terminates the EAP packets received from the client.
2. Encapsulates the client authentication information in standard RADIUS packets.
3. Uses PAP or CHAP to authenticate to the RADIUS server.

Figure 4 EAP termination

Comparing EAP relay and EAP termination



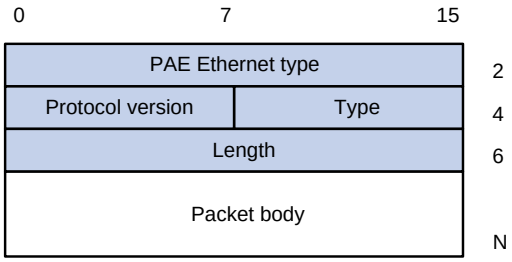
Packet exchange method	Benefits	Limitations
EAP relay	• Supports various EAP authentication methods. • The configuration and processing are simple on the access device.	The RADIUS server must support the EAP-Message and Message-Authenticator attributes, and the EAP authentication method used by the client.
EAP termination	Works with any RADIUS server that supports PAP or CHAP authentication.	• Supports only the following EAP authentication methods: ○ MD5-Challenge EAP authentication. ○ The username and password EAP authentication initiated by an iNode 802.1X client. • The processing is complex on the access device.

Packet formats

EAP packet format

Figure 5 shows the EAP packet format.

Figure 5 EAP packet format



- **Code**—Type of the EAP packet. Options include Request (1), Response (2), Success (3), or Failure (4).
- **Identifier**—Used for matching Responses with Requests.
- **Length**—Length (in bytes) of the EAP packet. The EAP packet length is the sum of the Code, Identifier, Length, and Data fields.
- **Data**—Content of the EAP packet. This field appears only in a Request or Response EAP packet. The **Data** field contains the request type (or the response type) and the type data. Type 1 (Identity) and type 4 (MD5-Challenge) are two examples for the type field.

EAPOL packet format

Figure 6 shows the EAPOL packet format.

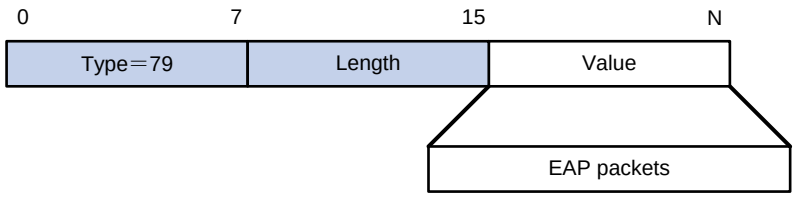
Figure 6 EAPOL packet format

- **PAE Ethernet type**—Protocol type. It takes the value 0x888E for EAPOL.
- **Protocol version**—The EAPOL protocol version used by the EAPOL packet sender.
- **Type**—Type of the EAPOL packet. Table 1 lists the types of EAPOL packets supported by the 802.1X implementation of the device.

  Table 1 Types of EAPOL packets

Value	Type	Description
0x00	EAP-Packet	The client and the access device uses EAP-Packets to transport authentication information.
0x01	EAPOL-Start	The client sends an EAPOL-Start message to initiate 802.1X authentication to the access device.
0x02	EAPOL-Logoff	The client sends an EAPOL-Logoff message to tell the access device that the client is logging off.

- **Length**—Data length in bytes, or length of the Packet body. If packet type is EAPOL-Start or EAPOL-Logoff, this field is set to 0, and no Packet body field follows.
- **Packet body**—Content of the packet. When the EAPOL packet type is EAP-Packet, the Packet body field contains an EAP packet.



EAP over RADIUS

RADIUS adds two attributes, EAP-Message and Message-Authenticator, for supporting EAP authentication. For the RADIUS packet format, see "Configuring AAA."

- EAP-Message.

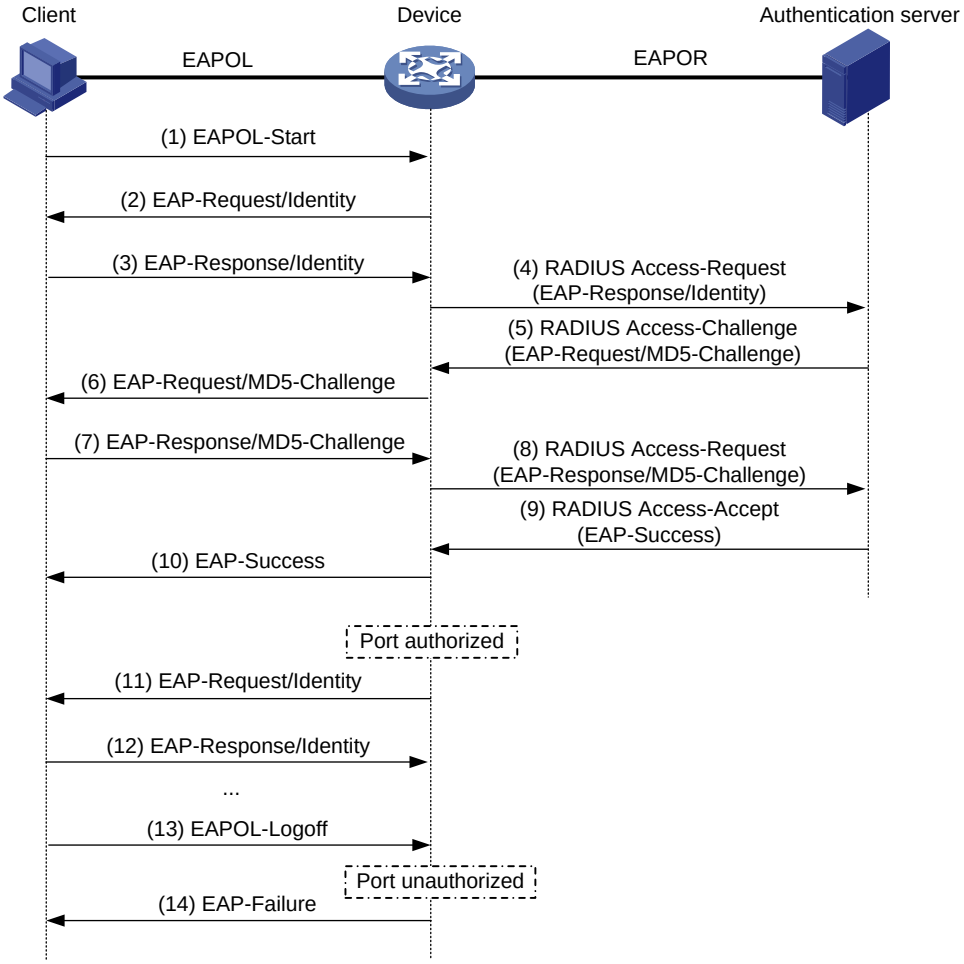
  RADIUS encapsulates EAP packets in the EAP-Message attribute, as shown in Figure 7. The Type field takes 79, and the Value field can be up to 253 bytes. If an EAP packet is longer than 253 bytes, RADIUS encapsulates it in multiple EAP-Message attributes.

  Figure 7 EAP-Message attribute format

- Message-Authenticator.

  As shown in Figure 8, RADIUS includes the Message-Authenticator attribute in all packets that have an EAP-Message attribute to check their integrity. The packet receiver drops the packet if the calculated packet integrity checksum is different from the Message-Authenticator attribute value. The Message-Authenticator prevents EAP authentication packets from being tampered with during EAP authentication.

Figure 8 Message-Authenticator attribute format



802.1X authentication procedures

802.1X authentication has two methods: EAP relay and EAP termination. You choose either mode depending on support of the RADIUS server for EAP packets and EAP authentication methods.

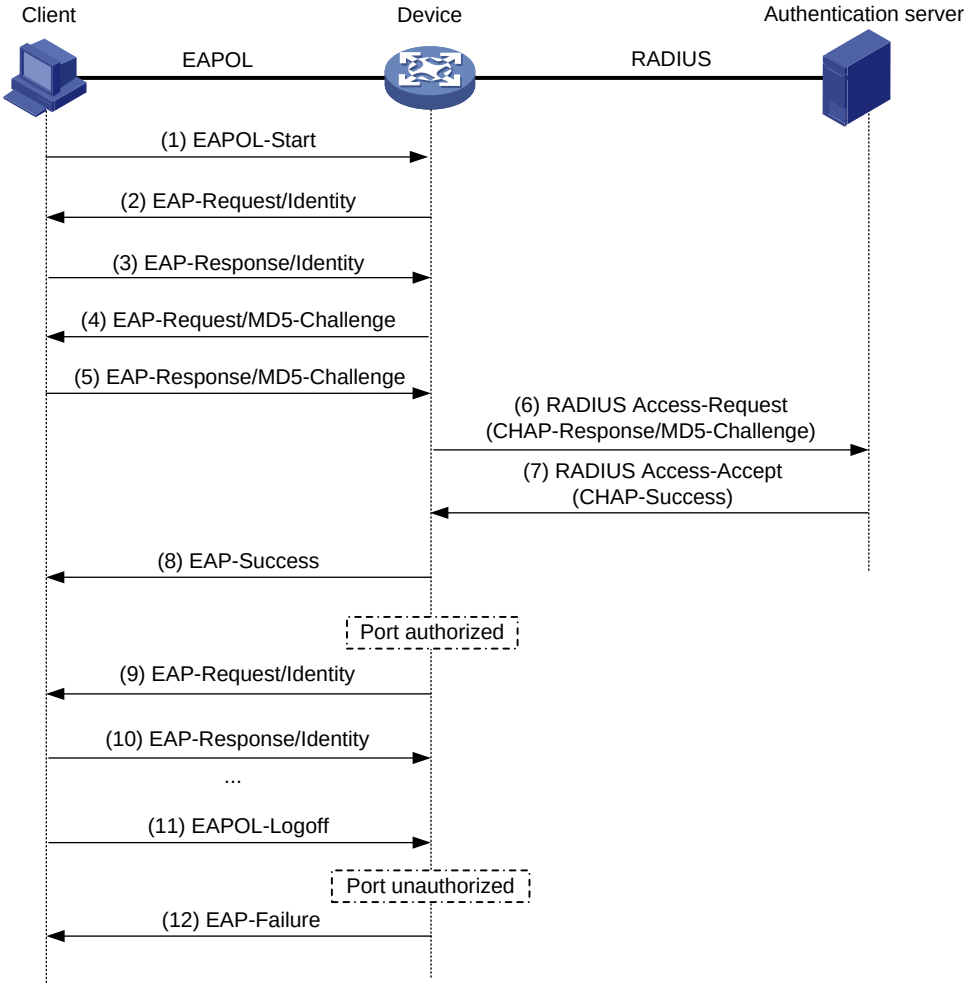
EAP relay

Figure 9 shows the basic 802.1X authentication procedure in EAP relay mode, assuming that MD5-Challenge EAP authentication is used.

Figure 9 802.1X authentication procedure in EAP relay mode

The following steps describe the 802.1X authentication procedure:

2. When a user launches the 802.1X client and enters a registered username and password, the 802.1X client sends an EAPOL-Start packet to the access device.
3. The access device responds with an EAP-Request/Identity packet to ask for the client username.
4. In response to the EAP-Request/Identity packet, the client sends the username in an EAP-Response/Identity packet to the access device.



5. The access device relays the EAP-Response/Identity packet in a RADIUS Access-Request packet to the authentication server.
6. The authentication server uses the identity information in the RADIUS Access-Request to search its user database. If a matching entry is found, the server uses a randomly generated challenge (EAP-Request/MD5-Challenge) to encrypt the password in the entry. Then, the server sends the challenge in a RADIUS Access-Challenge packet to the access device.
7. The access device transmits the EAP-Request/MD5-Challenge packet to the client.
8. The client uses the received challenge to encrypt the password, and sends the encrypted password in an EAP-Response/MD5-Challenge packet to the access device.
9. The access device relays the EAP-Response/MD5-Challenge packet in a RADIUS Access-Request packet to the authentication server.
10. The authentication server compares the received encrypted password with the encrypted password it generated at step 5. If the two passwords are identical, the server considers the client valid and sends a RADIUS Access-Accept packet to the access device.
11. Upon receiving the RADIUS Access-Accept packet, the access device performs the following operations:
    a. Sends an EAP-Success packet to the client.
    b. Sets the controlled port in authorized state.

    The client can access the network.
12. After the client comes online, the access device periodically sends handshake requests to check whether the client is still online. By default, if two consecutive handshake attempts fail, the device logs off the client.
13. Upon receiving a handshake request, the client returns a response. If the client fails to return a response after a number of consecutive handshake attempts (two by default), the access device logs off the client. This handshake mechanism enables timely release of the network resources used by 802.1X users that have abnormally gone offline.
14. The client can also send an EAPOL-Logoff packet to ask the access device for a logoff.
15. In response to the EAPOL-Logoff packet, the access device changes the status of the controlled port from authorized to unauthorized. Then, the access device sends an EAP-Failure packet to the client.

EAP termination

Figure 10 shows the basic 802.1X authentication procedure in EAP termination mode, assuming that CHAP authentication is used.

Figure 10 802.1X authentication procedure in EAP termination mode

In EAP termination mode, the access device rather than the authentication server generates an MD5 challenge for password encryption. The access device then sends the MD5 challenge together with the username and encrypted password in a standard RADIUS packet to the RADIUS server.

802.1X authentication initiation

Both the 802.1X client and the access device can initiate 802.1X authentication.

802.1X client as the initiator

The client sends an EAPOL-Start packet to the access device to initiate 802.1X authentication. The destination MAC address of the packet is the IEEE 802.1X specified multicast address 01-80-C2-00-00-03 or the broadcast MAC address. If any intermediate device between the client and the authentication server does not support the multicast address, you must use an 802.1X client that can send broadcast EAPOL-Start packets. For example, you can use the iNode 802.1X client.

Access device as the initiator

If the client cannot send EAPOL-Start packets, configure the access device to initiate authentication.

The access device supports the following modes:

- **Multicast trigger mode**—The access device multicasts EAP-Request/Identity packets to initiate 802.1X authentication at the identity request interval.

- **Unicast trigger mode**—Upon receiving a frame from an unknown MAC address, the access device sends an EAP-Request/Identity packet out of the receiving port to the MAC address. The device retransmits the packet if no response has been received within the identity request timeout interval. This process continues until the maximum number of request attempts set by using the **`dot1x retry`** command is reached.

The username request timeout timer sets both the identity request interval for the multicast trigger and the identity request timeout interval for the unicast trigger.

Access control methods

The device implements port-based access control as defined in the 802.1X protocol, and extends the protocol to support MAC-based access control.

- **Port-based access control**—Once an 802.1X user passes authentication on a port, any subsequent user can access the network through the port without authentication. When the authenticated user logs off, all other users are logged off.
- **MAC-based access control**—Each user is separately authenticated on a port. When a user logs off, no other online users are affected.

802.1X VLAN manipulation

Authorization VLAN

The authorization VLAN controls the access of an 802.1X user to authorized network resources. The device supports authorization VLANs assigned locally or by a remote server.

IMPORTANT:

Only remote servers can assign tagged authorization VLANs.

Remote VLAN authorization

In remote VLAN authorization, you must configure an authorization VLAN for a user on the remote server. After the user authenticates to the server, the server assigns authorization VLAN information to the device. Then, the device assigns the user access port to the authorization VLAN as a tagged or untagged member.

The device supports assignment of the following authorization VLAN information by the remote server:

- VLAN ID.
- VLAN name, which must be the same as the VLAN description on the access device.
- A string of VLAN IDs and VLAN names.

  In the string, some VLANs are represented by their IDs, and some VLANs are represented by their names.
- VLAN group name.

  For more information about VLAN groups, see *Layer 2—LAN Switching Configuration Guide*.
- VLAN ID with a suffix of **t** or **u**.

  The **t** and **u** suffixes require the device to assign the access port to the VLAN as a tagged or untagged member, respectively. For example, **2u** indicates assigning the port to VLAN 2 as an untagged member.

If a VLAN name or VLAN group name is assigned, the device converts the information into a VLAN ID before VLAN assignment.

IMPORTANT:

For a VLAN represented by its VLAN name to be assigned successfully, you must make sure the VLAN has been created on the device.

To assign VLAN IDs with suffixes, make sure the user access port is a hybrid or trunk port that performs port-based access control.

To ensure a successful assignment, the authorization VLANs assigned by the remote server cannot be any of the following types:

- Dynamically learned VLANs.
- Reserved VLANs.

If the server assigns a group of VLANs, the access device selects a VLAN as described in Table 2.

Table 2 Authorization VLAN selection from a group of VLANs

VLAN information	Authorization VLAN selection
VLANs by IDs VLANs by names VLAN group name	If the 802.1X-enabled port performs MAC-based access control, the device selects an authorization VLAN from the VLAN group for a user according to the following rules: • On a hybrid port with MAC-based VLAN enabled: ○ If the port does not have online users, the device selects the VLAN with the lowest ID. ○ If the port has online users, the device selects the VLAN that has the fewest online users. If two VLANs have the same number of online 802.1X users, the device selects the VLAN with the lower ID. • On an access, trunk, or MAC-based VLAN disabled hybrid port: ○ If the port does not have online users, the device selects the VLAN with the lowest ID. ○ If the port has online users, the device examines the VLAN group for the VLAN of the online users. If the VLAN is found, the VLAN is assigned to the user as the authorization VLAN. If the VLAN is not found, VLAN authorization fails. If the 802.1X-enabled port performs port-based access control, the device selects the VLAN with the lowest ID from the VLAN group. All subsequent 802.1X users are assigned to that VLAN.
VLAN IDs with suffixes	1. The device selects the leftmost VLAN ID without a suffix, or the leftmost VLAN ID suffixed by **u** as an untagged VLAN, whichever is more leftmost. 2. The device assigns the untagged VLAN to the port as the PVID, and it assigns the remaining as tagged VLANs. If no untagged VLAN is assigned, the PVID of the port does not change. The port permits traffic from these tagged and untagged VLANs to pass through. For example, the authentication server sends the string **1u 2t 3** to the access device for a user. The device assigns VLAN 1 as an untagged VLAN and all remaining VLANs (including VLAN 3) as tagged VLANs. VLAN 1 becomes the PVID.

Local VLAN authorization

To perform local VLAN authorization for a user, specify the VLAN ID in the authorization attribute list of the local user account for that user. For each local user, you can specify only one authorization VLAN ID. The user access port is assigned to the VLAN as an untagged member.

IMPORTANT:

Local VLAN authorization does not support assignment of tagged VLANs.

For more information about local user configuration, see "Configuring AAA."

Authorization VLAN manipulation on an 802.1X-enabled port

Table 3 describes how the access device handles VLANs (except for the VLANs specified with suffixes) on an 802.1X-enabled port.

Table 3 VLAN manipulation

Port access control method	Access port	Trunk port	Hybrid port
Port-based	Make sure the authorization VLAN assigned by the server has the untagged attribute. VLAN assignment will fail if the server issues a VLAN that has the tagged attribute. The device assigns the port to the first authenticated user's authorization VLAN and sets the VLAN as the PVID if that authorization VLAN has the untagged attribute.	If the authorization VLAN has the untagged attribute, the device assigns the port to the authorization VLAN and sets the VLAN as the PVID. If the authorization VLAN has the tagged attribute, the device assigns the port to the VLAN without changing the PVID.	If the authorization VLAN has the untagged attribute, the device assigns the port to the authorization VLAN as an untagged member and sets the VLAN as the PVID. If the authorization VLAN has the tagged attribute, the device assigns the port to the VLAN as a tagged member without changing the PVID.
MAC-based	Make sure the authorization VLAN assigned by the server has the untagged attribute. VLAN assignment will fail if the server issues a VLAN that has the tagged attribute. The device assigns the port to the first authenticated user's authorization VLAN and sets the VLAN as the PVID if that authorization VLAN has the untagged attribute.	If the authorization VLAN has the untagged attribute, the device assigns the port to the authorization VLAN and sets the VLAN as the PVID. If the authorization VLAN has the tagged attribute, the device assigns the port to the VLAN without changing the PVID.	If the authorization VLAN has the untagged attribute, the device assigns the port to the authorization VLAN as an untagged member and sets the VLAN as the PVID. If the authorization VLAN has the tagged attribute, the device assigns the port to the VLAN as a tagged member without changing the PVID. On a hybrid port with MAC-based VLAN enabled, if an untagged VLAN is assigned to a user, the device dynamically creates a VLAN and MAC address mapping for the user, without changing the PVID of the port. On a hybrid port with MAC-based VLAN disabled, the device assigns the port to the first authenticated user's authorization VLAN and sets that VLAN as the PVID if it has the untagged attribute.
	IMPORTANT: Always assign the same untagged VLAN to users on a port if the port is an access port, trunk port, or hybrid port with MAC MAC-based VLAN disabled. You can assign different untagged VLANs to different users only on a hybrid port with MAC-based VLAN enabled. After a user passes authentication and comes online with an untagged authorization VLAN, any subsequent users will be unable to pass authentication if they are assigned a different authorization VLAN. You can assign different tagged VLANs to different users, whether or not MAC-based		

Port access control method	Access port	Trunk port	Hybrid port
	VLAN is enabled. The device allows one tagged VLAN to be assigned to only one user.		

The VLAN assigned by the server to a user as an authorization VLAN might have been configured on the user access port but with a different tagging mode. For example, the server assigns an authorization VLAN with the tagged attribute, but the same VLAN configured on the port has the untagged attribute. In this situation, the VLAN settings that take effect on the user depend on the link type of the port.

- If the link type of the port is access or trunk, the authorization VLAN settings assigned by the server always take effect on the user as long as the user is online. After the user goes offline, the VLAN settings on the port take effect.
- If the link type of the port is hybrid, the VLAN settings configured on the port take effect. For example, the server assigns VLAN 30 with the untagged attribute to a user on the hybrid port. However, VLAN 30 has been configured on the port with the tagged attribute by using the **`port hybrid vlan tagged`** command. Then, the VLAN has the tagged attribute on the port.

For an 802.1X authenticated user to access the network on a hybrid port when no authorization VLAN is configured for the user, perform one of the following tasks:

- If the port receives tagged authentication packets from the user in a VLAN, use the **`port hybrid vlan`** command to configure the port as a tagged member in the VLAN.
- If the port receives untagged authentication packets from the user in a VLAN, use the **`port hybrid vlan`** command to configure the port as an untagged member in the VLAN.

On a port with periodic online user reauthentication enabled, the MAC-based VLAN feature does not take effect on a user that has been online since before this feature was enabled. The access device creates a MAC-to-VLAN mapping for the user when the following requirements are met:

- The user passes reauthentication.
- The authorization VLAN for the user is changed.

For more information about VLAN configuration and MAC-based VLANs, see *Layer 2—LAN Switching Configuration Guide*.

Guest VLAN

The 802.1X guest VLAN on a port accommodates users that have not performed 802.1X authentication. Users in the guest VLAN can access a limited set of network resources, such as a software server, to download antivirus software and system patches. Once a user in the guest VLAN passes 802.1X authentication, it is removed from the guest VLAN and can access authorized network resources.

The access device handles VLANs on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

Authentication status	VLAN manipulation
A user accesses the 802.1X-enabled port when the port is in auto state.	The device assigns the port to the 802.1X guest VLAN. All 802.1X users on this port can access only resources in the guest VLAN. The guest VLAN assignment varies by port link mode. For more information, see "Authorization VLAN manipulation on an 802.1X-enabled port."

Authentication status	VLAN manipulation
A user in the 802.1X guest VLAN fails 802.1X authentication.	If an 802.1X Auth-Fail VLAN is available, the device assigns the port to the Auth-Fail VLAN. All users on this port can access only resources in the Auth-Fail VLAN. If no Auth-Fail VLAN is configured, the port is still in the 802.1X guest VLAN. All users on the port are in the guest VLAN. For information about the 802.1X Auth-Fail VLAN, see "Auth-Fail VLAN."
A user in the 802.1X guest VLAN passes 802.1X authentication.	The device removes the port from the 802.1X guest VLAN and assigns the port to the authorization VLAN of the user. If the authentication server does not assign an authorization VLAN, the initial PVID of the port applies. The user and all subsequent 802.1X users are assigned to the initial port VLAN. After the user logs off, the port is assigned to the guest VLAN again. **NOTE:** The initial PVID of an 802.1X-enabled port refers to the PVID used by the port before the port is assigned to any 802.1X VLANs.

IMPORTANT:

When the port receives a packet with a VLAN tag, the packet will be forwarded within the tagged VLAN if the VLAN is not the guest VLAN.

MAC-based access control

Authentication status	VLAN manipulation
A user accesses the 802.1X-enabled port and has not performed 802.1X authentication.	The device creates a mapping between the MAC address of the user and the 802.1X guest VLAN. The user can access only resources in the guest VLAN.
A user in the 802.1X guest VLAN fails 802.1X authentication.	If an 802.1X Auth-Fail VLAN is available, the device remaps the MAC address of the user to the Auth-Fail VLAN. The user can access only resources in the Auth-Fail VLAN. If no 802.1X Auth-Fail VLAN is configured, the user is removed from the guest VLAN and added to the initial PVID.
A user in the 802.1X guest VLAN passes 802.1X authentication.	The device remaps the MAC address of the user to the authorization VLAN. If the authentication server does not assign an authorization VLAN, the device remaps the MAC address of the user to the initial PVID on the port.

Auth-Fail VLAN

The 802.1X Auth-Fail VLAN on a port accommodates users that have failed 802.1X authentication because of the failure to comply with the organization's security policy. For example, the VLAN accommodates users that have entered a wrong password. Users in the Auth-Fail VLAN can access a limited set of network resources, such as a software server, to download antivirus software and system patches.

The access device handles VLANs on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

Authentication status	VLAN manipulation
A user accesses the port and fails 802.1X authentication.	The device assigns the port to the Auth-Fail VLAN. All 802.1X users on this port can access only resources in the Auth-Fail VLAN. The Auth-Fail VLAN assignment varies by port link mode. For more information, see "Authorization VLAN manipulation on an 802.1X-enabled port."
A user in the 802.1X Auth-Fail VLAN fails 802.1X authentication.	The port is still in the Auth-Fail VLAN, and all 802.1X users on this port are in this VLAN.
A user in the 802.1X Auth-Fail VLAN passes 802.1X authentication.	The device assigns the port to the authorization VLAN of the user, and it removes the port from the Auth-Fail VLAN. If the authentication server does not assign an authorization VLAN, the initial PVID of the port applies. The user and all subsequent 802.1X users are assigned to the initial PVID. After the user logs off, the port is assigned to the guest VLAN. If no guest VLAN is configured, the port is assigned to the initial PVID of the port.

MAC-based access control

Authentication status	VLAN manipulation
A user accesses the port and fails 802.1X authentication.	The device maps the MAC address of the user to the 802.1X Auth-Fail VLAN. The user can access only resources in the Auth-Fail VLAN.
A user in the 802.1X Auth-Fail VLAN fails 802.1X authentication.	The user is still in the Auth-Fail VLAN.
A user in the 802.1X Auth-Fail VLAN passes 802.1X authentication.	The device remaps the MAC address of the user to the authorization VLAN. If the authentication server does not assign an authorization VLAN, the device remaps the MAC address of the user to the initial PVID on the port.

Critical VLAN

The 802.1X critical VLAN on a port accommodates 802.1X users that have failed authentication because none of the RADIUS servers in their ISP domain are reachable. Users in the critical VLAN can access a limited set of network resources depending on the configuration.

The critical VLAN feature takes effect when 802.1X authentication is performed only through RADIUS servers. If an 802.1X user fails local authentication after RADIUS authentication, the user is not assigned to the critical VLAN. For more information about the authentication methods, see "Configuring AAA."

The access device handles VLANs on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

Authentication status	VLAN manipulation
A user accesses the port and fails 802.1X authentication because all the RADIUS servers are unreachable. A user that has passed authentication fails reauthentication because all the RADIUS servers are unreachable, and the user is logged out of the device.	The device assigns the port to the critical VLAN. The 802.1X user and all subsequent 802.1X users on this port can access only resources in the 802.1X critical VLAN. The critical VLAN assignment varies by port link mode. For more information, see "Authorization VLAN manipulation on an 802.1X-enabled port."
A user in the 802.1X critical VLAN fails authentication because all the RADIUS servers are unreachable.	The port is still in the critical VLAN.
A user in the 802.1X critical VLAN fails authentication for any reason other than unreachable servers.	If an 802.1X Auth-Fail VLAN has been configured, the port is assigned to the Auth-Fail VLAN. If no 802.1X Auth-Fail VLAN is configured, the port is assigned to the initial PVID of the port.
A user in the 802.1X critical VLAN passes 802.1X authentication.	The device assigns the port to the authorization VLAN of the user, and it removes the port from the 802.1X critical VLAN. If the authentication server does not assign an authorization VLAN, the initial PVID of the port applies. The user and all subsequent 802.1X users are assigned to this port VLAN. After the user logs off, the port is assigned to the guest VLAN. If no 802.1X guest VLAN is configured, the initial PVID of the port is restored.

If the port is added to the critical VLAN because no RADIUS servers are reachable, the device performs the following operations after it detects a reachable RADIUS server:

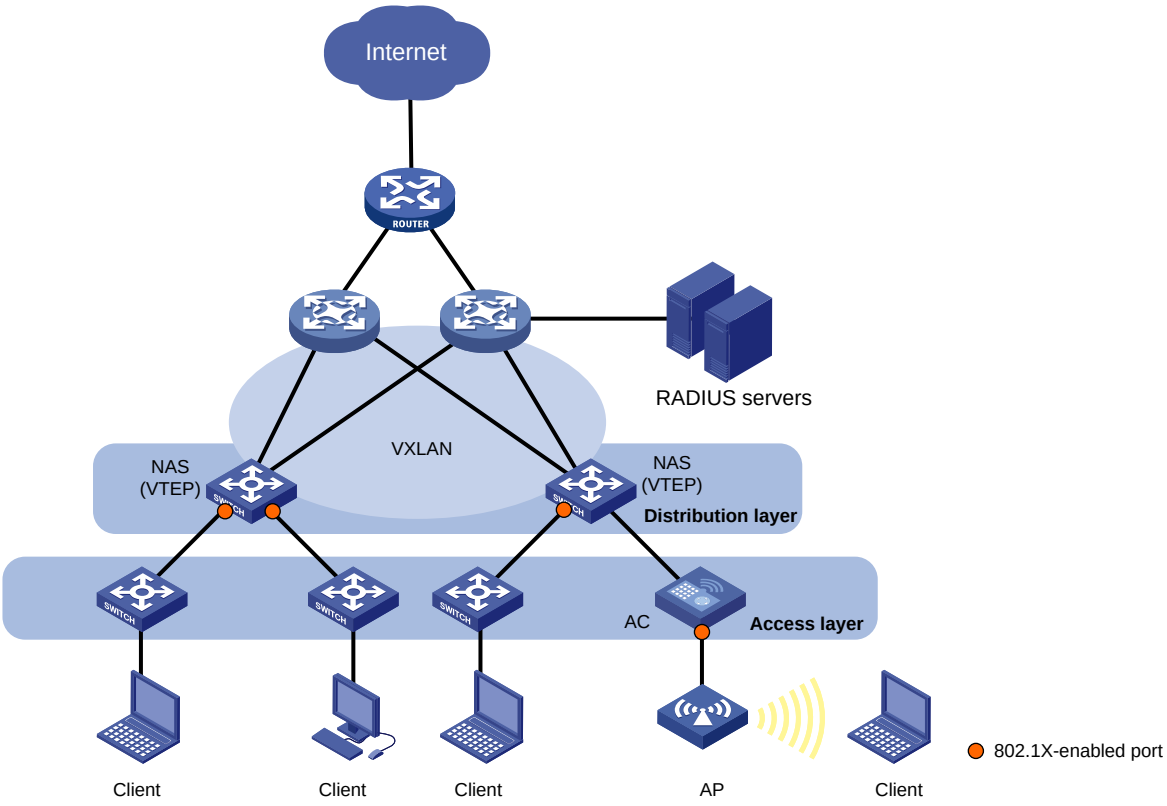
1. Removes the port from the critical VLAN.
2. Sends a multicast EAP-Request/Identity message out of the port to trigger authentication.

MAC-based access control

Authentication status	VLAN manipulation
A user accesses the port and fails 802.1X authentication because all the RADIUS servers are unreachable.	The device maps the MAC address of the user to the 802.1X critical VLAN. The user can access only resources in the 802.1X critical VLAN.
A user in the 802.1X critical VLAN fails authentication because all the RADIUS servers are unreachable.	The user is still in the critical VLAN.
A user in the 802.1X critical VLAN fails 802.1X authentication for any reason other than unreachable servers.	If an 802.1X Auth-Fail VLAN has been configured, the device remaps the MAC address of the user to the Auth-Fail VLAN ID. If no 802.1X Auth-Fail VLAN has been configured, the device remaps the MAC address of the user to the initial PVID.
A user in the 802.1X critical VLAN passes 802.1X authentication.	The device remaps the MAC address of the user to the authorization VLAN. If the authentication server does not assign an authorization VLAN to the user, the device remaps the MAC address of the user to the initial PVID on the port.

If a user is added to the critical VLAN because no RADIUS servers are reachable, the device performs the following operations after it detects a reachable RADIUS server:

1. Removes the user from the critical VLAN.
2. Sends a unicast EAP-Request/Identity message out of the port to the user for reauthentication.



802.1X VSI manipulation

802.1X support for VXLANs

As shown in Figure 11, when the device acts as both a VXLAN VTEP and a NAS, users' service information cannot be identified by VLANs. To resolve this issue, you must configure the RADIUS server to assign VSIs to authenticated 802.1X users. The NAS will map a user's traffic to the VXLAN that is associated with the user's authorization VSI. The mapping criteria include the user's access VLAN, access port, and MAC address. MAC address information is required only when the access port performs MAC-based access control.

For information about VSIs and VXLANs, see *VXLAN Configuration Guide*.

Figure 11 VXLAN network diagram for 802.1X authentication

Authorization VSI

An authorization VSI is associated with a VXLAN that has network resources inaccessible to unauthenticated users.

802.1X supports remote VSI authorization. If the VTEP does not receive authorization VSI information for an 802.1X user from the remote server, the user cannot access resources in any

VXLAN after passing authentication. If the VTEP receives authorization VSI information for a user from the remote server, it handles the authorization VSIs on an 802.1X-enabled port as shown in Table 4.

Table 4 VSI manipulation

Port access control method	VSI manipulation
Port-based	The VTEP dynamically creates an Ethernet service instance according to the user's access port and VLAN, and it maps the AC to the authorization VSI. Subsequent users in the same VLAN can access resources in the VXLAN associated with the VSI without authentication.
MAC-based	The VTEP dynamically creates an Ethernet service instance according to the user's access port, VLAN, and MAC address, and it then maps the AC to the authorization VSI. The user then can access resources in the VXLAN associated with the VSI.

For information about dynamic creation of Ethernet service instances, see *VXLAN configuration Guide*.

Guest VSI

The 802.1X guest VSI on a port accommodates users that have not performed 802.1X authentication. You can deploy a limited set of network resources in the VXLAN that is associated with the guest VSI. For example, deploy a software server for users to download anti-virus software and system patches. Once a user in the guest VSI passes 802.1X authentication, the user is removed from the guest VSI and can access authorized network resources.

The VTEP handles VSIs on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

Authentication status	VSI manipulation
A user accesses the port and has not performed 802.1X authentication.	The VTEP assigns the port to the 802.1X guest VSI. All 802.1X users from the same VLAN on this port can access only resources in the VXLAN associated with the guest VSI.
A user in the 802.1X guest VSI fails 802.1X authentication.	If an 802.1X Auth-Fail VSI is available (see "Auth-Fail VSI"), the VTEP assigns the port to the Auth-Fail VSI. All users from the same VLAN on this port can access only resources in the VXLAN associated with the Auth-Fail VSI. If no Auth-Fail VSI is configured, the port is still in the 802.1X guest VSI.
A user in the 802.1X guest VSI passes 802.1X authentication.	The VTEP removes the port from the 802.1X guest VSI and assigns the port to the authorization VSI of the user.

MAC-based access control

Authentication status	VSI manipulation
A user accesses the port and has not performed 802.1X authentication.	The VTEP maps the user's MAC address and access VLAN to the 802.1X guest VSI on the port. The user can access only resources in the VXLAN associated with the guest VSI.
A user in the 802.1X guest VSI fails 802.1X authentication.	If an 802.1X Auth-Fail VSI is available on the port, the VTEP remaps the user's MAC address and access VLAN to the Auth-Fail VSI. The user can access only resources in the VXLAN associated with the Auth-Fail VSI. If no 802.1X Auth-Fail VSI is configured on the port, the user is removed from the 802.1X guest VSI.
A user in the 802.1X guest VSI passes 802.1X authentication.	The VTEP removes the user from the 802.1X guest VSI and remaps the user's MAC address and access VLAN to the authorization VSI.

Auth-Fail VSI

The 802.1X Auth-Fail VSI on a port accommodates users that have failed 802.1X authentication because of the failure to comply with the organization's security policy. For example, the VSI accommodates users with wrong passwords entered. Users in the Auth-Fail VSI can access a limited set of network resources in the VXLAN associated with this VSI. You can deploy a software server in the Auth-Fail VSI for users to download antivirus software and system patches.

The VTEP handles VSIs on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

Authentication status	VSI manipulation
A user accesses the port and fails 802.1X authentication.	The VTEP assigns the port to the Auth-Fail VSI. All 802.1X users from the same VLAN on this port can access only resources in the VXLAN associated with the Auth-Fail VSI.
A user in the 802.1X Auth-Fail VSI fails 802.1X authentication because of any reason other than unreachable servers.	The port is still in the Auth-Fail VSI.
A user passes 802.1X authentication.	The VTEP removes the port from the Auth-Fail VSI and assigns the port to the authorization VSI of the user. After the user logs off, the port is removed from the authorization VSI. If the 802.1X guest VSI is configured on the port, the VTEP assigns the port to the guest VSI.

MAC-based access control

Authentication status	VSI manipulation
A user accesses the port and fails 802.1X authentication.	The VTEP maps the user's MAC address and access VLAN to the 802.1X Auth-Fail VSI on the port. The user can access only resources in the VXLAN associated with the Auth-Fail VSI.

Authentication status	VSI manipulation
A user in the 802.1X Auth-Fail VSI fails 802.1X authentication because of any reason other than unreachable servers.	The user is still in the Auth-Fail VSI.
A user in the 802.1X Auth-Fail VSI passes 802.1X authentication.	The VTEP removes the user from the 802.1X Auth-Fail VSI and remaps the user's MAC address and access VLAN to the authorization VSI.

Critical VSI

The 802.1X critical VSI on a port accommodates 802.1X users that have failed authentication because none of the RADIUS servers in their ISP domain are reachable. Users in the critical VSI can access a limited set of network resources in the VXLAN associated with this VSI.

The critical VSI feature takes effect when 802.1X authentication is performed only through RADIUS servers. If an 802.1X user fails local authentication after RADIUS authentication, the user is not assigned to the critical VSI. For more information about the authentication methods, see "Configuring AAA."

The VTEP handles VSIs on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

Authentication status	VSI manipulation
A user accesses the port and fails 802.1X authentication because all the RADIUS servers are unreachable.	The VTEP assigns the port to the critical VSI. The 802.1X user and all subsequent 802.1X users from the same VLAN on this port can access only resources in the VXLAN associated with the critical VSI.
A user in the 802.1X critical VSI fails authentication because all the RADIUS servers are unreachable.	The port is still in the critical VSI, and all 802.1X users from the same VLAN on this port are in the critical VSI.
A user in the 802.1X critical VSI fails authentication for any reason other than unreachable servers.	If an 802.1X Auth-Fail VSI has been configured for the port, the VTEP removes the port to the 802.1X Auth-Fail VSI. If no 802.1X Auth-Fail VSI is configured for the port, the VTEP logs off the user.
A user in the 802.1X critical VSI passes 802.1X authentication.	The VTEP removes the port from the 802.1X critical VSI and assigns the port to the authorization VSI. After the user logs off, the port is removed from the authorization VSI. If the port has been configured with the 802.1X guest VSI, the VTEP assigns the port to the guest VSI.

Authentication status	VSI manipulation
A user in the 802.1X guest VSI fails authentication because all the RADIUS servers are unreachable.	The VTEP assigns the port to the critical VSI. All 802.1X users on this port can access only resources in the VXLAN associated with the 802.1X critical VSI.
A user in the 802.1X Auth-Fail VSI fails authentication because all the RADIUS servers are unreachable.	The PVID of the port remains unchanged. All 802.1X users on this port can access only resources in the VXLAN associated with the 802.1X Auth-Fail VSI.
A user that has passed authentication fails reauthentication because all the RADIUS servers are unreachable, and the user is logged out of the device.	The VTEP assigns the port to the critical VSI.

MAC-based access control

Authentication status	VSI manipulation
A user accesses the port and fails 802.1X authentication because all the RADIUS servers are unreachable.	The VTEP maps the user's MAC address and access VLAN to the 802.1X critical VSI on the port. The user can access only resources in the VXLAN associated with the critical VSI.
A user in the 802.1X critical VSI fails authentication because all the RADIUS servers are unreachable.	The user is still in the critical VSI.
A user in the 802.1X critical VSI fails 802.1X authentication for any reason other than unreachable servers.	If an 802.1X Auth-Fail VSI has been configured on the port, the VTEP remaps the user's MAC address and access VLAN to the Auth-Fail VSI. If no 802.1X Auth-Fail VSI has been configured on the port, the VTEP logs off the user.
A user in the 802.1X critical VSI passes 802.1X authentication.	The VTEP remaps the user's MAC address and access VLAN to the authorization VSI.
A user in the 802.1X guest VSI fails authentication because all the RADIUS servers are unreachable.	The VTEP maps the user's MAC address and access VLAN to the 802.1X critical VSI on the port. The user can access only resources in the VXLAN associated with the critical VSI.
A user in the 802.1X Auth-Fail VSI fails authentication because all the RADIUS servers are unreachable.	The user remains in the 802.1X Auth-Fail VSI.

802.1X microsegment assignment

Authorization microsegment

A microsegment is a group of traffic that matches the same criteria. The microsegmentation feature provides group-based traffic control by applying policy to traffic on a per-microsegment basis. The RADIUS server can assign a microsegment to a user after that user passes 802.1X authentication. Then, the device performs microsegment-based traffic filtering for that user on the user's access port to make sure the user can access only the network resources available for the microsegment.

For more information about microsegmentation, see "Configuring microsegmentation."

IMPORTANT:

The following restrictions apply to 802.1X authentication on a microsegmented network:

- The server must assign an authorization ACL, redirect URL, and microsegment to an 802.1X user if that user must pass Web authentication.
- If the server assigns both an authorization ACL and an authorization microsegment to an 802.1X user that does not require Web authentication, only the authorization microsegment takes effect.

Critical microsegment

The 802.1X critical microsegment on a port accommodates users that have failed 802.1X authentication because no RADIUS authentication servers are reachable. Users in an 802.1X critical microsegment can access only network resources in the critical microsegment. The microsegment can belong to a VLAN or VXLAN.

The critical microsegment feature takes effect when 802.1X authentication is performed only through RADIUS servers. If an 802.1X user fails local authentication after RADIUS authentication, the user is not assigned to the critical microsegment. For more information about the authentication methods, see "Configuring AAA."

The access device handles users on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

The access device assigns or removes 802.1X users to or from the critical microsegment on a port depending on user authentication status, as shown in Table 5.

Table 5 Microsegment manipulation

Authentication status	VSI manipulation
A user accesses the port and fails 802.1X authentication because all the RADIUS servers are unreachable.	The device assigns the port to the critical microsegment. The 802.1X user and all subsequent 802.1X users on this port can access only resources in the critical microsegment.
A user in the 802.1X critical microsegment fails authentication because all the RADIUS servers are unreachable.	The port is still in the critical microsegment, and all 802.1X users on this port are in the critical microsegment.
A user in the 802.1X critical microsegment fails authentication for any reason other than unreachable servers.	The device removes the port from the 802.1X critical microsegment.

Authentication status	VSI manipulation
A user in the 802.1X critical microsegment passes 802.1X authentication.	The device removes the port from the 802.1X critical microsegment and assigns the port to the authorization microsegment. If no authorization microsegment is assigned, the device does not add the port to any microsegment.

MAC-based access control

The access device assigns or removes an 802.1X user to or from the critical microsegment on a port depending on the user's authentication status, as shown in Table 6.

Table 6 Microsegment manipulation

Authentication status	Microsegment manipulation
A user fails 802.1X authentication because all the RADIUS servers are unreachable.	The access device assigns the user to the 802.1X critical microsegment. The access device retains the user in the 802.1X critical microsegment if 802.1X reauthentication fails because none of the RADIUS servers is reachable.
A user in the 802.1X critical microsegment fails 802.1X for any reason other than server unreachable.	The access device removes the user from the 802.1X critical microsegment.
A user in the 802.1X critical microsegment passes 802.1X authentication.	The access device assigns the user to the authorization microsegment assigned by the authentication server.

ACL assignment

You can specify an authorization ACL for an 802.1X user on a remote server or the access device to control the user's access to network resources. After the user passes 802.1X authentication, the server or access device assigns the authorization ACL to the user access port. Then, the port permits or drops the matching traffic for the user depending on the rules in the ACL.

The device supports assignment of static and dynamic authorization ACLs.

- **Assignment of static authorization ACLs**—Static ACLs can be assigned by a RADIUS server or the access device. When the server or access device assigns a static ACL to a user, it assigns only the ACL number. You must manually create the ACL and configure its rules on the access device.

  To change the access permissions of a user, you can use one of the following methods:

  - Modify ACL rules in the authorization ACL on the access device.
  - Assign another ACL to the user as the authorization ACL from the RADIUS server or the access device.

  Static ACLs and their rules can be manually deleted from the access device.
- **Assignment of dynamic authorization ACLs**—Dynamic ACLs and their rules are automatically deployed by a RADIUS server, which are not configurable on the access device. Dynamic ACLs can only be named ACLs. After the device receives a server-deployed dynamic ACL and its rules, it automatically creates the ACL and configures its rules.

If the dynamic ACL assigned by the server to a user has the same name as a static ACL, the dynamic ACL cannot be issued and the user cannot come online.

A dynamic ACL and its rules are automatically deleted from the access device after all its users go offline.

Dynamic ACLs and their rules cannot be manually modified or deleted on the access device. To display information about dynamic ACLs and their rules, use the **`display dot1x connection`** or **`display acl`** command.

IMPORTANT:

The supported authorization ACLs include the following types:

- Basic ACLs, which are numbered in the range of 2000 to 2999.
- Advanced ACLs, which are numbered in the range of 3000 to 3999.
- Layer 2 ACLs, which are numbered in the range of 4000 to 4999.
- User-defined ACLs, which are numbered in the range of 5000 to 5999.

For an authorization ACL to take effect, make sure the ACL exists with rules and none of the rules contains the **`counting`**, **`established`**, **`fragment`**, **`source-mac`**, or **`logging`** keyword.

For more information about ACLs, see *ACL and QoS Command Reference*.

IMPORTANT:

If the server assigns both an authorization ACL and microsegment to an 802.1X authentication user on a microsegmented network, only the authorization microsegment takes effect.

Redirect URL assignment

The device supports the URL attribute assigned by a RADIUS server when the 802.1X-enabled port performs MAC-based access control and the port authorization state is **auto**. During authentication, the HTTP or HTTPS requests of an 802.1X user are redirected to the Web interface specified by the server-assigned URL attribute. After the user passes the Web authentication, the RADIUS server records the MAC address of the user and uses a DM (Disconnect Message) to log off the user. When the user initiates 802.1X authentication again, it will pass the authentication and come online successfully.

This feature is mutually exclusive with the EAD assistant feature.

By default, the device listens to port 6654 for HTTPS requests to be redirected. To change the redirect listening port number, see configuring HTTP redirect in *Layer 3—IP Services Configuration Guide*.

802.1X support for critical profiles

If all RADIUS servers in a RADIUS scheme are not reachable for user authentication, users will be unable to get authenticated to come online. To make sure users can access certain resources in this situation, you can specify a critical profile for them on their access port. For example, you can define critical microsegment resources in the critical profile.

For users in a VPN instance, the resources defined for that VPN instance in a critical profile take precedence over the default resources in the critical profile.

Periodic 802.1X reauthentication

Periodic 802.1X reauthentication tracks the connection status of online users and updates the authorization attributes (such as ACL and VLAN) assigned by the server.

The device reauthenticates online 802.1X users at the periodic reauthentication interval when the periodic online user reauthentication feature is enabled. The interval is controlled by a timer and the timer is user configurable. A change to the periodic reauthentication timer applies to online users only after the old timer expires and the users pass authentication.

The server-assigned session timeout timer (Session-Timeout attribute) and termination action (Termination-Action attribute) together can affect the periodic online user reauthentication feature. To display the server-assigned Session-Timeout and Termination-Action attributes, use the **`display dot1x connection`** command (see *Security Command Reference*).

- If the termination action is **Default** (logoff), periodic online user reauthentication on the device takes effect only when the periodic reauthentication timer is shorter than the session timeout timer.
- If the termination action is **Radius-request**, the periodic online user reauthentication settings on the device do not take effect. The device reauthenticates the online 802.1X users after the session timeout timer expires.

If no session timeout timer is assigned by the server, whether the device performs periodic 802.1X reauthentication depends on the periodic reauthentication configuration on the device. Support for the assignment of Session-Timeout and Termination-Action attributes depends on the server model.

With the RADIUS DAS feature enabled, the device immediately reauthenticates a user upon receiving a CoA message that carries the reauthentication attribute from a RADIUS authentication server. In this case, reauthentication will be performed regardless of whether 802.1X periodic reauthentication is enabled on the device. For more information about RADIUS DAS configuration, see "Configuring AAA."

By default, the device logs off online 802.1X users if no server is reachable for 802.1X reauthentication. The keep-online feature keeps authenticated 802.1X users online when no server is reachable for 802.1X reauthentication.

The VLANs assigned to an online user before and after reauthentication can be the same or different.

EAD assistant

Endpoint Admission Defense (EAD) is an integrated endpoint access control solution to improve the threat defensive capability of a network. The solution enables the security client, security policy server, access device, and third-party server to operate together. If a terminal device seeks to access an EAD network, it must have an EAD client, which performs 802.1X authentication.

The EAD assistant feature allows unauthenticated users to access freely accessible network segments and enables the access device to redirect the HTTP or HTTPS requests of users to a redirect URL for downloading and installing EAD clients. This feature eliminates the administrative task to deploy EAD clients.

EAD assistant is implemented by the following functionality:

- Free IP.

  A free IP is a freely accessible network segment, which has a limited set of network resources such as software and DHCP servers. To ensure security policy compliance, an unauthenticated user can access only this segment to perform operations. For example, the user can download EAD client from a software server or obtain a dynamic IP address from a DHCP server.
- Free microsegment.

A free microsegment is a freely accessible microsegment, which has a limited set of network resources such as software and DHCP servers. To ensure security policy compliance, an unauthenticated user can access only this microsegment to perform operations. For example, the user can download EAD client from a software server or obtain a dynamic IP address from a DHCP server.

- Redirect URL.

  If an unauthenticated 802.1X user is using a Web browser to access the network, EAD assistant redirects the network access requests of the user to a specific URL. For example, you can use this feature to redirect the user to the EAD client software download page.

The EAD assistant feature creates an ACL-based EAD rule automatically to open access to the free segment for each unauthenticated user.

EAD rules are implemented by using ACL resources. When the EAD rule timer expires or the user passes authentication, the rule is removed. If users fail to download EAD client or fail to pass authentication before the timer expires, they must reconnect to the network to access the free segment.

Configuring 802.1X

Restrictions and guidelines: 802.1X configuration

You can configure the port security feature to perform 802.1X. Port security combines and extends 802.1X and MAC authentication. It applies to a network (a WLAN, for example) that requires different authentication methods for different users on a port. For more information about the port security feature, see "Configuring port security."

When RADIUS DAS is enabled, an M-LAG system does not support shutting down or rebooting the access ports of 802.1X users or reauthenticating the users through CoA messages. For more information about RADIUS DAS, see "Configuring AAA."

When you configure 802.1X settings on an interface, follow these restrictions and guidelines:

- 802.1X is supported only on Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces.
- If you add a Layer 2 Ethernet interface to an aggregation group, the 802.1X settings configured on it will not take effect until it is removed from the aggregation group.
- Do not delete a Layer 2 aggregate interface if the interface has online 802.1X users.
- Do not change the link type of a port when the 802.1X guest VLAN, Auth-Fail VLAN, or critical VLAN on the port has users.
- To ensure that online 802.1X users on a Layer 2 aggregate interface with MAC-based VLAN enabled can correctly go offline, enable MAC-based VLAN also on all member ports of the aggregate interface.

On an interface, the 802.1X critical profile settings are mutually exclusive with the 802.1X critical VSI, critical VLAN, and critical microsegment settings.

On an interface, the 802.1X critical profile settings are mutually exclusive with the critical VSI, critical VLAN, and critical microsegment settings for MAC authentication.

When you configure 802.1X VLANs, VSIs, or miscrosegments, follow these restrictions and guidelines:

- If the server assigns both an authorization VSI and authorization VLAN to a user, the device uses only the authorization VLAN.
- On an interface avoid the incompatible 802.1X settings in Table 7.

Table 7 Settings incompatible with 802.1X VLANs, VSIs, or miscrosegments on a port

Settings	Incompatible settings
802.1X guest VLAN, Auth-Fail VLAN, and critical VLAN settings	802.1X guest VSI, Auth-Fail VSI, and critical VSI settings 802.1X critical microsegment settings
802.1X guest VSI, Auth-Fail VSI, and critical VSI settings	802.1X guest VLAN, Auth-Fail VLAN, and critical VLAN settings 802.1X critical microsegment settings
802.1X critical microsegment settings	802.1X guest VLAN, Auth-Fail VLAN, and critical VLAN settings 802.1X guest VSI, Auth-Fail VSI, and critical VSI settings

- On an interface, avoid the incompatible 802.1X and MAC authentication settings in Table 8.

  Table 8 MAC authentication settings incompatible with 802.1X settings on a port

Settings	Incompatible settings
802.1X guest VLAN, Auth-Fail VLAN, and critical VLAN settings	Guest VSI and critical VSI settings for MAC authentication Critical microsegment settings for MAC authentication
802.1X guest VSI, Auth-Fail VSI, and critical VSI settings	Guest VLAN and critical VLAN settings for MAC authentication Critical microsegment settings for MAC authentication

- To ensure a successful authentication, you must configure the authentication server to assign authorization microsegments, VLANs, or VSIs to the 802.1X users attached to a port in the following situations:
  - If the port is configured with the guest VLAN, Auth-Fail VLAN, or critical VLAN, you must configure VLAN authorization for the 802.1X users.
  - If the port is configured with the guest VSI, Auth-Fail VSI, or critical VSI, you must configure VSI authorization for the 802.1X users.
  - If the port is configured with critical microsegment settings, you must configure microsegment authorization for the 802.1X users.
  - If both 802.1X and MAC authentication are configured on the port, be careful with the VSI settings of the two authentication features.
    - You must configure VSI authorization for the 802.1X users if the port has a guest or critical VSI for MAC authentication.
    - Likewise, you must configure VSI authorization for the MAC authentication users if the port has an Auth-Fail, guest, or critical VSI for 802.1X authentication.
- As a best practice, do not use Web authentication in conjunction with any of the following 802.1X settings on a port:
  - Guest VLAN, Auth-Fail VLAN, and critical VLAN settings.
  - Guest VSI, Auth-Fail VSI, and critical VSI settings.
  - Critical microsegment settings.
- As a best practice, do not use port security preauthentication domain in conjunction with any of the following 802.1X settings on a port:
  - Guest VLAN, Auth-Fail VLAN, and critical VLAN settings.
  - Guest VSI, Auth-Fail VSI, and critical VSI settings.
  - Critical microsegment settings.
  - Critical profile settings.
- If you have configured multiple default authentication methods with RADIUS authentication as the primary method for an ISP domain by using the **`authentication default`** command, the following restrictions and guidelines apply:

- If users fail RADIUS authentication because all RADIUS servers are unreachable, the system tries backup authentication methods to authenticate them, without adding them to the critical VLAN, VSI, or microsegmentthe critical VLAN or VSI.
- The users will be added to the critical VLAN, VSI, or microsegment only if they fail RADIUS authentication upon unreachability of all RADIUS servers and no other authentication methods are available.

To ensure a successful HTTPS redirect for users in the following situations, make sure VLAN interfaces or VSI interfaces exist for the VLANs or VSIs that transport their packets, respectively:

- The server has assigned a redirect URL to the users.
- EAD assistant is enabled.
-

802.1X tasks at a glance

To configure 802.1X authentication, perform the following tasks:

1. Enabling 802.1X
2. Configuring basic 802.1X features
   - Enabling EAP relay or EAP termination
   - Setting the port authorization state
   - Specifying an access control method
   - (Optional.) Specifying a mandatory authentication domain on a port
   - (Optional.) Setting the 802.1X authentication timeout timers
   - (Optional.) Configuring 802.1X reauthentication
   - (Optional.) Setting the quiet timer
3. (Optional.) Configuring 802.1X VLAN assignment
   - Configuring an 802.1X guest VLAN
   - Enabling 802.1X guest VLAN assignment delay
   - Configuring an 802.1X Auth-Fail VLAN
   - Configuring an 802.1X critical VLAN
4. (Optional.) Configuring 802.1X VSI assignment
   - Configuring an 802.1X guest VSI
   - Enabling 802.1X guest VSI assignment delay
   - Configuring an 802.1X Auth-Fail VSI
   - Configuring an 802.1X critical VSI
5. (Optional.) Configuring an 802.1X critical microsegment
6. (Optional.) Specifying a critical profile for 802.1X users on a port
7. (Optional.) Configuring an 802.1X access profile
8. (Optional.) Setting the upper limit for 802.1X parameters
   - Setting the maximum number of concurrent 802.1X users on a port
   - Setting the alarm threshold and alarm clear threshold for 802.1X user access ratio
   - Setting the maximum number of authentication request attempts
   - Setting the maximum number of 802.1X authentication attempts for MAC authenticated users
9. (Optional.) Configuring other 802.1X features
   - Configuring 802.1X unauthenticated user aging

- Sending EAP-Success packets on assignment of users to the 802.1X Auth-Fail VLAN or VSI
- Sending EAP-Success packets on assignment of users to the 802.1X critical VLAN or VSI
- Enabling 802.1X online user synchronization
- Configuring the authentication trigger feature

  Perform this task when 802.1X clients cannot initiate authentication.
- Sending EAP-Success packets to 802.1X clients after successful authorization
- Discarding duplicate 802.1X EAPOL-Start requests
- Configuring online user handshake
- Configuring 802.1X offline detection
- Enabling online 802.1X users to escape from offline detection and stay online when no reachable RADIUS authentication servers are available
- Specifying supported domain name delimiters
- Removing the VLAN tags of 802.1X protocol packets sent out of a port
- Enabling 802.1X user IP freezing
- Enabling generation of dynamic IPSG binding entries for 802.1X authenticated users
- Configuring 802.1X MAC address binding
- Configuring the EAD assistant feature
- Setting the maximum size of EAP-TLS fragments sent to the server

  Use this feature to reduce the size of authentication packets sent to the server when the device uses EAP-TLS authentication method in EAP relay mode.
- Setting the unicast-trigger quiet timer
- Logging off 802.1X users
- Enabling 802.1X user logging
- Configuring SNMP notifications for 802.1X

Prerequisites for 802.1X

Before you configure 802.1X, complete the following tasks:

- Configure an ISP domain and AAA scheme (local or RADIUS authentication) for 802.1X users.
- If RADIUS authentication is used, create user accounts on the RADIUS server.
- If local authentication is used, create local user accounts on the access device and set the service type to **lan-access**.

Enabling 802.1X

Restrictions and guidelines

For 802.1X to take effect on a port, you must enable it both globally and on the port.

Procedure

1. Enter system view.

   `system-view`
2. Enable 802.1X globally.

   `dot1x`

   By default, 802.1X is disabled globally.

3. Enter interface view.
   interface *interface-type interface-number*
4. Enable 802.1X on a port.
   dot1x
   By default, 802.1X is disabled on a port.

Enabling EAP relay or EAP termination

About this task

Consider the following factors to select a proper EAP mode:

- Support of the RADIUS server for EAP packets.
- Authentication methods supported by the 802.1X client and the RADIUS server.

Restrictions and guidelines

- If EAP relay mode is used, the **user-name-format** command configured in RADIUS scheme view does not take effect. The access device sends the authentication data from the client to the server without any modification. For more information about the **user-name-format** command, see *Security Command Reference*.
- You can use both EAP termination and EAP relay in any of the following situations:
  - The client is using only MD5-Challenge EAP authentication. If EAP termination is used, you must enable CHAP authentication on the access device.
  - The client is an iNode 802.1X client and initiates only the username and password EAP authentication. If EAP termination is used, you can enable either PAP or CHAP authentication on the access device. However, for the purpose of security, you must use CHAP authentication on the access device.
- To use EAP-TLS, PEAP, or any other EAP authentication methods, you must use EAP relay. When you make your decision, see "Comparing EAP relay and EAP termination" for help.

Procedure

1. Enter system view.
   system-view
2. Configure EAP relay or EAP termination.
   dot1x authentication-method { **chap** | **eap** | **pap** }
   By default, the access device performs EAP termination and uses CHAP to communicate with the RADIUS server.

Setting the port authorization state

About this task

The port authorization state determines whether the client is granted access to the network. You can control the following authorization states of a port:

- **Authorized**—Places the port in the authorized state, enabling users on the port to access the network without authentication.
- **Unauthorized**—Places the port in the unauthorized state, denying any access requests from users on the port.
- **Auto**—Places the port initially in unauthorized state to allow only EAPOL packets to pass. After a user passes authentication, sets the port in the authorized state to allow access to the network. You can use this option in most scenarios.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the port authorization state.
   dot1x port-control { **authorized-force** | **auto** | **unauthorized-force** }
   By default, the **auto** state applies.

Specifying an access control method

About this task

The device supports port-based and MAC-based access control methods.

Restrictions and guidelines

If online 802.1X users are present on a port, changing its access control method will cause the online users to go offline.

To avoid authentication anomalies, do not execute the **dot1x port-method portbased** command on an interface that is bound to a port security authentication profile.

802.1X port-based access control is mutually exclusive with MAC authentication, Web authentication and static user authentication.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify an access control method.
   dot1x port-method { **macbased** | **portbased** }
   By default, MAC-based access control applies.

Specifying a mandatory authentication domain on a port

About this task

You can place all 802.1X users in a mandatory authentication domain for authentication, authorization, and accounting on a port. No user can use an account in any other domain to access the network through the port. The implementation of a mandatory authentication domain enhances the flexibility of 802.1X access control deployment.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify a mandatory 802.1X authentication domain on the port.

dot1x mandatory-domain *domain-name*

By default, no mandatory 802.1X authentication domain is specified.

Setting the 802.1X authentication timeout timers

About this task

The network device uses the following 802.1X authentication timeout timers:

- **Client timeout timer**—Starts when the access device sends an EAP-Request/MD5-Challenge packet to a client. If no response is received when this timer expires, the access device retransmits the request to the client.
- **Server timeout timer**—Starts when the access device sends a RADIUS Access-Request packet to the authentication server. If no response is received when this timer expires, the 802.1X authentication fails.

Restrictions and guidelines

In most cases, the default settings are sufficient. You can edit the timers, depending on the network conditions.

- In a low-speed network, increase the client timeout timer.
- In a network with authentication servers of different performance, adjust the server timeout timer.

To avoid forced logoff before the server timeout timer expires, set the server timeout timer to a value that is lower than or equal to the product of the following values:

- The maximum number of RADIUS packet transmission attempts set by using the **retry** command in RADIUS scheme view.
- The RADIUS server response timeout timer set by using the **timer response-timeout** command in RADIUS scheme view.

For information about setting the maximum number of RADIUS packet transmission attempts and the RADIUS server response timeout timer, see "Configuring AAA."

Procedure

1. Enter system view.

   system-view
2. Set the client timeout timer.

   dot1x timer supp-timeout *supp-timeout-value*

   The default is 30 seconds.
3. Set the server timeout timer.

   dot1x timer server-timeout *server-timeout-value*

   The default is 100 seconds.

Configuring 802.1X reauthentication

Restrictions and guidelines

The device selects a periodic reauthentication timer for 802.1X reauthentication in the following order:

1. Server-assigned reauthentication timer.
2. Port-specific reauthentication timer.
3. Global reauthentication timer.

4. Default reauthentication timer.

After you perform a manual reauthentication, the device reauthenticates all online 802.1X users on a port regardless of the server-assigned reauthentication attribute and the periodic reauthentication feature on the port.

Modification to the mandatory authentication domain or EAP message handling method setting does not affect the reauthentication of online 802.1X users. The modified setting takes effect only on 802.1X users that come online after the modification.

If periodic reauthentication is triggered for a user while that user is waiting for online synchronization, the system performs online synchronization and does not perform reauthentication for the user.

Procedure

1. Enter system view.

   system-view
2. Set the periodic reauthentication timer.
   - Set a global periodic reauthentication timer.

     dot1x timer reauth-period *reauth-period-value*

     The default setting is 3600 seconds.
   - Execute the following commands in sequence to set a port-specific periodic reauthentication timer:

     interface *interface-type interface-number*

     dot1x timer reauth-period *reauth-period-value*

     quit

     By default, no periodic reauthentication timer is set on a port. The port uses the global 802.1X periodic reauthentication timer.
3. Enter interface view.

   interface *interface-type interface-number*
4. Enable periodic online user reauthentication.

   dot1x re-authenticate

   By default, the feature is disabled.
5. (Optional.) Manually reauthenticate all online 802.1X users on the port.

   dot1x re-authenticate manual
6. (Optional.) Enable the keep-online feature for 802.1X users.

   dot1x re-authenticate server-unreachable keep-online

   By default, this feature is disabled. The device logs off online 802.1X users if no authentication server is reachable for 802.1X reauthentication.

   Use the keep-online feature according to the actual network condition. In a fast-recovery network, you can use the keep-online feature to prevent 802.1X users from coming online and going offline frequently.

Setting the quiet timer

About this task

The quiet timer enables the access device to wait a period of time before it can process any authentication request from a client that has failed an 802.1X authentication.

Restrictions and guidelines

You can edit the quiet timer, depending on the network conditions.

- In a vulnerable network, set the quiet timer to a high value.
- In a high-performance network with quick authentication response, set the quiet timer to a low value.

Procedure

1. Enter system view.
   `system-view`
2. Enable the quiet timer.
   `dot1x quiet-period`
   By default, the timer is disabled.
3. Set the quiet timer.
   `dot1x timer quiet-period` *`quiet-period-value`*
   The default is 60 seconds.

Configuring an 802.1X guest VLAN

Restrictions and guidelines

- You can configure only one 802.1X guest VLAN on a port. The 802.1X guest VLANs on different ports can be different.
- Assign different IDs to the port VLAN and the 802.1X guest VLAN on a port. The assignment makes sure the port can correctly process incoming VLAN-tagged traffic.
- For the 802.1X guest VLAN feature to work correctly, do not configure this feature together with EAD assistant.
- On a hybrid port, the guest VLAN can only be an untagged VLAN. If the guest VLAN is tagged, you must make it untagged, and then reconfigure it as the guest VLAN.
- When you configure multiple security features on a port, follow the guidelines in Table 9.

Table 9 Relationships of the 802.1X guest VLAN and other security features

Feature	Relationship description	Reference
802.1X Auth-Fail VLAN on a port that performs MAC-based access control	The 802.1X Auth-Fail VLAN has a higher priority than the 802.1X guest VLAN.	See "802.1X VLAN manipulation."
Port intrusion protection actions on a port that performs MAC-based access control	The 802.1X guest VLAN feature has higher priority than the block MAC action. The 802.1X guest VLAN feature has lower priority than the shutdown port action of the port intrusion protection feature.	See "Configuring port security."

Prerequisites

Before you configure an 802.1X guest VLAN, complete the following tasks:

- Create the VLAN to be specified as the 802.1X guest VLAN.
- If the 802.1X-enabled port performs MAC-based access control, perform the following operations for the port:
  - Configure the port as a hybrid port.
  - Enable MAC-based VLAN on the port. For more information about MAC-based VLANs, see *Layer 2—LAN Switching Configuration Guide*.

- If the port type is hybrid, verify that the VLAN to be specified as the guest VLAN is not in the tagged VLAN list on the port.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the 802.1X guest VLAN on the port.
   dot1x guest-vlan *guest-vlan-id*
   By default, no 802.1X guest VLAN exists on a port.

Enabling 802.1X guest VLAN assignment delay

About this task

This feature delays assigning an 802.1X-enabled port to the 802.1X guest VLAN when 802.1X authentication is triggered on the port.

This feature applies only to situations where 802.1X authentication is triggered by EAPOL-Start packets from 802.1X clients or packets from unknown MAC addresses.

To use this feature, the 802.1X-enabled port must perform MAC-based access control. To use the new MAC-triggered 802.1X guest VLAN assignment delay, you must also configure 802.1X unicast trigger on the port.

When 802.1X authentication is triggered on a port, the device performs the following operations:

1. Sends a unicast EAP-Request/Identity packet to the MAC address that triggers the authentication.
2. Retransmits the packet if no response is received within the username request timeout interval set by using the **dot1x timer tx-period** command.
3. Assigns the port to the 802.1X guest VLAN after the maximum number of request attempts set by using the **dot1x retry** command is reached.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable 802.1X guest VLAN assignment delay on the port.
   dot1x guest-vlan-delay { **eapol** | **new-mac** }
   By default, 802.1X guest VLAN assignment delay is disabled on a port.

Configuring an 802.1X Auth-Fail VLAN

Restrictions and guidelines

- Assign different IDs to the port VLAN and the 802.1X Auth-Fail VLAN on a port. The assignment makes sure the port can correctly process VLAN-tagged incoming traffic.
- You can configure only one 802.1X Auth-Fail VLAN on a port. The 802.1X Auth-Fail VLANs on different ports can be different.
- On a hybrid port, the Auth-Fail VLAN can only be an untagged VLAN.

- When you configure multiple security features on a port, follow the following guidelines:
  - On a port that performs MAC-based access control, the 802.1X Auth-Fail VLAN has a high priority over the MAC authentication guest VLAN. For more information about MAC authentication, see "Configuring MAC authentication."
  - For port intrusion protection actions on a port that performs MAC-based access control: The 802.1X Auth-Fail VLAN feature has higher priority than the block MAC action. The 802.1X Auth-Fail VLAN feature has lower priority than the shutdown port action of the port intrusion protection feature.

    For more information about port security, see "Configuring port security."

Prerequisites

Before you configure an 802.1X Auth-Fail VLAN, complete the following tasks:

- Create the VLAN to be specified as the 802.1X Auth-Fail VLAN.
- If the 802.1X-enabled port performs MAC-based access control, perform the following operations for the port:
  - Configure the port as a hybrid port.
  - Enable MAC-based VLAN on the port. For more information about MAC-based VLANs, see *Layer 2—LAN Switching Configuration Guide*.
- If the port type is hybrid, verify that the VLAN to be specified as the Auth-Fail VLAN is not in the tagged VLAN list on the port.

Procedure

1. Enter system view.

   `system-view`
2. Enter interface view.

   `interface` *`interface-type interface-number`*
3. Configure the 802.1X Auth-Fail VLAN on the port.

   `dot1x auth-fail vlan` *`authfail-vlan-id`*

   By default, no 802.1X Auth-Fail VLAN exists on a port.

Configuring an 802.1X critical VLAN

Restrictions and guidelines

- You can configure only one 802.1X critical VLAN on a port. The 802.1X critical VLANs on different ports can be different.
- Assign different IDs to the PVID and the 802.1X critical VLAN on a port. The assignment makes sure the port can correctly process VLAN-tagged incoming traffic.
- If a port configured with port-based access control is already in the 802.1X Auth-Fail VLAN, it will not move to the 802.1X critical VLAN when all authentication servers become unreachable. If all authentication servers are detected unreachable upon reauthentication initiated by a user in the Auth-Fail VLAN on a port configured with MAC-based access control, that user will remain in the Auth-Fail VLAN. The device will not move the user to the 802.1X critical VLAN.
- A port will move to the 802.1X Critical VLAN if all authentication servers are detected unreachable after it has been added to the 802.1X Guest VLAN.
- On a hybrid port, the critical VLAN can only be an untagged VLAN.

Prerequisites

Before you configure an 802.1X critical VLAN, complete the following tasks:

- Create the VLAN to be specified as a critical VLAN.

- If the 802.1X-enabled port performs MAC-based access control, perform the following operations for the port:
  - Configure the port as a hybrid port.
  - Enable MAC-based VLAN on the port. For more information about MAC-based VLANs, see *Layer 2—LAN Switching Configuration Guide*.
- If the port type is hybrid, verify that the VLAN to be specified as the critical VLAN is not in the tagged VLAN list on the port.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the 802.1X critical VLAN on the port.
   dot1x critical vlan *critical-vlan-id*
   By default, no 802.1X critical VLAN exists on a port.

Configuring an 802.1X guest VSI

Restrictions and guidelines

You can configure only one 802.1X guest VSI on a port. The 802.1X guest VSIs on different ports can be different.

For the 802.1X guest VSI feature to work correctly, do not configure this feature together with EAD assistant.

Prerequisites

To ensure that the 802.1X guest VSI on an 802.1X-enabled port can take effect, complete the following tasks:

- Enable L2VPN.
- Create the VSI to be specified as the 802.1X guest VSI, and create a VXLAN for the VSI.
- If the port performs MAC-based access control, enable MAC-based traffic match mode for dynamic Ethernet service instances on the port.

For more information, see *VXLAN Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the 802.1X guest VSI on the port.
   dot1x guest-vsi *guest-vsi-name*
   By default, no 802.1X guest VSI exists on a port.

Enabling 802.1X guest VSI assignment delay

About this task

This feature delays assigning an 802.1X-enabled port to the 802.1X guest VSI when 802.1X authentication is triggered on the port.

This feature applies only to situations where 802.1X authentication is triggered by EAPOL-Start packets from 802.1X clients or packets from unknown MAC addresses.

To use this feature, the 802.1X-enabled port must perform MAC-based access control.

When 802.1X authentication is triggered on a port, the device performs the following operations:

1. Sends a unicast EAP-Request/Identity packet to the MAC address that triggers the authentication.
2. Retransmits the packet if no response is received within the username request timeout interval set by using the **dot1x timer tx-period** command.
3. Assigns the port to the 802.1X guest VSI after the maximum number of request attempts set by using the **dot1x retry** command is reached.

This feature can work with the parallel processing of MAC authentication and 802.1X authentication feature when a port performs a combination of 802.1X and MAC authentication. The collaboration facilitates the port to perform MAC authentication before it is assigned to the 802.1X guest VSI. For information about the parallel processing of MAC authentication and 802.1X authentication feature, see "Configuring MAC authentication."

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable 802.1X guest VSI assignment delay on the port.

   dot1x guest-vsi-delay { **eapol** | **new-mac** }

   By default, 802.1X guest VSI assignment delay is disabled on a port.

Configuring an 802.1X Auth-Fail VSI

Restrictions and guidelines

You can configure only one 802.1X Auth-Fail VSI on a port. The 802.1X Auth-Fail VSIs on different ports can be different.

Prerequisites

To ensure that the 802.1X Auth-Fail VSI on an 802.1X-enabled port can take effect, complete the following tasks:

- Enable L2VPN.
- Create the VSI to be specified as the 802.1X Auth-Fail VSI, and create a VXLAN for the VSI.
- If the port performs MAC-based access control, enable MAC-based traffic match mode for dynamic Ethernet service instances on the port.

For more information, see *VXLAN Configuration Guide*.

Procedure

1. Enter system view.

system-view

2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the 802.1X Auth-Fail VSI on the port.
   dot1x auth-fail vsi *authfail-vsi-name*
   By default, no 802.1X Auth-Fail VSI exists on a port.

Configuring an 802.1X critical VSI

Restrictions and guidelines

You can configure only one 802.1X critical VSI on a port. The 802.1X critical VSIs on different ports can be different.

The 802.1X critical VSI on a port does not take effect on users already in the 802.1X Auth-Fail VSI.

Prerequisites

To ensure that the 802.1X critical VSI on an 802.1X-enabled port can take effect, complete the following tasks:

- Enable L2VPN.
- Create the VSI to be specified as the 802.1X critical VSI, and create a VXLAN for the VSI.
- If the port performs MAC-based access control, enable MAC-based traffic match mode for dynamic Ethernet service instances on the port.

For more information, see *VXLAN Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the 802.1X critical VSI on the port.
   dot1x critical vsi *critical-vsi-name*
   By default, no 802.1X critical VSI exists on a port.

Configuring an 802.1X critical microsegment

Restrictions and guidelines

You can configure only one 802.1X critical microsegment on a port. The 802.1X critical microsegments on different ports can be the same or different.

You can specify only one VSI for the critical microsegment on a port. The VSI specified for the critical microsegment does not take effect on users already in a VSI.

The critical microsegment does not take effect on a port that performs port-based access control.

For more information, see the command reference and "Restrictions and guidelines: 802.1X configuration."

Prerequisites

For the 802.1X critical microsegment you specify on a port to take effect, you must create that microsegment. For more information about microsegmentation, see "Configuring microsegmentation."

To specify a VSI fror the critical microsegment on a port, perform the following tasks:

- Enable L2VPN.
- If the port performs MAC-based access control, enable MAC-based traffic match mode for dynamic Ethernet service instances on the port.

For more information, see *VXLAN Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the 802.1X critical microsegment on the port.
   dot1x critical microsegment *microsegment-id* [**vsi** *vsi-name*]
   By default, no 802.1X critical microsegment exists on a port.

Specifying a critical profile for 802.1X users on a port

About this task

A critical profile specifies a limited set of resources accessible to 802.1X users when they cannot get authenticated because none of the applicable RADIUS servers is available.

To make sure the 802.1X users attached to a port can access the resources in a critical profile in the server unavailable situation, perform this task.

Restrictions and guidelines

You can specify only one critical profile for 802.1X authentication on a port. The critical profiles for 802.1X authentication on different ports can be different.

On an interface, the 802.1X critical profile settings are mutually exclusive with the critical VSI, critical VLAN, and critical microsegment settings.

Prerequisites

As a best practice, configure the critical profile before you perform this task. For more information about configuring critical profiles, see "Configuring AAA."

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify a critical profile for 802.1X users on the port.
   dot1x critical profile *profile-name*
   By default, no critical profile is specified for 802.1X users on a port.

Configuring an 802.1X access profile

About this task

The device uses 802.1X access profiles to manage 802.1X access settings in a unified manner. After you bind an 802.1X access profile to a port security authentication profile, the interfaces to which the port security authentication profile is applied will use the settings in the 802.1X access profile to authenticate access users.

After you bind a port security authentication profile to an interface:

- For settings that can be configured both in interface view and 802.1X access profile view (the command lines might differ in the views), the system automatically deletes the settings in interface view regardless of whether the port security authentication profile has been bound to an 802.1X access profile. To use these settings, configure them in the 802.1X access profile bound to the port security authentication profile.
- For settings that can be configured in interface view but cannot be configured in 802.1X access profile view, they can still take effect after you apply an 802.1X access profile to that interface.

For more information about port security authentication profiles, see "Configuring port security."

Restrictions and guidelines

Deleting the 802.1X access profile bound to a port security authentication profile will cause online users to go offline abnormally if the access profile has taken effect.

An 802.1X access profile can be bound to multiple port security authentication profiles, but a port security authentication profile can bind only one 802.1X access profile. To change the 802.1X access profile bound to a port security authentication profile, you must first remove the original binding.

Procedure

1. Enter system view.

   system-view
2. Create an 802.1X access profile and enter its view.

   dot1x access-profile name *profile-name*

   By default, no 802.1X access profiles exist.
3. Configure 802.1X features in the 802.1X access profile.

   For information about the features that can be configured in an 802.1X access profile, see 802.1X commands in the command reference.
4. Enter port security authentication profile view.

   port-security authentication-profile name *profile-name*
5. Bind the 802.1X access profile to the port security authentication profile.

   dot1x access-profile *profile-name*

   By default, no 802.1X access profile is bound to a port security authentication profile.

Configuring 802.1X unauthenticated user aging

About this task

802.1X unauthenticated user aging applies to users added to the following access control segments because they have not been authenticated or have failed authentication:

- 802.1X guest, Auth-Fail, or critical VLANs.
- 802.1X guest, Auth-Fail, or critical VSIs.
- 802.1X critical microsegments.

When a user in one of those access control segments ages out, the device removes the user from the segment and deletes the MAC address entry for the user from the access port.

For users in one of those segments on one port to be authenticated successfully and come online on another port, enable this feature. In any other scenarios, disable this feature as a best practice.

The 802.1X user aging mechanism on a port depends on its access control mode.

- If the port uses port-based access control, an 802.1X unauthenticated user aging timer starts when the port is assigned to one of the following access control segments:
  - Critical microsegment.
  - Auth-Fail VLAN or VSI.
  - Critical VLAN or VSI.

  When the aging timer expires, the port is removed from the segment and all MAC address entries for users in the segment are also removed.
- If the port uses MAC-based access control, an 802.1X unauthenticated user aging timer starts for each 802.1X user when they are assigned to one of the following access control segments:
  - Auth-Fail VLAN or VSI.
  - Critical VLAN or VSI.
  - Guest VLAN or VSI.

  When the aging timer for a user expires, the device removes that user from the segment.

The removed users will be unable to access any network resources until after another authentication is triggered.

Restrictions and guidelines

As a best practice, use this feature on a port only if you want to have its unauthenticated users to be authenticated and come online on a different port.

Procedure

1. Enter system view.

   system-view
2. Set the user aging timer for a type of 802.1X microsegment, VLAN, or VSI.

   dot1x timer user-aging { **auth-fail-vlan** | **auth-fail-vsi** | **critical-microsegment** | **critical-vlan** | **critical-vsi** | **guest-vlan** | **guest-vsi** } *aging-time-value*

   By default, the user aging timers for all applicable types of 802.1X microsegments, VLANs, and VSIs are 1000 seconds.
3. Enter interface view.

   interface *interface-type interface-number*
4. Enable 802.1X unauthenticated user aging.

   dot1x unauthenticated-user aging enable

   By default, 802.1X unauthenticated user aging is enabled.

Sending EAP-Success packets on assignment of users to the 802.1X Auth-Fail VLAN or VSI

About this task

By default, the device sends EAP-Failure packets to 802.1X clients when the client users are assigned to the 802.1X Auth-Fail VLAN or VSI on a port. However, some 802.1X clients cannot send DHCP requests for IP addresses after they receive EAP-Failure packets.

To have these clients obtain IP addresses and access resources after they are assigned to the 802.1X Auth-Fail VLAN or VSI, perform this task.

This task enables the device to send EAP-Success packets instead of EAP-Failure packets to 802.1X clients when the client users are assigned to the 802.1X Auth-Fail VLAN or VSI on the port.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the device to send an EAP-Success packet to a client when the client user is assigned to the 802.1X Auth-Fail VLAN or VSI on the port.

   dot1x auth-fail eapol

   By default, the device sends an EAP-Failure packet to a client when the client user is assigned to the 802.1X Auth-Fail VLAN or VSI.

Sending EAP-Success packets on assignment of users to the 802.1X critical VLAN or VSI

About this task

By default, the device sends EAP-Failure packets to 802.1X clients when the client users are assigned to the 802.1X critical VLAN or VSI. Some 802.1X clients cannot respond to the EAP-Request/Identity packet from the device for reauthentication if they have received an EAP-Failure packet. As a result, reauthentication for these clients will fail after the authentication server becomes reachable.

To avoid this situation, enable the device to send EAP-Success packets instead of EAP-Failure packets to 802.1X clients when the client users are assigned to the 802.1X critical VLAN or VSI.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the device to send an EAP-Success packet to an 802.1X client when its client user is assigned to the critical VLAN or VSI on the port.

   dot1x critical eapol

   By default, the device sends an EAP-Failure packet to an 802.1X client when its client user is assigned to the critical VLAN or VSI.

Enabling 802.1X online user synchronization

About this task

IMPORTANT:

This feature takes effect only when the device uses an IMC RADIUS server to authenticate 802.1X users.

To ensure that the RADIUS server maintains the same online 802.1X user information as the device after the server state changes from unreachable to reachable, use this feature.

This feature synchronizes online 802.1X user information between the device and the RADIUS server when the RADIUS server state is detected having changed from unreachable to reachable.

When synchronizing online 802.1X user information on a port with the RADIUS server, the device initiates 802.1X authentication in turn for each authenticated online 802.1X user to the RADIUS server.

If synchronization fails for an online user, the device logs off that user unless the failure occurs because the server has become unreachable again.

Restrictions and guidelines

The amount of time required to complete online user synchronization increases as the number of online users grows. This might result in an increased delay for new 802.1X users and users in the critical VLAN or VSI to authenticate or reauthenticate to the RADIUS server and come online.

To have this feature take effect, you must use it in conjunction with the RADIUS server status detection feature, which is configurable with the **radius-server test-profile** command. When you configure this feature, make sure the detection interval is shorter than the RADIUS server quiet timer configured by using the **timer quiet** command in RADIUS scheme view. The server state changes to active on expiration of the quiet timer regardless of its actual reachability. Setting a shorter detection interval than the quiet timer prevents the RADIUS server status detection feature from falsely reporting the server reachability.

For more information about the RADIUS server status detection feature, see "Configuring AAA."

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable 802.1X online user synchronization.

   dot1x server-recovery online-user-sync

   By default, 802.1X online user synchronization is disabled.

Configuring the authentication trigger feature

About this task

The authentication trigger feature enables the access device to initiate 802.1X authentication when 802.1X clients cannot initiate authentication.

This feature provides the multicast trigger and unicast trigger (see 802.1X authentication initiation in "802.1X overview").

Restrictions and guidelines

- Enable the multicast trigger on a port when the clients attached to the port cannot send EAPOL-Start packets to initiate 802.1X authentication.
- As a best practice to conserve link bandwidth, disable the multicast trigger if a lot of VLANs are configured on the port.
- Enable the unicast trigger on a port if only a few 802.1X clients are attached to the port and these clients cannot initiate authentication.
- To avoid duplicate authentication packets, do not enable both triggers on a port.

- As a best practice, do not use the unicast trigger on a port that performs port-based access control. If you do so, users on the port might fail to come online.

Procedure

1. Enter system view.
   system-view
2. (Optional.) Set the username request timeout timer.
   dot1x timer tx-period *tx-period-value*
   The default is 30 seconds.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable an authentication trigger.
   dot1x { **multicast-trigger** | **unicast-trigger** }
   By default, the multicast trigger is enabled and the unicast trigger is disabled.

Setting the maximum number of concurrent 802.1X users on a port

About this task

Perform this task to prevent the system resources from being overused.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the maximum number of concurrent 802.1X users on a port.
   dot1x max-user [**preauth-domain** | **auth-fail-domain**] *max-number*
   The default is 4294967295.

Setting the alarm threshold and alarm clear threshold for 802.1X user access ratio

About this task

The 802.1X user access ratio on an interface is the percentage of current online 802.1X users to the maximum number of concurrent 802.1X users on the interface (configured by using the **dot1x max-user** command).

After you use the **snmp-agent trap enable dot1x** command to enable SNMP notifications for 802.1X user access ratio and use the **dot1x max-user-alarm** command to set the alarm threshold and alarm clear threshold:

- If the percentage of 802.1X user access ratio on an interface reaches the specified alarm threshold for the first time, or increases to the alarm threshold from a value below or equal to the alarm clear threshold, the device sends an alarm notification.
- If the percentage of 802.1X user access ratio on the interface drops to the alarm clear threshold from a value above or equal to the alarm threshold, the device sends an alarm clear notification.

If the user access ratio on an interface has reached or exceeded the alarm threshold before SNMP notifications is enabled, the alarm is triggered in the following conditions after SNMP notifications is enabled:

- A user comes online and the alarm threshold is exceeded.
- A user goes offline and the alarm threshold is reached or exceeded.

Procedure

1. Enter system view.

   system-view

2. Set the alarm threshold and alarm clear threshold for 802.1X user access ratio in percentage.

   dot1x max-user-alarm trigger-threshold *trigger-threshold* **clear-threshold** *clear-threshold*

   By default, the alarm threshold and alarm clear threshold for 802.1X user access ratio in percentage is 100 and 50, respectively.

Setting the maximum number of authentication request attempts

About this task

The access device retransmits an authentication request if it does not receive any responses to the request from the client within a period of time. To set the time, use the **dot1x timer tx-period** *tx-period-value* command or the **dot1x timer supp-timeout** *supp-timeout-value* command. The access device stops retransmitting the request if it has made the maximum number of request transmission attempts but still receives no response.

Procedure

1. Enter system view.

   system-view

2. Set the maximum number of attempts for sending an authentication request.

   dot1x retry *retries*

   The default setting is 2.

Sending EAP-Success packets to 802.1X clients after successful authorization

About this task

By default, the device sends an EAP-Success packet to a client after it receives a RADIUS Access-Accept packet sent by the RADIUS server for the user of that client. After that, the device grants the user access to the network through the user's access port. Upon receiving the EAP-Success packet, the client immediately initiates a DHCP request to obtain an IP address. However, if the device has not yet received authorization information assigned by the RADIUS server, the client directly obtains an IP address from its access network segment. If its access network segment is different from its authorization network segment after the RADIUS server assigns the authorization information, the client will be unable to come online.

To ensure that each 802.1X client obtains an IP address from the authorization network segment, use this feature to configure the device to send EAP-Success packets to 802.1X clients after authorization for the users of the clients succeeds.

Restrictions and guidelines

When this feature is configured, authentication for some users might fail due to untimely authorization if the RADIUS server or device needs to process a large number of authentication processes, resulting in authentication response timeout. As a best practice, use this feature based on the service processing capabilities of the device and the RADIUS server in the actual application scenario.

Procedure

1. Enter system view.

   system-view

2. Configure the device to send EAP-Success packets to 802.1X clients after authorization for the users of the clients succeeds.

   dot1x eap-success post-authorization

   By default, the device sends EAP-Success packets to 802.1X clients immediately after authentication for the users of the clients succeeds.

Discarding duplicate 802.1X EAPOL-Start requests

About this task

During 802.1X authentication, the device might receive duplicate EAPOL-Start requests from an 802.1X user. By default, the device delivers the duplicate EAPOL-Start requests to the authentication server as long as they are legal. However, this mechanism might result in authentication failure if the authentication server cannot respond to duplicate EAPOL-Start requests. To resolve this issue, perform this task on the user access interface to discard duplicate EAPOL-Start requests.

Restrictions and guidelines

As a best practice, perform this task only if the server cannot respond to duplicate EAPOL-Start requests. Do not perform this task in other situations.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Discard duplicate EAPOL-Start requests on the interface.

   dot1x duplicate-eapol-start discard

   By default, the device does not discard duplicate EAPOL-Start requests on an interface if the requests are legal.

Configuring online user handshake

About this task

The online user handshake feature checks the connectivity status of online 802.1X users. The access device sends handshake requests (EAP-Request/Identity) to online users at the interval specified by the **dot1x timer handshake-period** command. If the device does not receive any EAP-Response/Identity packets from an online user after it has made the maximum handshake

attempts, the device sets the user to offline state. To set the maximum handshake attempts, use the **dot1x retry** command.

Typically, the device does not reply to 802.1X clients' EAP-Response/Identity packets with EAP-Success packets. Some 802.1X clients will go offline if they do not receive the EAP-Success packets for handshake. To avoid this issue, enable the online user handshake reply feature.

If iNode clients are deployed, you can also enable the online user handshake security feature to check authentication information in the handshake packets from clients. This feature can prevent 802.1X users that use illegal client software from bypassing iNode security check, such as dual network interface cards (NICs) detection. If a user fails the handshake security checking, the device sets the user to the offline state.

Restrictions and guidelines

- If the network has 802.1X clients that cannot exchange handshake packets with the access device, disable the online user handshake feature. This operation prevents the 802.1X connections from being incorrectly torn down.
- To use the online user handshake security feature, make sure the online user handshake feature is enabled.
- The online user handshake security feature takes effect only on the network where the iNode client and IMC server are used.
- Enable the online user handshake reply feature only if 802.1X clients will go offline without receiving EAP-Success packets from the device.
- To ensure online user handshake and new user authentication when a large number of users are present, set the following parameters to a large value:
  - Handshake timer (set by using the **dot1x timer handshake-period** command).
  - Maximum number of attempts to send an authentication request to a client (set by using the **dot1x retry** command).

Procedure

1. Enter system view.

   system-view

2. (Optional.) Set the handshake timer.

   dot1x timer handshake-period *handshake-period-value*

   The default is 15 seconds.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable the online user handshake feature.

   dot1x handshake

   By default, the feature is enabled.

5. (Optional.) Enable the online user handshake security feature.

   dot1x handshake secure

   By default, the feature is disabled.

6. (Optional.) Enable the 802.1X online user handshake reply feature.

   dot1x handshake reply enable

   By default, the device does not reply to 802.1X clients' EAP-Response/Identity packets during the online handshake process.

Configuring 802.1X offline detection

About this task

The 802.1X offline detection feature monitors the online status of 802.1X users. This feature uses an offline detection timer to set the interval that the device must wait for traffic from a user before the device determines that the user is idle. If the device has not received traffic from a user before the timer expires, the device logs off that user and requests the accounting server to stop accounting for the user.

The traffic monitored by this feature includes 802.1X protocol packets sent from 802.1X clients.

This feature takes effect on both of the following types of users:

- Users in preauthentication domains, authentication domains, critical domains, and Auth-Fail domains.
- Users assigned to guest VLANs or VSIs, Auth-Fail VLANs or VSIs, and critical VLANs, VSIs, or microsegments.

Restrictions and guidelines

The 802.1X offline detection feature takes effect only on a port that performs MAC-based access control. If you change the port access mode to port-based, the 802.1X offline detection feature cannot take effect.

If you enable 802.1X offline detection on a Layer 2 aggregate interface, delay exists for the device to log off an idle user.

For this feature to operate as expected, do not set the offline detection timer to the same value as either of the following timers:

- Handshake timer (set by using the **dot1x timer handshake-period** command).
- Periodic reauthentication timer (set by using the **dot1x timer reauth-period** command).

Procedure

1. Enter system view.
   system-view
2. Set the 802.1X offline detection timer.
   dot1x timer offline-detect *offline-detect-value*
   By default, the 802.1X offline detection timer is 300 seconds.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable 802.1X offline detection.
   dot1x offline-detect enable
   By default, 802.1X offline detection is disabled.

Enabling online 802.1X users to escape from offline detection and stay online when no reachable RADIUS authentication servers are available

About this task

The 802.1X offline detection feature logs off an online 802.1X user if it has not detected traffic from that user before the offline-detect timer expires. To prevent online 802.1X users on a port from being forced offline by the 802.1X offline detection feature and stay online when none of the RADIUS servers in their ISP domain is reachable, perform this task.

Restrictions and guidelines

Use this feature only when RADIUS scheme authentication is configured for the 802.1X users on a port. If local or no authentication is also configured, offline detection might be undesirably disabled for the 802.1X users when they come online through local authentication or without authentication.

Procedure

1. Enter system view.

   `system-view`

2. Enter interface view.

   `interface` *`interface-type interface-number`*

3. Enable online 802.1X users to escape from 802.1X offline detection and stay online when no reachable RADIUS authentication servers are available.

   `dot1x auth-server-unavailable escape`

   By default, online 802.1X users cannot escape from 802.1X offline detection (if enabled) when no reachable RADIUS authentication servers are available.

Specifying supported domain name delimiters

About this task

By default, the access device supports the at sign (@) as the delimiter. You can also configure the access device to accommodate 802.1X users that use other domain name delimiters. The configurable delimiters include the at sign (@), backslash (\), dot (.), and forward slash (/). Usernames that include domain names can use the format of *username***@***domain-name*, *domain-name******username*, *username***.***domain-name*, or *username***/***domain-name*.

If an 802.1X username string contains multiple configured delimiters, the rightmost delimiter is the domain name delimiter. For example, if you configure the backslash (\), dot (.), and forward slash (/) as delimiters, the domain name delimiter for the username string 121.123/22\@abc is the backslash (\). The username is @**abc** and the domain name is **121.123/22**.

Restrictions and guidelines

If a username string contains none of the delimiters, the access device authenticates the user in the mandatory or default ISP domain.

If you configure the access device to send usernames with domain names to the RADIUS server, make sure the domain delimiter can be recognized by the RADIUS server. For username format configuration, see the **`user-name-format`** command in *Security Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Specify a set of domain name delimiters for 802.1X users.

   dot1x domain-delimiter *string*

   By default, only the at sign (@) delimiter is supported.

Removing the VLAN tags of 802.1X protocol packets sent out of a port

About this task

This feature operates on a hybrid port to have it send 802.1X protocol packets with their VLAN tags removed, regardless of whether the port is a tagged or untagged member of a VLAN.

Use this feature if the 802.1X-enabled hybrid port is a tagged member of its PVID and the attached 802.1X clients cannot recognize VLAN-tagged 802.1X protocol packets.

Restrictions and guidelines

This feature removes the VLAN tags of all 802.1X protocol packets sent out of the port to 802.1X clients. Do not use this feature if VLAN-aware 802.1X clients are attached to the port. As a best practice, perform this task only in the described applicable scenario.

Prerequisites

Set the link type of the 802.1X-enabled port to hybrid. For more information, see VLAN configuration in *Layer 2 LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Remove the VLAN tags of all 802.1X protocol packets sent out of the port to 802.1X clients.

   dot1x eapol untag

   By default, whether the device removes the VLAN tags of all 802.1X protocol packets sent out of a port to 802.1X clients depends on the configuration in the VLAN module.

CAUTION:

This command removes the VLAN tags of all 802.1X protocol packets sent out of the port to 802.1X clients. Do not use this command if VLAN-aware 802.1X clients are attached to the port. As a best practice, use this command only in the described applicable scenario.

Setting the maximum number of 802.1X authentication attempts for MAC authenticated users

About this task

When a port uses both 802.1X authentication and MAC authentication, the device accepts 802.1X authentication requests from MAC authenticated users. If a MAC authenticated user passes 802.1X authentication, the user will come online as an 802.1X user. If the user fails 802.1X authentication, the user continues to make 802.1X authentication attempts depending on client configuration.

Perform this task to limit the number of 802.1X authentication attempts made by a MAC authenticated user.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Set the maximum number of 802.1X authentication attempts for MAC authenticated users on the port.

   dot1x after-mac-auth max-attempt *max-attempts*

   By default, the number of 802.1X authentication attempts for MAC authenticated users is not limited on a port.

Enabling 802.1X user IP freezing

About this task

This feature works with the IP source guard feature. 802.1X-based IP source guard requires that 802.1X clients support sending user IP addresses to the access device. The device uses information such as user MAC addresses and IP addresses obtained through 802.1X to generate IPSG bindings to filter out IPv4 packets from unauthenticated 802.1X users. For information about IP source guard, see "Configuring IP source guard."

This feature prevents any authenticated 802.1X users on a port from changing their IP addresses. After you enable this feature, the port does not update the IP addresses in dynamic IPSG bindings for 802.1X users. If an 802.1X user uses an IP address different from the IP address in its IPSG binding entry, the port denies the user access.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable 802.1X user IP freezing.

   dot1x user-ip freeze

   By default, 802.1X user IP freezing is disabled.

Enabling generation of dynamic IPSG binding entries for 802.1X authenticated users

About this task

IMPORTANT:

This feature must operate in conjunction with the IP source guard (IPSG) feature.

By default, the device generates a dynamic IPv4SG or IPv6SG binding entry for an 802.1X authenticated user after the user obtains a static or DHCP assigned IP address.

To allow only 802.1X users with DHCP assigned IP addresses to access the network, perform the following operations:

- Enable IPSG.
- Disable generation of dynamic IPv4SG or IPv6SG binding entries for 802.1X authenticated users.
- Enable DHCP snooping. The device will generate IPv4SG or IPv6SG binding entries for the users based on DHCP snooping.

For more information about IPSG, see IP source guard in *Security Configuration Guide*.

Restrictions and guidelines

This feature takes effect only on 802.1X users that come online after the feature is enabled. If the IP address of an online 802.1X user changes, the device will update the dynamic IPv4SG or IPv6SG binding entry for the user.

Disabling this feature does not delete the existing dynamic IPv4SG or IPv6SG binding entries for online 802.1X users. If the IP address of an online 802.1X user changes after the feature is disabled, the device will delete the dynamic IPv4SG or IPv6SG binding entry for the user.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable generation of dynamic IPv4SG or IPv6SG binding entries for 802.1X authenticated users.

   dot1x { **ip-verify-source** | **ipv6-verify-source** } **enable**

   By default, generation of dynamic IPv4SG or IPv6SG binding entries for 802.1X authenticated users is enabled.

Configuring 802.1X MAC address binding

About this task

This feature can automatically bind MAC addresses of authenticated 802.1X users to the users' access port and generate 802.1X MAC address binding entries. You can also use the **dot1x mac-binding** *mac-address* command to manually add 802.1X MAC address binding entries.

802.1X MAC address binding entries never age out. They can survive a user logoff or a device reboot. If users in the 802.1X MAC address binding entries perform 802.1X authentication on another port, they cannot pass authentication.

Restrictions and guidelines

The 802.1X MAC address binding feature takes effect only when the port performs MAC-based access control.

To delete an 802.1X MAC address binding entry, use the **undo dot1x mac-binding** *mac-address* command. An 802.1X MAC address binding entry cannot be deleted when the user in the entry is online.

After the number of 802.1X MAC address binding entries reaches the upper limit of concurrent 802.1X users (set by using the **dot1x max-user** command), the following restrictions exist:

- Users not in the binding entries will fail authentication even after users in the binding entries go offline.
- New 802.1X MAC address binding entries are not allowed.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the 802.1X MAC address binding feature.
   dot1x mac-binding enable
   By default, the feature is disabled.
4. (Optional.) Manually add an 802.1X MAC address binding entry.
   dot1x mac-binding *mac-address*
   By default, no 802.1X MAC address binding entries exist on a port.

Configuring the EAD assistant feature

Restrictions and guidelines

- If you enable EAD assistant in conjunction with port security, EAD assistant cannot take effect on ports operating in autoLearn port security mode.
- To make the EAD assistant feature take effect on an 802.1X-enabled port, you must set the port authorization mode to **auto**.
- When port security is enabled, the free IPs cannot take effect.
- EAD assistant might cause malfunction of 802.1X Auth-Fail VLANs or VSIs and critical VLANs or VSIs. To ensure that users can correctly access Auth-Fail VLANs or VSIs and critical VLANs or VSIs, use the **dot1x ead-assistant permit authentication-escape** command.
- The **dot1x ead-assistant permit authentication-escape** command cannot take effect on ports in port-based access control.
- If you use free IP and Auth-Fail VLAN features together, make sure the resources in the Auth-Fail VLAN are on the free IP segments.
- The server that provides the redirect URL must be on the free IP accessible to unauthenticated users.
- If you configure both EAD assistant and 802.1X unicast trigger on a port that performs port-based access control, 802.1X unicast trigger cannot take effect.

When you use both EAD assistant and MAC authentication on the device, follow these restrictions and guidelines:

- If both EAD assistant and MAC authentication are configured, the device does not mark the MAC address of a user that has failed MAC authentication as a silent MAC address. If the user

has never passed MAC authentication, packets from the user can trigger MAC authentication again only after the user's EAD entry ages out.

- As a best practice, do not configure MAC authentication guest VSIs, guest VLANs, critical VSIs, or critical VLANs. The VLANs or VSIs might fail to work correctly when both EAD assistant and MAC authentication are configured on the device.
- As a best practice, do not configure the Web authentication or IP source guard feature. These features might fail to work correctly when both EAD assistant and MAC authentication are configured on the device.
- If the MAC address of a user has been marked as a silent MAC address before you enable EAD assistant, packets from the user can trigger 802.1X or MAC authentication only after the quiet timer expires.

Procedure

1. Enter system view.

   system-view

2. Enable the EAD assistant feature.

   dot1x ead-assistant enable

   By default, this feature is disabled.

3. Configure a free IP.

   dot1x ead-assistant free-ip *ip-address* { *mask-length* | *mask-address* }

   Repeat this command to configure multiple free IPs.

4. Configure a free microsegment.

   dot1x ead-assistant free-microsegment *free-microsegment-id*

   Repeat this command to configure a maximum of 20 free microsegments.

5. (Optional.) Configure the redirect URL if users will use Web browsers to access the network.

   dot1x ead-assistant url *url-string* [**secondary**] [**track** *track-entry-number*]

   By default, no redirect URL exists.

   By default, the device listens to port 6654 for HTTPS requests to be redirected. To change the redirect listening port number, see configuring HTTP redirect in *Layer 3—IP Services Configuration Guide*.

6. (Optional.) Set the EAD rule timer.

   dot1x timer ead-timeout *ead-timeout-value*

   The default setting is 30 minutes.

   To avoid using up ACL resources when a large number of EAD users exist, you can shorten the EAD rule timer.

7. (Optional.) Enable support for correctly using Auth-Fail VLANs or VSIs and critical VLANs or VSIs when 802.1X EAD assistant is enabled.

   dot1x ead-assistant permit authentication-escape

   By default, 802.1X Auth-Fail VLANs or VSIs and critical VLANs or VSIs cannot function correctly when 802.1X EAD assistant is enabled.

Setting the maximum size of EAP-TLS fragments sent to the server

About this task

When the device uses EAP-TLS authentication method in EAP relay mode, the RADIUS packets might exceed the maximum packet size supported by the RADIUS server. This situation typically occurs when long EAP-TLS messages are encapsulated in the EAP-Message attribute of the RADIUS packet sent to the RADIUS server.

To avoid authentication failures caused by oversized packets, fragment the EAP-TLS messages depending on the maximum RADIUS packet size supported by the remote RADIUS server.

For example, the maximum packet length allowed by the server is 1200 bytes and the length of a RADIUS packet (excluding the EAP-Message attribute) is 800 bytes. To make sure the maximum length of a RADIUS packet does not exceed 1200 bytes, you must set the maximum length of an EAP-TLS fragment to a value less than 400 bytes.

Restrictions and guidelines

802.1X EAP-TLS fragmentation takes effect only when EAP relay mode is used. For more information about enabling EAP relay, see "Enabling EAP relay or EAP termination."

Procedure

1. Enter system view.

   system-view
2. Enable 802.1X EAP-TLS fragmentation and set the maximum EAP-TLS fragment size.

   dot1x eap-tls-fragment to-server *eap-tls-max-length*

   By default, EAP-TLS messages are not fragmented.

Setting the unicast-trigger quiet timer

About this task

To suppress the unicast trigger from requesting an unknown source MAC address for 802.1X authentication after it has made the maximum number of failed attempts, perform this task.

The 802.1X unicast-trigger quiet timer sets the duration that the unicast trigger is suppressed from sending EAP-Request/Identity requests to an unknown MAC address. This timer starts when the device fails to receive a response from an unknown MAC address after the number of unicast EAP-Request/Identity requests sent to that MAC address has reached the limit. The limit is configurable with the **dot1x retry** command.

Restrictions and guidelines

The network access delay introduced by the unicast-trigger quiet timer increases as the timer value increases. When you set the unicast-trigger quiet timer, make sure its value does not introduce undesired delay for 802.1X authentication users to come online.

You cannot use the unicast-trigger quiet timer in conjunction with the guest VLAN, guest VSI, and EAD assistant feature.

Procedure

1. Enter system view.

   system-view
2. Set the unicast-trigger quiet timer.

   dot1x timer unicast-trigger quiet-period *quiet-period-value*

By default, the unicast-trigger timer is set to 0 seconds, which indicates that the unicast-trigger timer is not enabled.

Logging off 802.1X users

About this task

Perform this task to log off specified 802.1X users and clear information about these users from the device. These users must perform 802.1X authentication to come online again.

Procedure

To log off 802.1X users, execute the following command in user view:

reset dot1x access-user [**interface** *interface-type interface-number* | **mac** *mac-address* | **microsegment** *microsegment-id* | **online-type** { **auth-fail-domain** | **critical-domain** | **preauth-domain** | **success** } | **username** *username* | **vlan** *vlan-id* | **vsi** *vsi-name*]

Enabling 802.1X user logging

About this task

This feature enables the device to generate logs about 802.1X users and send the logs to the information center. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

To prevent excessive 802.1X user log entries, use this feature only if you need to analyze abnormal 802.1X user logins or logouts.

Procedure

1. Enter system view.

   system-view

2. Enable 802.1X user logging.

   dot1x access-user log enable [**abnormal-logoff** | **failed-login** | **ip-change** | **maxnum-clear-threshold** | **maxnum-trigger-threshold** | **normal-logoff** | **successful-login**] *

   By default, 802.1X user logging is disabled.

   If you do not specify any parameters, this command enables all types of 802.1X user logs.

Configuring SNMP notifications for 802.1X

About this task

This feature enables generating SNMP notifications for the following 802.1X events:

- If you specify the **dot1x-not-support** keyword, the system generates a notification when an interface does not support 802.1X.
- If you specify the **resource-not-enough** keyword, the system generates a notification when ACL resources become insufficient.
- If you specify the **unicast-not-support** keyword, the system generates a notification when an interface does not support unicast trigger.

- If you specify the **user-maxnum** keyword, the system generates a notification for a 802.1X user access ratio event.

After you enable SNMP notifications for 802.1X, the 802.1X module notifies the NMS of important module events. The notifications are sent to the device's SNMP module. For the notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP notifications, see *Network Management and Monitoring Configuration Guide*.

After you configure this feature to enable SNMP notifications for 802.1X user access ratio and use the **dot1x max-user-alarm** command to set the alarm threshold and alarm clear threshold:

- If the percentage of 802.1X user access ratio on an interface reaches the specified alarm threshold for the first time, or increases to the alarm threshold from a value below or equal to the alarm clear threshold, the device sends an alarm notification.
- If the percentage of 802.1X user access ratio on the interface drops to the alarm clear threshold from a value above or equal to the alarm threshold, the device sends an alarm clear notification.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for 802.1X.

   snmp-agent trap enable dot1x [**dot1x-not-support** | **resource-not-enough** | **unicast-not-support** | **user-maxnum**] *

   By default, SNMP notifications for 802.1X are disabled.

Display and maintenance commands for 802.1X

Execute **display** commands in any view and **reset** commands in user view.

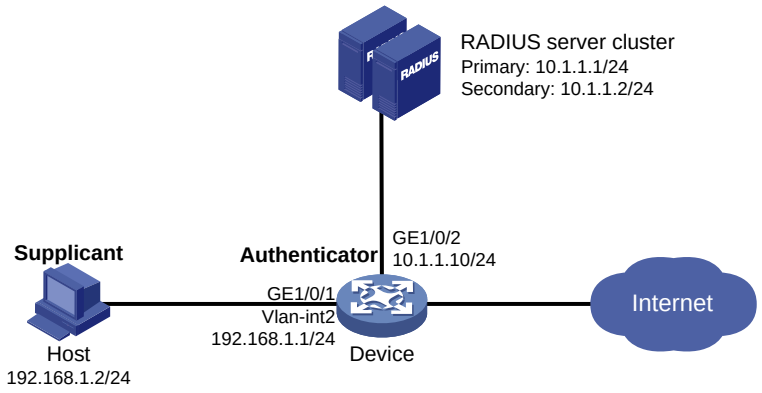
Task	Command
Display 802.1X session information, statistics, or configuration information of specified or all ports.	**display dot1x** [**sessions** | **statistics**] [**interface** *interface-type interface-number*]
Display information about 802.1X access profiles.	**display dot1x access-profile** [**name** *profile-name*]
Display online 802.1X user information.	**display dot1x connection** [**open**] [[**m-lag** [**local** | **peer**]] [**interface** *interface-type interface-number* | **online-type** { **auth-fail-domain** | **critical-domain** | **preauth-domain** | **success** } | **slot** *slot-number* | **user-name** *name-string*] | **user-mac** *mac-address*]
Display the MAC addresses of 802.1X users in a type of 802.1X microsegment, VLAN, or VSI.	**display dot1x mac-address** { **auth-fail-vlan** | **auth-fail-vsi** | **critical-microsegment** | **critical-vlan** | **critical-vsi** | **guest-vlan** | **guest-vsi** } [**interface** *interface-type interface-number*]
Display unknown source MAC addresses in the unicast-trigger quiet period.	**display dot1x unicast-trigger quiet-mac** [**interface** *interface-type interface-number*]
Remove users from the 802.1X guest VLAN on a port.	**reset dot1x guest-vlan interface** *interface-type interface-number*

Task	Command
	[**mac-address** *mac-address*]
Remove users from the 802.1X guest VSI on a port.	**reset dot1x guest-vsi interface** *interface-type interface-number* [**mac-address** *mac-address*]
Clear 802.1X statistics.	**reset dot1x statistics** [**interface** *interface-type interface-number*]
Remove the records of unknown source MAC addresses in the unicast-trigger quiet period.	**reset dot1x unicast-trigger quiet-mac** [**interface** *interface-type interface-number* | **mac-address** *mac-address*]

802.1X authentication configuration examples

Example: Configuring basic 802.1X authentication

Network configuration



As shown in Figure 12, the access device performs 802.1X authentication for users that connect to GigabitEthernet 1/0/1. Implement MAC-based access control on the port, so the logoff of one user does not affect other online 802.1X users.

Use RADIUS servers to perform authentication, authorization, and accounting for the 802.1X users. If RADIUS authentication fails, perform local authentication on the access device.

Configure the RADIUS server at 10.1.1.1/24 as the primary authentication and accounting server, and the RADIUS server at 10.1.1.2/24 as the secondary authentication and accounting server. Assign all users to ISP domain **bbb**.

Set the shared key to **name** for packets between the access device and the authentication server. Set the shared key to **money** for packets between the access device and the accounting server.

Figure 12 Network diagram

Procedure

For information about the RADIUS commands used on the access device in this example, see *Security Command Reference*.

1. Configure the RADIUS servers and add user accounts for the 802.1X users. Make sure the RADIUS servers can provide authentication, authorization, and accounting services. (Details not shown.)

2. Assign an IP address to each interface. (Details not shown.)
3. Configure user accounts for the 802.1X users on the access device:

   # Add a local network access user with username **localuser** and password **123456TESTplat&!** in plaintext. (Make sure the username and password are the same as those configured on the RADIUS servers.)

   ```
   <Device> system-view
   [Device] local-user localuser class network
   [Device-luser-network-localuser] password simple 123456TESTplat&!
   ```

   # Set the service type to **lan-access**.

   ```
   [Device-luser-network-localuser] service-type lan-access
   [Device-luser-network-localuser] quit
   ```

4. Configure a RADIUS scheme on the access device:

   # Create a RADIUS scheme named **radius1** and enter RADIUS scheme view.

   ```
   [Device] radius scheme radius1
   ```

   # Specify the IP addresses of the primary authentication and accounting RADIUS servers.

   ```
   [Device-radius-radius1] primary authentication 10.1.1.1
   [Device-radius-radius1] primary accounting 10.1.1.1
   ```

   # Configure the IP addresses of the secondary authentication and accounting RADIUS servers.

   ```
   [Device-radius-radius1] secondary authentication 10.1.1.2
   [Device-radius-radius1] secondary accounting 10.1.1.2
   ```

   # Specify the shared key between the access device and the authentication server.

   ```
   [Device-radius-radius1] key authentication simple name
   ```

   # Specify the shared key between the access device and the accounting server.

   ```
   [Device-radius-radius1] key accounting simple money
   ```

   # Exclude the ISP domain names from the usernames sent to the RADIUS servers.

   ```
   [Device-radius-radius1] user-name-format without-domain
   [Device-radius-radius1] quit
   ```

   NOTE:

   The access device must use the same username format as the RADIUS server. If the RADIUS server includes the ISP domain name in the username, so must the access device.

5. Configure an ISP domain on the access device:

   # Create an ISP domain named **bbb** and enter ISP domain view.

   ```
   [Device] domain bbb
   ```

   # Apply RADIUS scheme **radius1** to the ISP domain, and specify local authentication as the secondary authentication method.

   ```
   [Device-isp-bbb] authentication lan-access radius-scheme radius1 local
   [Device-isp-bbb] authorization lan-access radius-scheme radius1 local
   [Device-isp-bbb] accounting lan-access radius-scheme radius1 local
   [Device-isp-bbb] quit
   ```

6. Configure 802.1X on the access device:

   # Enable 802.1X on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] dot1x
   ```

   # Enable MAC-based access control on the port. By default, the port uses MAC-based access control.

   ```
   [Device-GigabitEthernet1/0/1] dot1x port-method macbased
   ```

Specify ISP domain **bbb** as the mandatory domain.

```
[Device-GigabitEthernet1/0/1] dot1x mandatory-domain bbb
[Device-GigabitEthernet1/0/1] quit
```

Enable 802.1X globally.

```
[Device] dot1x
```

7. Configure the 802.1X client. If an iNode client is used, do not select the **Carry version info** option in the client configuration. (Details not shown.)

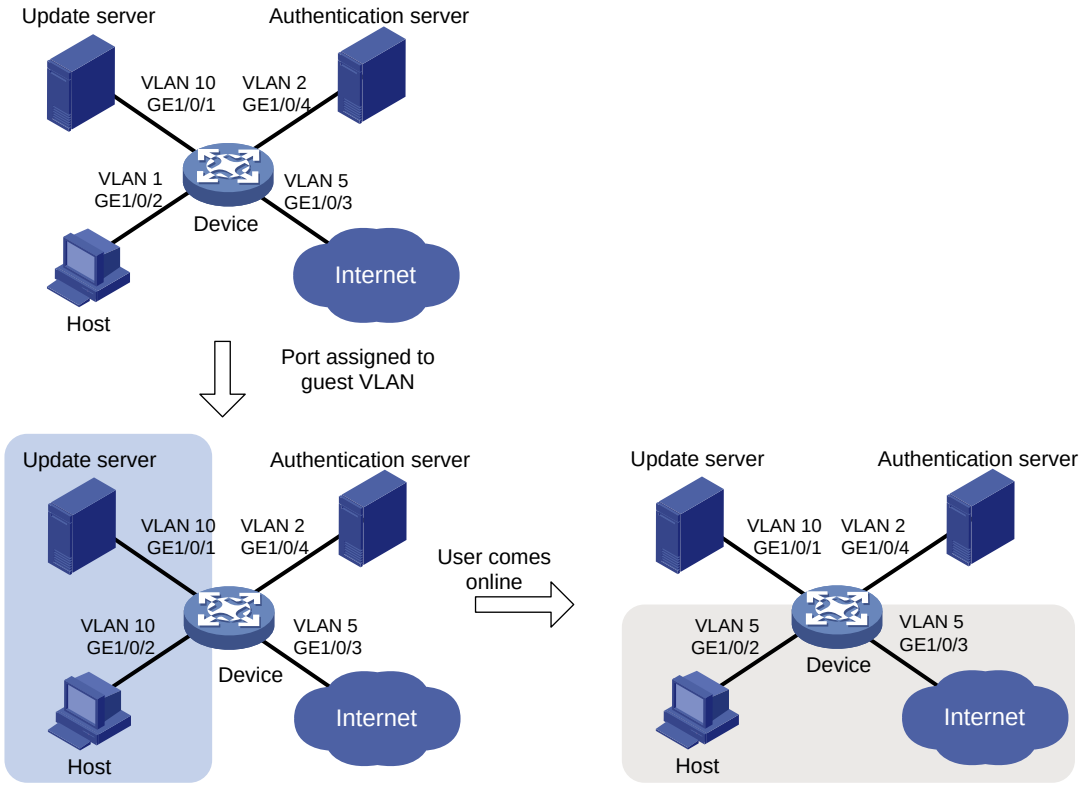
Verifying the configuration

Verify the 802.1X configuration on GigabitEthernet 1/0/1.

```
[Device] display dot1x interface gigabitethernet 1/0/1
```

Display the user connection information after an 802.1X user passes authentication.

```
[Device] display dot1x connection
```



Example: Configuring 802.1X guest VLAN and authorization VLAN

Network configuration

As shown in Figure 13:

- Use RADIUS servers to perform authentication, authorization, and accounting for 802.1X users that connect to GigabitEthernet 1/0/2. Implement port-based access control on the port.
- Configure VLAN 10 as the 802.1X guest VLAN on GigabitEthernet 1/0/2. The host and the update server are both in VLAN 10, and the host can access the update server and download the 802.1X client software.
- Configure a QoS policy to deny packets destined for the Internet (5.1.1.1) and apply the QoS policy to the outbound direction of VLAN 10. The configuration prevents users in the 802.1X guest VLAN from accessing the Internet before they pass 802.1X authentication.
- After the host passes 802.1X authentication, the access device assigns the host to VLAN 5 where GigabitEthernet 1/0/3 is. The host can access the Internet.

Figure 13 Network diagram

Procedure

For information about the RADIUS commands used on the access device in this example, see *Security Command Reference*.

1. Configure the RADIUS server to provide authentication, authorization, and accounting services. Configure user accounts and authorization VLAN (VLAN 5 in this example) for the users. (Details not shown.)
2. Create VLANs, and assign ports to the VLANs on the access device.

   NOTE:

   By default, VLAN 1 exists and all ports belong to the VLAN. You do not need to create the VLAN or assign GigabitEthernet 1/0/2 to the VLAN.

   ```
   <Device> system-view
   [Device] vlan 10
   [Device-vlan10] port gigabitethernet 1/0/1
   [Device-vlan10] quit
   [Device] vlan 2
   [Device-vlan2] port gigabitethernet 1/0/4
   [Device-vlan2] quit
   [Device] vlan 5
   [Device-vlan5] port gigabitethernet 1/0/3
   [Device-vlan5] quit
   ```

3. Configure a QoS policy:

   # Configure advanced ACL 3000 to match packets destined for 5.1.1.1.

   ```
   [Device] acl advanced 3000
   ```

```
[Device-acl-ipv4-adv-3000] rule permit ip destination 5.1.1.1 0.0.0.255
[Device-acl-ipv4-adv-3000] quit
```

Specify advanced ACL 3000 in traffic class **classifier_1** to match traffic.

```
[Device] traffic classifier classifier_1
[Device-classifier-classifier_1] if-match acl 3000
[Device-classifier-classifier_1] quit
```

Configure traffic behavior **behavior_1** to deny matching packets.

```
[Device] traffic behavior behavior_1
[Device-behavior-behavior_1] filter deny
[Device-behavior-behavior_1] quit
```

Configure QoS policy **policy_1** to associate traffic class **classifier_1** with traffic behavior **behavior_1**.

```
[Device] qos policy policy_1
[Device-qospolicy-policy_1] classifier classifier_1 behavior behavior_1
[Device-qospolicy-policy_1] quit
```

Apply QoS policy **policy_1** to the outbound direction of VLAN 10.

```
[Device] qos vlan-policy policy_1 vlan 10 outbound
```

4. Configure a RADIUS scheme on the access device:

Create RADIUS scheme **2000** and enter RADIUS scheme view.

```
[Device] radius scheme 2000
```

Specify the server at 10.11.1.1 as the primary authentication server, and set the authentication port to 1812.

```
[Device-radius-2000] primary authentication 10.11.1.1 1812
```

Specify the server at 10.11.1.1 as the primary accounting server, and set the accounting port to 1813.

```
[Device-radius-2000] primary accounting 10.11.1.1 1813
```

Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

```
[Device-radius-2000] key authentication simple abc
```

Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

```
[Device-radius-2000] key accounting simple abc
```

Exclude the ISP domain names from the usernames sent to the RADIUS server.

```
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

5. Configure an ISP domain on the access device:

Create ISP domain **bbb** and enter ISP domain view.

```
[Device] domain bbb
```

Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

```
[Device-isp-bbb] authentication lan-access radius-scheme 2000
[Device-isp-bbb] authorization lan-access radius-scheme 2000
[Device-isp-bbb] accounting lan-access radius-scheme 2000
[Device-isp-bbb] quit
```

6. Configure 802.1X on the access device:

Enable 802.1X on GigabitEthernet 1/0/2.

```
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] dot1x
```

Implement port-based access control on the port.

```
[Device-GigabitEthernet1/0/2] dot1x port-method portbased
```

Set the port authorization mode to **auto**. By default, the port uses the auto mode.

```
[Device-GigabitEthernet1/0/2] dot1x port-control auto
```

Specify VLAN 10 as the 802.1X guest VLAN on GigabitEthernet 1/0/2.

```
[Device-GigabitEthernet1/0/2] dot1x guest-vlan 10
[Device-GigabitEthernet1/0/2] quit
```

Enable 802.1X globally.

```
[Device] dot1x
```

7. Configure the 802.1X client. Make sure the 802.1X client can update its IP address after the access port is assigned to the guest VLAN or an authorization VLAN. (Details not shown.)

Verifying the configuration

Verify the 802.1X guest VLAN configuration on GigabitEthernet 1/0/2.

```
[Device] display dot1x interface gigabitethernet 1/0/2
```

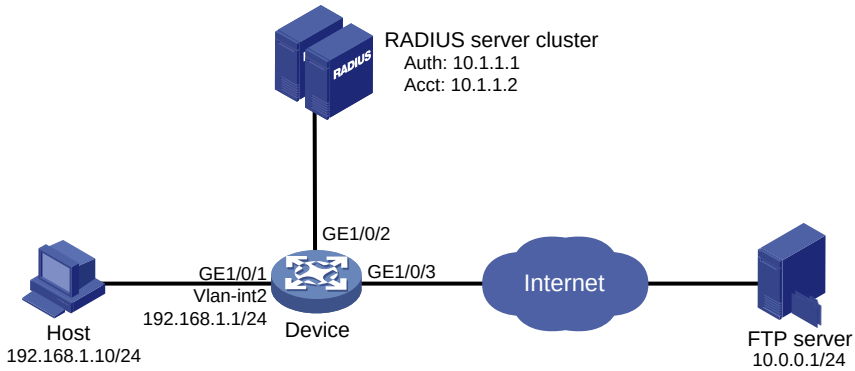
Verify that GigabitEthernet 1/0/2 is assigned to VLAN 10 before any user passes authentication on the port.

```
[Device] display vlan 10
```

After a user passes authentication, display information on GigabitEthernet 1/0/2. Verify that GigabitEthernet 1/0/2 is assigned to VLAN 5.

```
[Device] display interface gigabitethernet 1/0/2
```

Example: Configuring 802.1X with ACL assignment



Network configuration

As shown in Figure 14, the host that connects to GigabitEthernet 1/0/1 must pass 802.1X authentication to access the Internet.

Perform 802.1X authentication on GigabitEthernet 1/0/1. Use the RADIUS server at 10.1.1.1 as the authentication and authorization server, and the RADIUS server at 10.1.1.2 as the accounting server.

Configure ACL assignment on GigabitEthernet 1/0/1 to deny access of 802.1X users to the FTP server from 8:00 to 18:00 on weekdays.

Figure 14 Network diagram

Procedure

For information about the RADIUS commands used on the access device in this example, see *Security Command Reference*.

1. Configure the RADIUS servers to provide authentication, authorization, and accounting services. Add user accounts and specify the ACL (ACL 3000 in this example) for the users. (Details not shown.)
2. Assign an IP address to each interface, as shown in Figure 14. (Details not shown.)
3. Configure a RADIUS scheme on the access device:

   # Create RADIUS scheme **2000** and enter RADIUS scheme view.

   ```
   <Device> system-view
   [Device] radius scheme 2000
   ```

   # Specify the server at 10.1.1.1 as the primary authentication server, and set the authentication port to 1812.

   ```
   [Device-radius-2000] primary authentication 10.1.1.1 1812
   ```

   # Specify the server at 10.1.1.2 as the primary accounting server, and set the accounting port to 1813.

   ```
   [Device-radius-2000] primary accounting 10.1.1.2 1813
   ```

   # Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

   ```
   [Device-radius-2000] key authentication simple abc
   ```

   # Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

   ```
   [Device-radius-2000] key accounting simple abc
   ```

   # Exclude the ISP domain names from the usernames sent to the RADIUS server.

   ```
   [Device-radius-2000] user-name-format without-domain
   [Device-radius-2000] quit
   ```

4. Configure an ISP domain on the access device:

   # Create ISP domain **bbb** and enter ISP domain view.

   ```
   [Device] domain bbb
   ```

   # Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

   ```
   [Device-isp-bbb] authentication lan-access radius-scheme 2000
   [Device-isp-bbb] authorization lan-access radius-scheme 2000
   [Device-isp-bbb] accounting lan-access radius-scheme 2000
   [Device-isp-bbb] quit
   ```

5. Configure a time range named **ftp** from 8:00 to 18:00 on weekdays on the access device.

   ```
   [Device] time-range ftp 8:00 to 18:00 working-day
   ```

6. Configure ACL 3000 to deny packets destined for the FTP server at 10.0.0.1 during the specified time range on the access device.

   ```
   [Device] acl advanced 3000
   [Device-acl-ipv4-adv-3000] rule 0 deny ip destination 10.0.0.1 0 time-range ftp
   [Device-acl-ipv4-adv-3000] quit
   ```

7. Configure 802.1X on the access device:

   # Enable 802.1X on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] dot1x
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Enable 802.1X globally.

   ```
   [Device] dot1x
   ```

8. Configure the 802.1X client. Make sure the client is able to update its IP address after the access port is assigned to the 802.1X guest VLAN or an authorization VLAN. (Details not shown.)

Verifying the configuration

Use the user account to pass authentication. (Details not shown.)

Verify that the user cannot ping the FTP server at any time from 8:00 to 18:00 on any weekday.

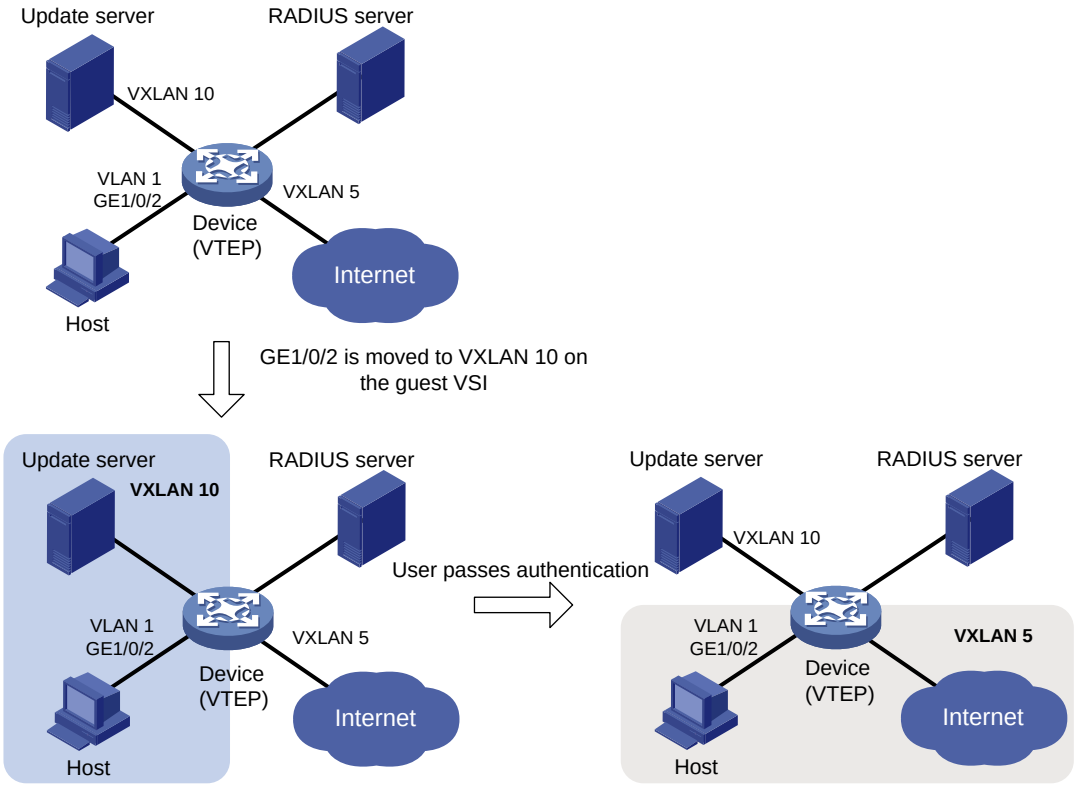
```
C:\>ping 10.0.0.1

Pinging 10.0.0.1 with 32 bytes of data:

Request timed out.
Request timed out.
Request timed out.
Request timed out.

Ping statistics for 10.0.0.1:
    Packets: Sent = 4, Received = 0, Lost = 4 (100% loss),
```

The output shows that ACL 3000 is active on the user, and the user cannot access the FTP server.



Example: Configuring 802.1X guest VSI and authorization VSI configuration (port-based)

Network configuration

As shown in Figure 15:

- The device acts as both a VXLAN VTEP and a network access device. It uses the RADIUS server to perform authentication, authorization, and accounting for 802.1X users that connect to GigabitEthernet 1/0/2.
- GigabitEthernet 1/0/2 uses port-based access control and is configured with the 802.1X guest VSI. VXLAN 10 is created on the guest VSI. Users in the guest VSI can access the update server in VXLAN 10 and download the 802.1X client software.
- The RADIUS server assigns an authorization VSI to the host. The VSI is associated with VXLAN 5 on the device. After passing authentication, the host can access the Internet.

Figure 15 Network diagram

Procedure

For information about the RADIUS commands used on the access device in this example, see *Security Command Reference*.

1. Configure the RADIUS server to provide authentication, authorization, and accounting services. Configure user accounts and authorization VSI (VSI **vpn5** in this example) for the users. (Details not shown.)

   If an ADCAM server is used for authentication and authorization, configure VSIs on the server. The server will assign these VSIs to the device. You do not need to configure VSIs on the device.

2. Enable L2VPN on the access device.

   ```
   <Device> system-view
   [Device] l2vpn enable
   ```

3. Create VSIs and the corresponding VXLANs on the access device.

   ```
   [Device] vsi vpn10
   [Device-vsi-vpn10] vxlan 10
   [Device-vsi-vpn10-vxlan-10] quit
   [Device-vsi-vpn10] quit
   [Device] vsi vpn5
   [Device-vsi-vpn5] vxlan 5
   [Device-vsi-vpn5-vxlan-5] quit
   [Device-vsi-vpn5] quit
   ```

4. Configure a RADIUS scheme on the access device:

   # Create RADIUS scheme **2000** and enter RADIUS scheme view.

   ```
   [Device] radius scheme 2000
   ```

Specify the server at 10.11.1.1 as the primary authentication server, and set the authentication port to 1812.

```
[Device-radius-2000] primary authentication 10.11.1.1 1812
```

Specify the server at 10.11.1.1 as the primary accounting server, and set the accounting port to 1813.

```
[Device-radius-2000] primary accounting 10.11.1.1 1813
```

Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

```
[Device-radius-2000] key authentication simple abc
```

Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

```
[Device-radius-2000] key accounting simple abc
```

Exclude the ISP domain names from the usernames sent to the authentication and accounting servers.

```
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

5. Configure an ISP domain on the access device:

Create ISP domain **bbb** and enter ISP domain view.

```
[Device] domain bbb
```

Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

```
[Device-isp-bbb] authentication lan-access radius-scheme 2000
[Device-isp-bbb] authorization lan-access radius-scheme 2000
[Device-isp-bbb] accounting lan-access radius-scheme 2000
[Device-isp-bbb] quit
```

6. Configure 802.1X on the access device:

Enable 802.1X on GigabitEthernet 1/0/2.

```
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] dot1x
```

Implement port-based access control on the port.

```
[Device-GigabitEthernet1/0/2] dot1x port-method portbased
```

Set the port authorization mode to **auto**. By default, the port uses the auto mode.

```
[Device-GigabitEthernet1/0/2] dot1x port-control auto
```

Specify VSI **vpn10** as the 802.1X guest VSI on GigabitEthernet 1/0/2.

```
[Device-GigabitEthernet1/0/2] dot1x guest-vsi vpn10
[Device-GigabitEthernet1/0/2] quit
```

Enable 802.1X globally.

```
[Device] dot1x
```

7. Configure the 802.1X client. Make sure the 802.1X client can update its IP address after the access port is assigned to the guest VSI or an authorization VSI. (Details not shown.)

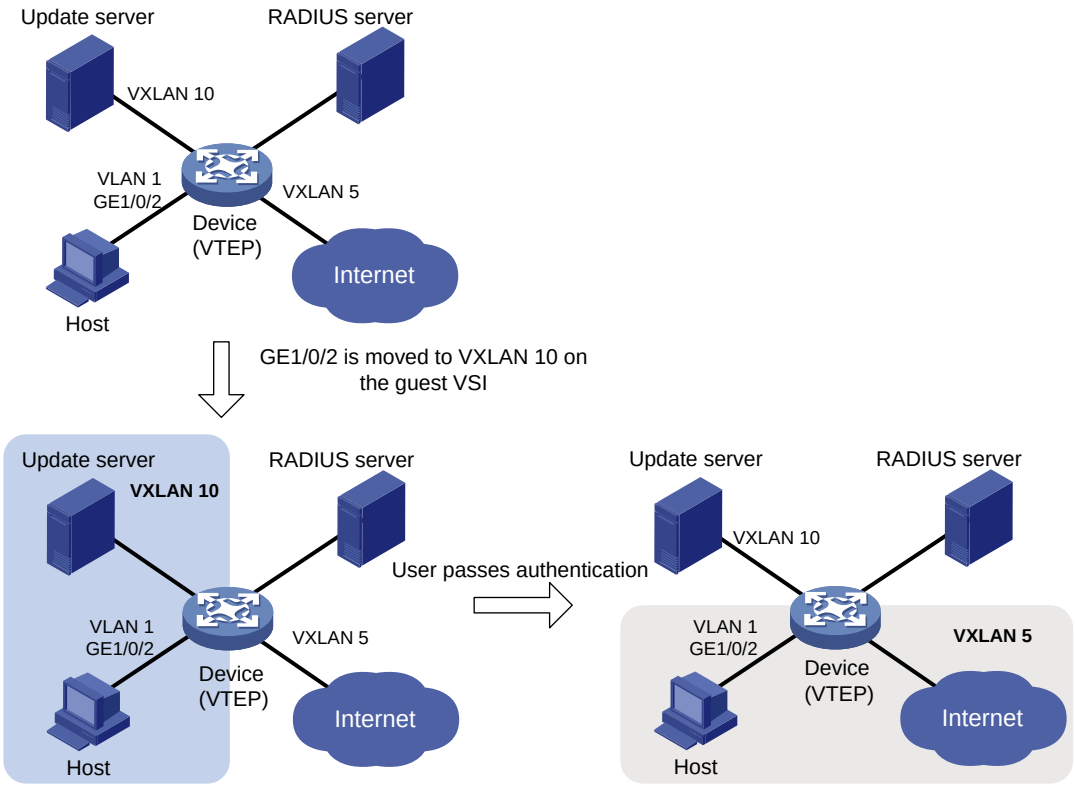
Verifying the configuration

Verify that GigabitEthernet 1/0/2 is assigned to VSI **vpn10** before any user passes authentication on the port.

```
[Device] display l2vpn forwarding ac verbose
```

Verify that GigabitEthernet 1/0/2 is assigned to VSI **vpn5** after a user passes authentication on the port.

```
[Device] display l2vpn forwarding ac verbose
```



Example: Configuring 802.1X guest VSI and authorization VSI (MAC-based)

Network configuration

As shown in Figure 16:

- The device acts as both a VXLAN VTEP and a network access device. It uses the RADIUS server to perform authentication, authorization, and accounting for 802.1X users that connect to GigabitEthernet 1/0/2.
- GigabitEthernet 1/0/2 uses MAC-based access control and is configured with the 802.1X guest VSI. VXLAN 10 is created on the guest VSI. Users in the guest VSI can access the update server in VXLAN 10 and download the 802.1X client software.
- The RADIUS server assigns an authorization VSI to the host. The VSI is associated with VXLAN 5 on the device. After passing authentication, the host can access the Internet.

Figure 16 Network diagram

Procedure

For information about the RADIUS commands used on the access device in this example, see *Security Command Reference*.

1. Configure the RADIUS server to provide authentication, authorization, and accounting services. Configure user accounts and authorization VSI (VSI **vpn5** in this example) for the users. (Details not shown.)

   If an ADCAM server is used for authentication and authorization, configure VSIs on the server. The server will assign these VSIs to the device. You do not need to configure VSIs on the device.

2. Enable L2VPN on the access device.

```
<Device> system-view
[Device] l2vpn enable
```

3. Create VSIs and the corresponding VXLANs on the access device.

```
[Device] vsi vpn10
[Device-vsi-vpn10] vxlan 10
[Device-vsi-vpn10-vxlan-10] quit
[Device-vsi-vpn10] quit
[Device] vsi vpn5
[Device-vsi-vpn5] vxlan 5
[Device-vsi-vpn5-vxlan-5] quit
[Device-vsi-vpn5] quit
```

4. Configure a RADIUS scheme on the access device:

   # Create RADIUS scheme **2000** and enter RADIUS scheme view.

```
[Device] radius scheme 2000
```

   # Specify the server at 10.11.1.1 as the primary authentication server, and set the authentication port to 1812.

```
[Device-radius-2000] primary authentication 10.11.1.1 1812
```

   # Specify the server at 10.11.1.1 as the primary accounting server, and set the accounting port to 1813.

```
[Device-radius-2000] primary accounting 10.11.1.1 1813
```

   # Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

```
[Device-radius-2000] key authentication simple abc
```

   # Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

```
[Device-radius-2000] key accounting simple abc
```

   # Exclude the ISP domain names from the usernames sent to the authentication and accounting servers.

```
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

5. Configure an ISP domain on the access device:

   # Create ISP domain **bbb** and enter ISP domain view.

```
[Device] domain bbb
```

   # Apply RADIUS scheme **2000** to the ISP domain for authentication, authorization, and accounting.

```
[Device-isp-bbb] authentication lan-access radius-scheme 2000
[Device-isp-bbb] authorization lan-access radius-scheme 2000
[Device-isp-bbb] accounting lan-access radius-scheme 2000
[Device-isp-bbb] quit
```

6. Configure 802.1X on the access device:

   # Enable 802.1X on GigabitEthernet 1/0/2.

```
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] dot1x
```

   # Set the port authorization mode to **auto**. By default, the port uses the auto mode.

```
[Device-GigabitEthernet1/0/2] dot1x port-control auto
```

   # Enable MAC-based traffic matching for dynamic Ethernet service instances on GigabitEthernet 1/0/2.

```
[Device-GigabitEthernet1/0/2] mac-based ac
```

Enable 802.1X unicast trigger on GigabitEthernet 1/0/2.

```
[Device-GigabitEthernet1/0/2] dot1x unicast-trigger
```

Specify VSI **vpn10** as the 802.1X guest VSI on GigabitEthernet 1/0/2.

```
[Device-GigabitEthernet1/0/2] dot1x guest-vsi vpn10
[Device-GigabitEthernet1/0/2] quit
```

Enable 802.1X globally.

```
[Device] dot1x
```

7. Configure the 802.1X client. Make sure the 802.1X client can update its IP address after the access port is assigned to the guest VSI or an authorization VSI. (Details not shown.)

Verifying the configuration

Verify that GigabitEthernet 1/0/2 is assigned to VSI **vpn10** if no responses are received from the client after 802.1X authentication is triggered.

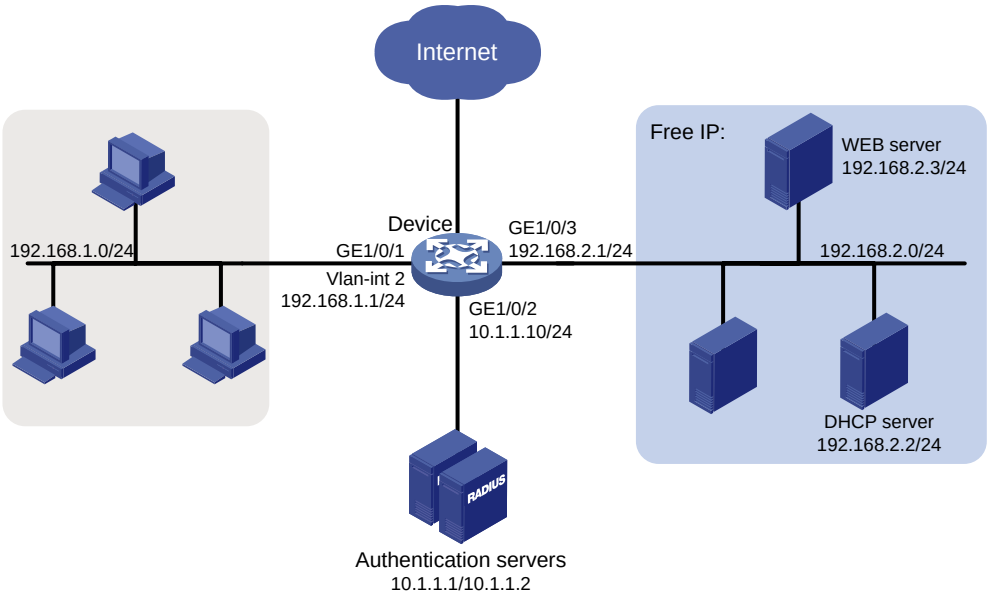
```
[Device] display l2vpn forwarding ac verbose
```

Verify that GigabitEthernet 1/0/2 is assigned to VSI **vpn5** after a user passes authentication on the port.

```
[Device] display l2vpn forwarding ac verbose
```

Example: Configuring 802.1X with EAD assistant (with DHCP relay agent)

Network configuration



As shown in Figure 17:

- The intranet 192.168.1.0/24 is attached to GigabitEthernet 1/0/1 of the access device.
- The hosts use DHCP to obtain IP addresses.
- A DHCP server and a Web server are deployed on the 192.168.2.0/24 subnet for users to obtain IP addresses and download client software.

Deploy an EAD solution for the intranet to meet the following requirements:

- Allow unauthenticated users and users that have failed 802.1X authentication to access 192.168.2.0/24. The users can obtain IP addresses and download software.
- If these users use a Web browser to access a network other than 192.168.2.0/24, redirect them to the Web server for 802.1X client downloading.
- Allow authenticated 802.1X users to access the network.

Figure 17 Network diagram

Procedure

1. Make sure the DHCP server, the Web server, and the authentication servers have been configured correctly. (Details not shown.)
2. Configure an IP address for each interface. (Details not shown.)
3. Configure DHCP relay:

   # Enable DHCP.

   ```
   <Device> system-view
   [Device] dhcp enable
   ```

   # Enable the DHCP relay agent on VLAN-interface 2.

   ```
   [Device] interface vlan-interface 2
   [Device-Vlan-interface2] dhcp select relay
   ```

   # Specify the DHCP server 192.168.2.2 on the relay agent interface VLAN-interface 2.

   ```
   [Device-Vlan-interface2] dhcp relay server-address 192.168.2.2
   [Device-Vlan-interface2] quit
   ```

4. Configure a RADIUS scheme:

   # Create RADIUS scheme **2000** and enter RADIUS scheme view.

   ```
   [Device] radius scheme 2000
   ```

   # Specify the server at 10.1.1.1 as the primary authentication server, and set the authentication port to 1812.

   ```
   [Device-radius-2000] primary authentication 10.1.1.1 1812
   ```

   # Specify the server at 10.1.1.2 as the primary accounting server, and set the accounting port to 1813.

   ```
   [Device-radius-2000] primary accounting 10.1.1.2 1813
   ```

   # Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

   ```
   [Device-radius-2000] key authentication simple abc
   ```

   # Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

   ```
   [Device-radius-2000] key accounting simple abc
   ```

Exclude the ISP domain names from the usernames sent to the RADIUS server.

```
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

5. Configure an ISP domain:

   # Create ISP domain **bbb** and enter ISP domain view.

   ```
   [Device] domain bbb
   ```

   # Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

   ```
   [Device-isp-bbb] authentication lan-access radius-scheme 2000
   [Device-isp-bbb] authorization lan-access radius-scheme 2000
   [Device-isp-bbb] accounting lan-access radius-scheme 2000
   [Device-isp-bbb] quit
   ```

6. Configure 802.1X:

   # Configure the free IP.

   ```
   [Device] dot1x ead-assistant free-ip 192.168.2.0 24
   ```

   # Configure the redirect URL for client software download.

   ```
   [Device] dot1x ead-assistant url https://192.168.2.3
   ```

   # Enable the EAD assistant feature.

   ```
   [Device] dot1x ead-assistant enable
   ```

   # Enable 802.1X on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] dot1x
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Enable 802.1X globally.

   ```
   [Device] dot1x
   ```

Verifying the configuration

Verify the 802.1X configuration.

```
[Device] display dot1x
```

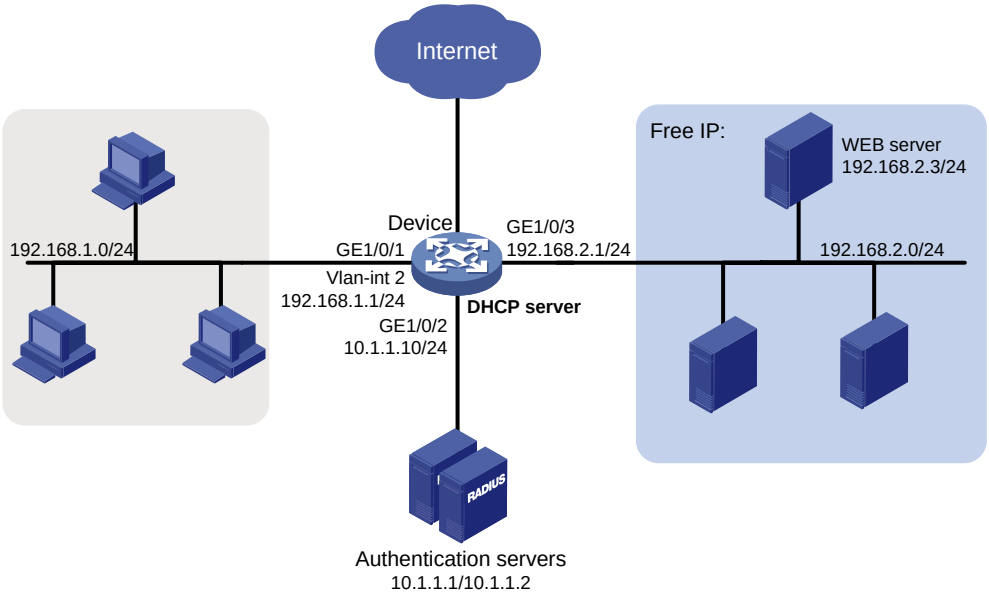
Verify that you can ping an IP address on the free IP subnet from a host before the user on the host passes 802.1X authentication. (Details not shown.)

Verify that you are redirected to the Web server when you enter in your Web browser an IP address not on the free IP. (Details not shown.)

Example: Configuring 802.1X with EAD assistant (with DHCP server)

Network configuration

As shown in Figure 18:



- The intranet 192.168.1.0/24 is attached to GigabitEthernet 1/0/1 of the access device.
- The hosts use DHCP to obtain IP addresses.
- A Web server is deployed on the 192.168.2.0/24 subnet for users to download client software.

Deploy an EAD solution for the intranet to meet the following requirements:

- Allow unauthenticated users and users that have failed 802.1X authentication to access 192.168.2.0/24. The users can download software.

- If these users use a Web browser to access a network other than 192.168.2.0/24, redirect them to the Web server for 802.1X client downloading.
- Allow authenticated 802.1X users to access the network.

Figure 18 Network diagram

Procedure

1. Make sure the Web server and the authentication servers have been configured correctly. (Details not shown.)
2. Configure an IP address for each interface. (Details not shown.)
3. Configure the DHCP server:

   # Enable DHCP.

   ```
   <Device> system-view
   [Device] dhcp enable
   ```

   # Enable the DHCP server on VLAN-interface 2.

   ```
   [Device] interface vlan-interface 2
   [Device-Vlan-interface2] dhcp select server
   [Device-Vlan-interface2] quit
   ```

   # Create DHCP address pool **0**.

   ```
   [Device] dhcp server ip-pool 0
   ```

   # Specify subnet 192.168.1.0/24 in DHCP address pool 0.

   ```
   [Device-dhcp-pool-0] network 192.168.1.0 mask 255.255.255.0
   ```

   # Specify the gateway address 192.168.1.1 in DHCP address pool 0.

   ```
   [Device-dhcp-pool-0] gateway-list 192.168.1.1
   [Device-dhcp-pool-0] quit
   ```

4. Configure a RADIUS scheme:

   # Create RADIUS scheme **2000** and enter RADIUS scheme view.

   ```
   [Device] radius scheme 2000
   ```

   # Specify the server at 10.1.1.1 as the primary authentication server, and set the authentication port to 1812.

   ```
   [Device-radius-2000] primary authentication 10.1.1.1 1812
   ```

Specify the server at 10.1.1.2 as the primary accounting server, and set the accounting port to 1813.

```
[Device-radius-2000] primary accounting 10.1.1.2 1813
```

Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

```
[Device-radius-2000] key authentication simple abc
```

Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

```
[Device-radius-2000] key accounting simple abc
```

Exclude the ISP domain names from the usernames sent to the RADIUS server.

```
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

5. Configure an ISP domain:

Create ISP domain **bbb** and enter ISP domain view.

```
[Device] domain bbb
```

Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

```
[Device-isp-bbb] authentication lan-access radius-scheme 2000
[Device-isp-bbb] authorization lan-access radius-scheme 2000
[Device-isp-bbb] accounting lan-access radius-scheme 2000
[Device-isp-bbb] quit
```

6. Configure 802.1X:

Configure the free IP.

```
[Device] dot1x ead-assistant free-ip 192.168.2.0 24
```

Configure the redirect URL for client software download.

```
[Device] dot1x ead-assistant url https://192.168.2.3
```

Enable the EAD assistant feature.

```
[Device] dot1x ead-assistant enable
```

Enable 802.1X on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] dot1x
[Device-GigabitEthernet1/0/1] quit
```

Enable 802.1X globally.

```
[Device] dot1x
```

Verifying the configuration

Verify the 802.1X configuration.

```
[Device] display dot1x
```

Verify that you can ping an IP address on the free IP subnet from a host before the user on the host passes 802.1X authentication. (Details not shown.)

Verify that you are redirected to the Web server when you enter in your Web browser an IP address not on the free IP. (Details not shown.)

Troubleshooting 802.1X

EAD assistant Web redirection failure

Symptom

Unauthenticated users are not redirected to the specified URL server after they enter external website addresses in their Web browsers.

Analysis

Redirection will not happen for one of the following reasons:

- The address is in the string format. The operating system of the host regards the string as a website name and tries to resolve the string. If the resolution fails, the operating system sends an ARP request, but the target address is not in the dotted decimal notation. The redirection feature does redirect this kind of ARP request.
- The address is within a free IP segment or free microsegment. No redirection will take place, even if no host is present with the address.
- The server is not in a free IP segment or free microsegment.
- No server is using the redirect URL, or the server with the URL does not provide Web services.

Solution

To resolve the issue:

1. Enter a dotted decimal IP address that is not in any free IP segments or free microsegments.
2. Verify that the access device and the server are configured correctly.
3. If the issue persists, contact H3C Support.

Configuring MAC authentication

About MAC authentication

MAC authentication controls network access by authenticating source MAC addresses on a port. The feature does not require client software, and users do not have to enter a username and password for network access. The device initiates a MAC authentication process when it detects an unknown source MAC address on a MAC authentication-enabled port. If the MAC address passes authentication, the user can access authorized network resources. If the authentication fails, the device marks the MAC address as a silent MAC address, drops the packet, and starts a quiet timer. The device drops all subsequent packets from the MAC address within the quiet time. The quiet mechanism avoids repeated authentication during a short time.

User account policies

MAC authentication supports the following user account policies:

- **Global user account policy**, which can be either of the following options:
  - **MAC-based user account policy**—One MAC-based user account for each user. As shown in Figure 1, the access device uses the source MAC addresses in packets as the usernames and passwords of users for MAC authentication. This policy is suitable for an insecure environment.

    NOTE:

    MAC-based user account policy also supports configuring a password shared by all MAC-based user accounts.

  - **Shared user account policy**—One shared user account for all users. You specify one username and password (which are not necessarily a MAC address) for all MAC authentication users on the access device, as shown in Figure 2. This policy is suitable for a secure environment.
- **MAC range-specific user account policy**—One shared user account for users in a specific MAC address range. You specify one username and password (which are not necessarily a MAC address) for users in a specific MAC address range on the access device, as shown in Figure 3. For example, you can specify a username and password for users with a specific OUI for MAC authentication.

IMPORTANT:

- You can use global and MAC range-specific user account policies together. For users in a MAC address range, the MAC range-specific user account settings have higher priority than the global user account settings.
- If a RADIUS server is used for MAC authentication, you must create the user accounts on the RADIUS server based on the user account policy on the access device.

Figure 1 MAC-based user account policy

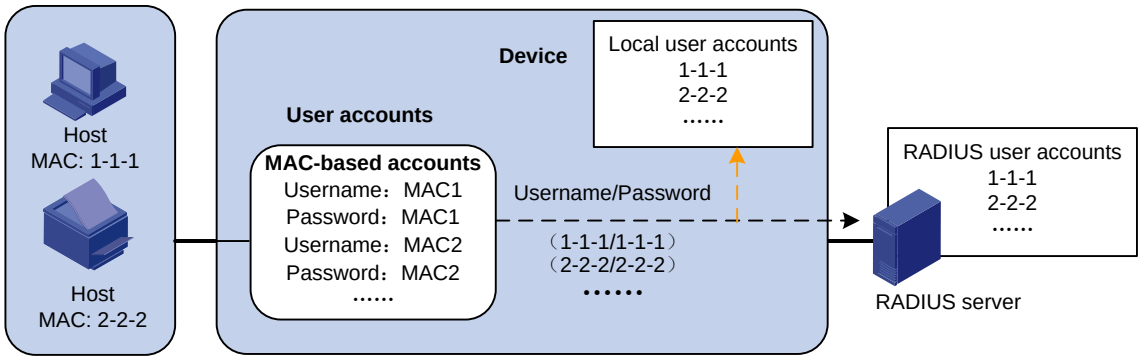

Figure 2 Shared user account policy (global)

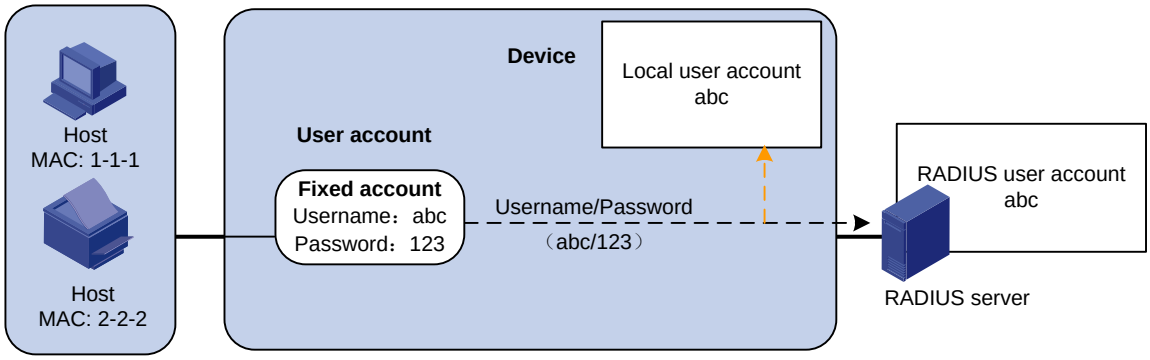

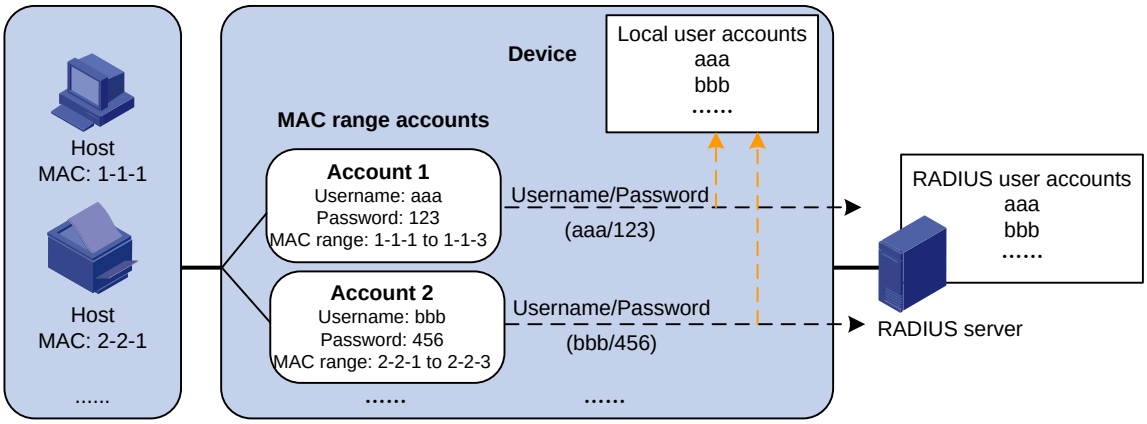

Figure 3 Shared user account policy (specific to MAC address ranges)

Authentication methods

You can perform MAC authentication on the access device (local authentication) or through a RADIUS server.

For more information about configuring local authentication and RADIUS authentication, see "Configuring AAA."

RADIUS authentication

If MAC-based accounts are used, the access device by default sends the source MAC address of a packet as the username and password to the RADIUS server for authentication. If a password is

configured for MAC-based accounts, the access device sends the configured password as the password to the RADIUS server.

If a shared account is used, the access device sends the shared account username and password to the RADIUS server for authentication.

The access device and the RADIUS server use Password Authentication Protocol (PAP) or Challenge Handshake Authentication Protocol (CHAP) for communication.

Local authentication

If MAC-based accounts are used, the access device by default uses the source MAC address of a packet as the username and password to search the local account database for a match. If a password is configured for MAC-based accounts, the device uses the configured password to search the local account database for a match.

If a shared account is used, the access device uses the shared account username and password to search the local account database for a match.

VLAN assignment

Authorization VLAN

The authorization VLAN controls the access of a MAC authentication user to authorized network resources. The device supports authorization VLANs assigned locally or by a remote server.

IMPORTANT:

Only remote servers can assign tagged authorization VLANs.

Remote VLAN authorization

In remote VLAN authorization, you must configure an authorization VLAN for a user on the remote server. After the user authenticates to the server, the server assigns authorization VLAN information to the device. Then, the device assigns the user access port to the authorization VLAN as a tagged or untagged member.

The device supports assignment of the following authorization VLAN information by the remote server:

- VLAN ID.
- VLAN name, which must be the same as the VLAN description on the access device.
- A string of VLAN IDs and VLAN names.

  In the string, some VLANs are represented by their IDs, and some VLANs are represented by their names.
- VLAN group name.

  For more information about VLAN groups, see *Layer 2—LAN Switching Configuration Guide*.
- VLAN ID with a suffix of **t** or **u**.

  The **t** and **u** suffixes require the device to assign the access port to the VLAN as a tagged or untagged member, respectively. For example, **2u** indicates assigning the port to VLAN 2 as an untagged member.

If a VLAN name or VLAN group name is assigned, the device converts the information into a VLAN ID before VLAN assignment.

IMPORTANT:

For a VLAN represented by its VLAN name to be assigned successfully, you must make sure the VLAN has been created on the device.

To assign VLAN IDs with suffixes, make sure the user access port is a hybrid or trunk port.

IMPORTANT:

To ensure a successful assignment, the authorization VLANs assigned by the remote server cannot be any of the following types:

- Dynamically learned VLANs.
- Reserved VLANs.

If the server assigns a group of VLANs, the access device selects a VLAN as described in Table 1.

Table 1 Authorization VLAN selection from a group of VLANs

VLAN information	Authorization VLAN selection
VLANs by IDs VLANs by names VLAN group name	The device selects an authorization VLAN from the VLAN group for a user according to the following rules: • On a hybrid port with MAC-based VLAN enabled: ○ If the port does not have online users, the device selects the VLAN with the lowest ID. ○ If the port has online users, the device selects the VLAN that has the fewest online users. If two VLANs have the same number of online MAC authentication users, the device selects the VLAN with the lower ID. • On an access, trunk, or MAC-based VLAN disabled hybrid port: ○ If the port does not have online users, the device selects the VLAN with the lowest ID. ○ If the port has online users, the device examines the VLAN group for the VLAN of the online users. If the VLAN is found, the VLAN is assigned to the user as the authorization VLAN. If the VLAN is not found, VLAN authorization fails.
VLAN IDs with suffixes	1. The device selects the leftmost VLAN ID without a suffix, or the leftmost VLAN ID suffixed by **u** as an untagged VLAN, whichever is more leftmost. 2. The device assigns the untagged VLAN to the port as the PVID, and it assigns the remaining as tagged VLANs. If no untagged VLAN is assigned, the PVID of the port does not change. The port permits traffic from these tagged and untagged VLANs to pass through. For example, the authentication server sends the string **1u 2t 3** to the access device for a user. The device assigns VLAN 1 as an untagged VLAN and all remaining VLANs (including VLAN 3) as tagged VLANs. VLAN 1 becomes the PVID.

Local VLAN authorization

To perform local VLAN authorization for a user, specify the VLAN ID in the authorization attribute list of the local user account for that user. For each local user, you can specify only one authorization VLAN ID. The user access port is assigned to the VLAN as an untagged member.

IMPORTANT:

Local VLAN authorization does not support assignment of tagged VLANs.

For more information about local user configuration, see "Configuring AAA."

Authorization VLAN manipulation on a MAC authentication-enabled port

Table 2 describes the way the network access device handles authorization VLANs (except for the VLANs specified with suffixes) for MAC authenticated users on a port.

Table 2 VLAN manipulation

Port type	VLAN manipulation
• Access port • Trunk port • Hybrid port with MAC-based VLAN disabled	• The device assigns the port to the first authenticated user's authorization VLAN and sets the VLAN as the PVID if that authorization VLAN has the untagged attribute. • If the authorization VLAN has the tagged attribute, the device assigns the port to the authorization VLAN without changing its PVID. **NOTE:** The tagged attribute is supported only on trunk and hybrid ports.
Hybrid port with MAC-based VLAN enabled	The device maps the MAC address of each user to its own authorization VLAN regardless of whether the port is a tagged member. The PVID of the port does not change.

IMPORTANT:

- If the users are attached to a port whose link type is access, make sure the authorization VLAN assigned by the server has the untagged attribute. VLAN assignment will fail if the server issues a VLAN that has the tagged attribute.
- When you assign VLANs to users attached to a trunk port or a MAC-based VLAN disabled hybrid port, make sure there is only one untagged VLAN. If a different untagged VLAN is assigned to a subsequent user, the user cannot pass authentication.
- As a best practice to enhance network security, do not use the **`port hybrid vlan`** command to assign a hybrid port to an authorization VLAN as a tagged member.

The VLAN assigned by the server to a user as an authorization VLAN might have been configured on the user access port but with a different tagging mode. For example, the server assigns an authorization VLAN with the tagged attribute, but the same VLAN configured on the port has the untagged attribute. In this situation, the VLAN settings that take effect on the user depend on the link type of the port.

- If the link type of the port is access or trunk, the authorization VLAN settings assigned by the server always take effect on the user as long as the user is online. After the user goes offline, the VLAN settings on the port take effect.
- If the link type of the port is hybrid, the VLAN settings configured on the port take effect. For example, the server assigns VLAN 30 with the untagged attribute to a user on the hybrid port. However, VLAN 30 has been configured on the port with the tagged attribute by using the **`port hybrid vlan tagged`** command. Then, the VLAN has the tagged attribute on the port.

For a MAC authenticated user to access the network on a hybrid port when no authorization VLAN is configured for the user, perform one of the following tasks:

- If the port receives tagged authentication packets from the user in a VLAN, use the **`port hybrid vlan`** command to configure the port as a tagged member in the VLAN.
- If the port receives untagged authentication packets from the user in a VLAN, use the **`port hybrid vlan`** command to configure the port as an untagged member in the VLAN.

Guest VLAN

The MAC authentication guest VLAN on a port accommodates users that have failed MAC authentication for any reason other than server unreachable. For example, the VLAN accommodates users with invalid passwords entered.

You can deploy a limited set of network resources in the MAC authentication guest VLAN. For example, a software server for downloading software and system patches.

A hybrid port is always assigned to a MAC authentication guest VLAN as an untagged member. After the assignment, do not reconfigure the port as a tagged member in the VLAN.

The device reauthenticates users in the MAC authentication guest VLAN at a specific interval. Table 3 shows the way that the network access device handles guest VLANs for MAC authentication users.

Table 3 VLAN manipulation

Authentication status	VLAN manipulation
A user in the MAC authentication guest VLAN fails MAC authentication.	The user is still in the MAC authentication guest VLAN.
A user in the MAC authentication guest VLAN passes MAC authentication.	The device remaps the MAC address of the user to the authorization VLAN assigned by the authentication server. If no authorization VLAN is configured for the user on the authentication server, the device remaps the MAC address of the user to the PVID of the port.

Critical VLAN

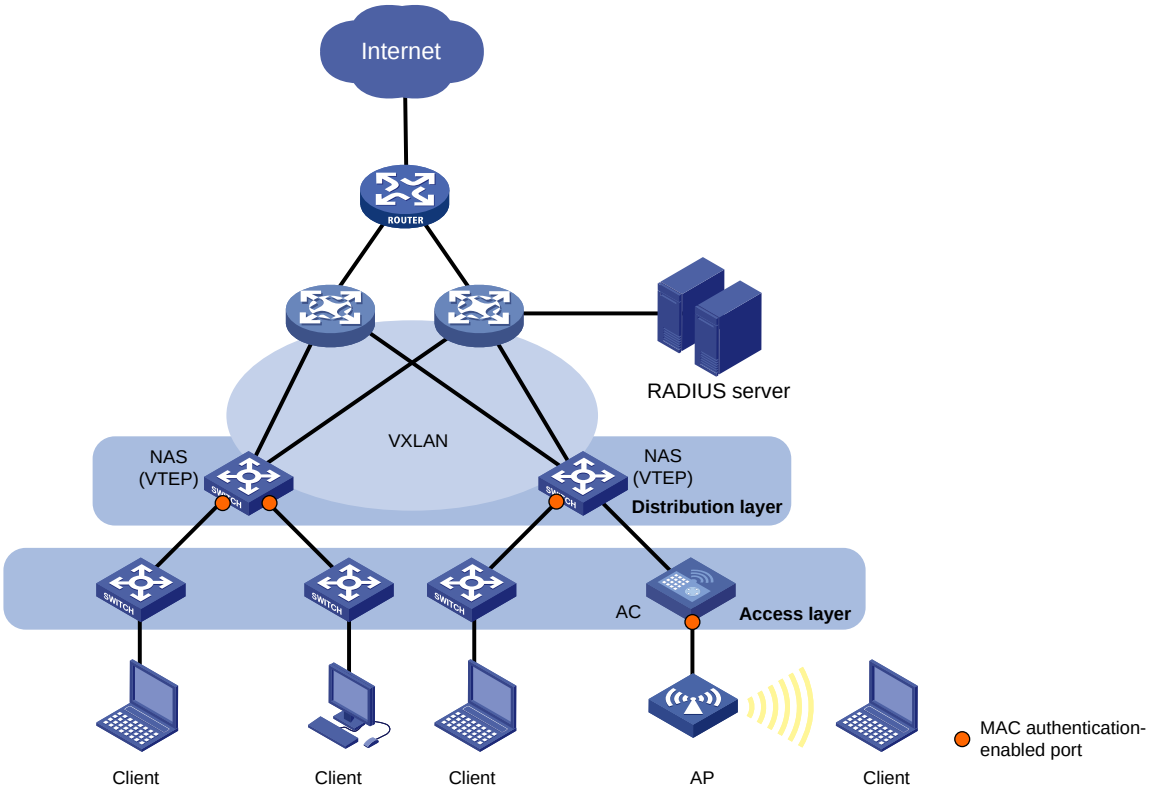
The MAC authentication critical VLAN on a port accommodates users that have failed MAC authentication because no RADIUS authentication servers are reachable. Users in a MAC authentication critical VLAN can access only network resources in the critical VLAN.

The critical VLAN feature takes effect when MAC authentication is performed only through RADIUS servers. If a MAC authentication user fails local authentication after RADIUS authentication, the user is not assigned to the critical VLAN. For more information about the authentication methods, see "Configuring AAA."

Table 4 shows the way that the network access device handles critical VLANs for MAC authentication users.

Table 4 VLAN manipulation

Authentication status	VLAN manipulation
A user fails MAC authentication because all the RADIUS servers are unreachable.	The device maps the MAC address of the user to the MAC authentication critical VLAN. The user is still in the MAC authentication critical VLAN if the user fails MAC reauthentication because all the RADIUS servers are unreachable. If no MAC authentication critical VLAN is configured, the device maps the MAC address of the user to the PVID of the port.
A user in the MAC authentication guest VLAN fails authentication because all the RADIUS servers are unreachable.	The user remains in the MAC authentication guest VLAN.
A user in the MAC authentication critical VLAN fails MAC authentication for any reason other than server unreachable.	If a guest VLAN has been configured, the device maps the MAC address of the user to the guest VLAN. If no guest VLAN is configured, the device maps the MAC address of the user to the PVID of the port.
A user in the MAC authentication critical VLAN passes MAC authentication.	The device remaps the MAC address of the user to the authorization VLAN assigned by the authentication server. If no authorization VLAN is configured for the user on the authentication server, the device remaps the MAC address of the user to the PVID of the access port.



VSI manipulation

MAC authentication support for VXLANs

As shown in Figure 4, when the device acts as both a VXLAN VTEP and a NAS, users' service information cannot be identified by VLANs. To resolve this issue, you must configure the RADIUS server to assign VSIs to MAC authenticated users. The NAS will map a user's traffic to the VXLAN that is associated with the user's authorization VSI. The mapping criteria include the user's access VLAN, access port, and MAC address.

For information about VSIs and VXLANs, see *VXLAN Configuration Guide*.

Figure 4 VXLAN network diagram for MAC authentication

Authorization VSI

An authorization VSI is associated with a VXLAN that has network resources inaccessible to unauthenticated users.

MAC authentication supports remote VSI authorization. If the VTEP does not receive authorization VSI information for a MAC authentication user from the remote server, the user cannot access resources in any VXLAN after passing authentication. If the VTEP receives authorization VSI information for the user from the remote server, it performs the following operations:

- Dynamically creates an Ethernet service instance according to the user's access port, VLAN, and MAC address.
- Maps the Ethernet service instance to the authorization VSI.

  The user then can access resources in the VXLAN associated with the authorization VSI.

For information about dynamic creation of Ethernet service instances, see *VXLAN configuration Guide*.

Guest VSI

The MAC authentication guest VSI on a port accommodates users that have failed MAC authentication for any reason other than server unreachable. For example, the VSI accommodates users with invalid passwords entered.

You can deploy a limited set of network resources in the VXLAN that is associated with the MAC authentication guest VSI. For example, a software server for downloading software and system patches.

Table 5 shows the way that the VTEP handles guest VSIs for MAC authentication users.

Table 5 VSI manipulation

Authentication status	VSI manipulation
A user fails MAC authentication for any reason other than server unreachable.	The VTEP maps the user's MAC address and access VLAN to the MAC authentication guest VSI.
A user in the MAC authentication guest VSI fails MAC authentication for any reason other than server unreachable.	The user is still in the MAC authentication guest VSI.
A user in the MAC authentication guest VSI passes MAC authentication.	The VTEP remaps the user's MAC address and access VLAN to the authorization VSI assigned by the authentication server.

Critical VSI

The MAC authentication critical VSI on a port accommodates users that have failed MAC authentication because no RADIUS authentication servers are reachable. Users in a MAC authentication critical VSI can access only network resources in the VXLAN associated with this VSI.

The critical VSI feature takes effect when MAC authentication is performed only through RADIUS servers. If a MAC authentication user fails local authentication after RADIUS authentication, the user is not assigned to the critical VSI. For more information about the authentication methods, see "Configuring AAA."

Table 6 shows the way that the VTEP handles critical VSIs for MAC authentication users.

Table 6 VSI manipulation

Authentication status	VSI manipulation
A user fails MAC authentication because all the RADIUS servers are unreachable.	The VTEP maps the user's MAC address and access VLAN to the MAC authentication critical VSI. The user is still in the MAC authentication critical VSI if the user fails MAC reauthentication because all the RADIUS servers are unreachable. If no MAC authentication critical VSI is configured, the device logs off the user.
A user in the MAC authentication critical VSI fails MAC authentication for any reason other than server unreachable.	If a guest VSI has been configured, the VTEP maps the user's MAC address and access VLAN to the guest VSI. If no guest VSI is configured, the VTEP logs off the user.
A user in the MAC authentication guest VSI fails authentication because all the RADIUS servers are unreachable.	The user remains in the MAC authentication guest VSI.

Authentication status	VSI manipulation
A user in the MAC authentication critical VSI passes MAC authentication.	The VTEP remaps the user's MAC address and access VLAN to the authorization VSI assigned by the authentication server.

Microsegment assignment

Authorization microsegment

The microsegmentation feature provides group-based traffic control by applying policy to groups of traffic that has same attributes. A microsegment is a group of traffic that matches the same criteria. The RADIUS server can assign a microsegment to a user after that user passes MAC authentication, Then, the device performs microsegment-based traffic filtering for that user on the user's access port to make sure the user can access only the network resources available for the microsegment.

For more information about microsegmentation, see "Configuring microsegmentation."

IMPORTANT:

The following restrictions apply to MAC authentication on a microsegmented network:

- The server must assign an authorization ACL, redirect URL, and microsegment to a MAC user if that user must pass Web authentication.
- If the server assigns both an authorization ACL and an authorization microsegment to a MAC authentication user that does not require Web authentication, only the authorization microsegment takes effect.

Critical microsegment

The MAC authentication critical microsegment on a port accommodates users that have failed MAC authentication because no RADIUS authentication servers are reachable. Users in a MAC authentication critical microsegment can access only network resources in the critical microsegment. The microsegment can belong to a VLAN or VXLAN.

The critical microsegment feature takes effect when MAC authentication is performed only through RADIUS servers. If a MAC authentication user fails local authentication after RADIUS authentication, the user is not assigned to the critical microsegment. For more information about the authentication methods, see "Configuring AAA."

The access device assigns or removes a MAC authentication user to or from the critical microsegment depending on their authentication status, as shown in Table 7.

Table 7 VSI manipulation

Authentication status	Microsegment manipulation
A user fails MAC authentication because all the RADIUS servers are unreachable.	The access device maps the MAC address of the user to the MAC authentication critical microsegment. The MAC address of the user is still in the MAC authentication critical microsegment if the user fails MAC reauthentication because all the RADIUS servers are unreachable.
A user in the MAC authentication critical microsegment fails MAC authentication for any reason other than server unreachable.	The access device removes the MAC address of the user from the MAC authentication critical microsegment.

Authentication status	Microsegment manipulation
A user in the MAC authentication critical microsegment passes MAC authentication.	The access device maps the MAC address of the user to the authorization microsegment assigned by the authentication server.

ACL assignment

You can specify an authorization ACL for a MAC authentication user on a remote server or the access device to control the user's access to network resources. After the user passes MAC authentication, the server or access device assigns the authorization ACL to the user access port. Then, the port permits or drops the matching traffic for the user depending on the rules in the ACL.

The device supports assignment of static and dynamic authorization ACLs.

- **Assignment of static authorization ACLs**—Static ACLs can be assigned by a RADIUS server or the access device. When the server or access device assigns a static ACL to a user, it assigns only the ACL number. You must manually create the ACL and configure its rules on the access device.

  To change the access permissions of a user, use one of the following methods:

  - Modify ACL rules in the authorization ACL on the access device.
  - Assign another ACL to the user as the authorization ACL from the RADIUS server or the access device.

  Static ACLs and their rules can be manually deleted from the access device.
- **Assignment of dynamic authorization ACLs**—Dynamic ACLs and their rules are automatically deployed by a RADIUS server, which are not configurable on the access device. Dynamic ACLs can only be named ACLs. After the device receives a server-deployed dynamic ACL and its rules, it automatically creates the ACL and configures its rules.

  If a dynamic ACL assigned by the server to a user has the same name as a static ACL, the dynamic ACL cannot be issued and the user cannot come online.

  A dynamic ACL and its rules are automatically deleted from the access device after all its users go offline.

  Dynamic ACLs and their rules cannot be manually modified or deleted on the access device. To display information about dynamic ACLs and their rules, use the **`display mac-authentication connection`** or **`display acl`** command.

IMPORTANT:

The supported authorization ACLs include the following types:

- Basic ACLs, which are numbered in the range of 2000 to 2999.
- Advanced ACLs, which are numbered in the range of 3000 to 3999.
- Layer 2 ACLs, which are numbered in the range of 4000 to 4999.
- User-defined ACLs, which are numbered in the range of 5000 to 5999.

For an authorization ACL to take effect, make sure the ACL exists with rules and none of the rules contains the **`counting`**, **`established`**, **`fragment`**, **`source-mac`**, **`cos`**, **`dest-mac`**, **`lsap`**, or **`logging`** keyword.

For more information about ACLs, see *ACL and QoS Command Reference*.

IMPORTANT:

If the server assigns both an authorization ACL and microsegment to a MAC authentication user on a microsegmented network, only the authorization microsegment takes effect.

Redirect URL assignment

The device supports the URL attribute assigned by a RADIUS server. During MAC authentication, the HTTP or HTTPS requests of a user are redirected to the Web interface specified by the server-assigned URL attribute. After the user passes the Web authentication, the RADIUS server records the MAC address of the MAC authentication user and uses a DM (Disconnect Message) to log off the user. When the user initiates MAC authentication again, it will pass the authentication and come online successfully.

By default, the device listens to port 6654 for HTTPS requests to be redirected. To change the redirect listening port number, see configuring HTTP redirect in *Layer 3—IP Services Configuration Guide*.

Blackhole MAC attribute assignment

The device supports the blackhole MAC attribute assigned by the RADIUS authentication server through CoA messages for users that have passed MAC authentication. Upon receiving a CoA message that contains the blackhole MAC attribute for a user that has passed MAC authentication, the device performs the following operations:

1. Logs off the user.
2. Marks the MAC address of the user as a silent MAC address and starts a quiet timer for the MAC address.

The quiet timer is 10 minutes and is not user configurable. The device drops all packets from the MAC address after the quiet timer starts, and it will not authenticate the MAC address until the quiet timer expires.

To display silent MAC addresses, use the **`display mac-authentication`** command.

Periodic MAC reauthentication

Periodic MAC reauthentication tracks the connection status of online users, and updates the authorization attributes assigned by the RADIUS server. The attributes include the ACL and VLAN.

The device reauthenticates online MAC authentication users at the periodic reauthentication interval when the periodic MAC reauthentication feature is enabled. The interval is controlled by a timer and the timer is user configurable. A change to the periodic reauthentication timer applies to online MAC authentication users only after the old timer expires and the MAC authentication users pass authentication.

The server-assigned RADIUS Session-Timeout (attribute 27) and Termination-Action (attribute 29) attributes together can affect the periodic MAC reauthentication feature. To display the server-assigned Session-Timeout and Termination-Action attributes, use the **`display mac-authentication connection`** command.

- If the termination action is to log off users, periodic MAC reauthentication takes effect only when the periodic reauthentication timer is shorter than the session timeout timer. If the session timeout timer is shorter, the device logs off online authenticated users when the session timeout timer expires.
- If the termination action is to reauthenticate users, the periodic MAC reauthentication configuration on the device cannot take effect. The device reauthenticates online MAC authentication users after the server-assigned session timeout timer expires.

If no session timeout timer is assigned by the server, whether the device performs periodic MAC reauthentication depends on the periodic MAC reauthentication configuration on the device. Support for the assignment of Session-Timeout and Termination-Action attributes depends on the server model.

With the RADIUS DAS feature enabled, the device immediately reauthenticates a user upon receiving a CoA message that carries the reauthentication attribute from a RADIUS authentication server. In this case, reauthentication will be performed regardless of whether periodic MAC reauthentication is enabled on the device. For more information about RADIUS DAS configuration, see "Configuring AAA."

By default, the device logs off online MAC authentication users if no server is reachable for MAC reauthentication. The keep-online feature keeps authenticated MAC authentication users online when no server is reachable for MAC reauthentication.

The VLANs assigned to an online user before and after reauthentication can be the same or different.

RESTful server-assisted MAC authentication user recovery

Applicable scenario

After online dumb terminals such as printers go offline, they cannot reauthenticate to come online until after they send a service packet. This might cause the dumb terminals to stay offline for a long time after the device or their attached interface module reboots or after their attached interfaces fail.

To avoid this situation, you can configure the device to work with the authentication server and a RESTful server to trigger MAC reauthentication for dumb terminals or retain their online state.

NOTE:

This feature is available only when you use IMC server as the authentication server and the RESTful server.

Operating mechanism

The following information describes how RESTful server-assisted MAC authentication user recovery works:

1. The authentication server includes the **shutdown-keep-online** proprietary attribute in the authorization attributes assigned to a dumb terminal after it passes authentication.
2. After receiving the authentication result from the authentication server, the device allows the dumb terminal user to come online and marks it as a dumb terminal user.
3. When a device or interface issue occurs, the device handles the dumb terminal user as follows:
   - If the device or the interface module reboots or if the interface recovers from a failure, the device obtains MAC authentication user information from the RESTful server to perform MAC reauthentication.
   - If the interface is physical down, the device retains the online state of the dumb terminal user.

Restrictions and guidelines: MAC authentication configuration

When you configure MAC authentication on an interface, follow these restrictions and guidelines:

- MAC authentication is supported only on Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces.

- If you add a Layer 2 Ethernet interface to an aggregation group, the MAC authentication settings configured on it will not take effect until it is removed from the aggregation group.
- Do not delete a Layer 2 aggregate interface if the interface has online MAC authentication users.
- Do not change the link type of a port when the MAC authentication guest VLAN or critical VLAN on the port has users.

When you configure MAC authentication VLANs or VSIs, follow these restrictions and guidelines:

- If the server assigns both an authorization VSI and authorization VLAN to a user, the device uses only the authorization VLAN.
- On a port, the following MAC authentication settings are mutually exclusive:
  - Guest and critical VLAN settings.
  - Guest and critical VSI settings.
  - Critical microsegment settings.
- On a port, the MAC authentication guest and critical VLAN settings are mutually exclusive with the 802.1X guest, Auth-Fail, and critical VSI settings.
- On a port, the MAC authentication guest and critical VSI settings are mutually exclusive with the 802.1X guest, Auth-Fail, and critical VLAN settings.
- To ensure a successful authentication, you must configure the authentication server to assign authorization VLANs or VSIs to the MAC authentication users attached to a port in the following situations:
  - If the MAC authentication-enabled port is configured with the guest VLAN or critical VLAN, configure the authentication server to assign authorization VLANs to MAC authentication users.
  - If the MAC authentication-enabled port is configured with the guest VSI or critical VSI, configure the authentication server to assign authorization VSIs to MAC authentication users.
  - If both 802.1X and MAC authentication are configured on the port, be careful with the VSI settings of the two authentication features.
    - You must configure VSI authorization for the MAC authentication users if the port has an Auth-Fail, guest, or critical VSI for 802.1X authentication.
    - Likewise, you must configure VSI authorization for the 802.1X users if the port has a guest or critical VSI for MAC authentication.
- As a best practice, do not use Web authentication in conjunction with any of the following MAC authentication settings on a port:
  - Guest VLAN and critical VLAN settings.
  - Guest VSI and critical VSI settings.
  - Critical microsegment settings.
- As a best practice, do not use port security preauthentication domain in conjunction with any of the following MAC authentication settings on a port:
  - Guest VLAN and critical VLAN settings.
  - Guest VSI and critical VSI settings.
  - Critical microsegment settings.
  - Critical profile settings.

If the MAC address that has failed authentication is a static MAC address or a MAC address that has passed any security authentication, the device does not mark the MAC address as a silent address.

To ensure a successful HTTPS redirect for users who have received a server-assigned redirect URL, make sure VLAN interfaces or VSI interfaces exist for the VLANs or VSIs that transport their packets, respectively.

When RADIUS DAS is enabled, an M-LAG system does not support shutting down or rebooting the access ports of MAC authentication users or reauthenticating the users through CoA messages. For more information about RADIUS DAS, see "Configuring AAA."

MAC authentication tasks at a glance

To configure MAC authentication, perform the following tasks:

1. Enabling MAC authentication
2. Configure basic MAC authentication features
   - Specifying a MAC authentication method
   - Specifying a MAC authentication domain
   - Configuring user account policy
   - (Optional.) Configuring MAC authentication timers
   - (Optional.) Configuring periodic MAC reauthentication
3. (Optional.) Configuring MAC authentication VLAN assignment
   - Configuring a MAC authentication guest VLAN
   - Configuring a MAC authentication critical VLAN
4. (Optional.) Configuring MAC authentication VSI assignment
   - Configuring a MAC authentication guest VSI
   - Configuring a MAC authentication critical VSI
5. (Optional.) Configuring a MAC authentication critical microsegment
6. (Optional.) Configuring a MAC authentication access profile
7. (Optional.) Configuring other MAC authentication features
   - Configuring a MAC authentication critical microsegment
   - Configuring unauthenticated MAC authentication user aging
   - Configuring MAC authentication offline detection
   - Enabling online MAC authentication users to escape from offline detection and stay online when no reachable RADIUS authentication servers are available
   - Enabling online user synchronization for MAC authentication
   - Setting the maximum number of concurrent MAC authentication users on a port
   - Enabling MAC authentication multi-VLAN mode on a port

     Perform this task to not reauthenticate online users when VLAN changes occur on a port.
   - Configuring MAC authentication delay
   - Including user IP addresses in MAC authentication requests
   - Enabling parallel MAC authentication and 802.1X authentication
   - Configuring RESTful server-assisted MAC authentication user recovery
   - Tracking the availability of the Web authentication server at a redirect URL
   - Configuring Web proxy ports for URL redirection in MAC authentication
   - Logging off MAC authentication users
   - Enabling MAC authentication user logging

Prerequisites for MAC authentication

Before you configure MAC authentication, complete the following tasks:

1. Make sure the port security feature is disabled. For more information about port security, see "Configuring port security."
2. Configure an ISP domain and specify an AAA method. For more information, see "Configuring AAA."
   - For local authentication, you must also create local user accounts (including usernames and passwords) and specify the **lan-access** service for local users.
   - For RADIUS authentication, make sure the device and the RADIUS server can reach each other and create user accounts on the RADIUS server. If you are using MAC-based accounts, make sure the username and password for each account are the same as the MAC address of each MAC authentication user.

Enabling MAC authentication

Restrictions and guidelines

For MAC authentication to take effect on a port, you must enable this feature globally and on the port.

MAC authentication cannnot take effect on a port if the device has run out of ACL resources when you perform either of the following operations:

- Enable MAC authentication on the port while MAC authentication has been enabled globally.
- Enable MAC authentication globally in system while MAC authentication has been enabled on the port.

Procedure

1. Enter system view.
   `system-view`
2. Enable MAC authentication globally.
   `mac-authentication`
   By default, MAC authentication is disabled globally.
3. Enter interface view.
   `interface` *`interface-type interface-number`*
4. Enable MAC authentication on the port.
   `mac-authentication`
   By default, MAC authentication is disabled on a port.

Specifying a MAC authentication method

About this task

RADIUS-based MAC authentication supports the following authentication methods:

- **PAP**—Transports usernames and passwords in plain text. The authentication method applies to scenarios that do not require high security.
- **CHAP**—Transports usernames in plain text and passwords in encrypted form over the network. CHAP is more secure than PAP.

Restrictions and guidelines

The device must use the same authentication method as the RADIUS server.

Procedure

1. Enter system view.
   `system-view`

2. Specify an authentication method for MAC authentication.

   mac-authentication authentication-method { **chap** | **pap** }

   By default, the device uses PAP for MAC authentication.

Specifying a MAC authentication domain

About this task

By default, MAC authentication users are in the system default authentication domain. To implement different access policies for users, you can use one of the following methods to specify authentication domains for MAC authentication users:

- Specify a global authentication domain in system view. This domain setting applies to all ports enabled with MAC authentication.
- Specify an authentication domain for an individual port in interface view.

MAC authentication chooses an authentication domain for users on a port in this order: the port-specific domain, the global domain, and the default domain. For more information about authentication domains, see "Configuring AAA."

Procedure

1. Enter system view.

   system-view

2. Specify an authentication domain for MAC authentication users.
   - In system view:

     mac-authentication domain *domain-name*
   - In interface view:

     interface *interface-type interface-number*

     mac-authentication domain *domain-name*

   By default, the system default authentication domain is used for MAC authentication users.

Configuring user account policy

Restrictions and guidelines

For users in a MAC address range, the MAC address range-specific user account has higher priority than the global user account settings.

You can configure a maximum of 16 MAC address ranges and must make sure the MAC address ranges do not overlap.

If you configure user account settings multiple times for the same MAC address range, the most recent configuration overwrites the previous configuration.

The MAC range-specific accounts apply only to unicast MAC addresses.

- If you specify a MAC address range that contains only multicast MAC addresses, execution of this command will fail.
- If you specify a MAC address range that contains both unicast and multicast MAC addresses, the command takes effect only on unicast MAC addresses.

The all-zero MAC address is invalid for MAC authentication. Users with the all-zero MAC address cannot pass MAC authentication.

Procedure

1. Enter system view.

system-view

2. Configure the global MAC authentication user account policy.
   - Use one MAC-based user account for each user.

     mac-authentication user-name-format mac-address [{ **with-hyphen** [**separator colon**] | **without-hyphen** } [**lowercase** | **uppercase**]] [**password** { **cipher** | **simple** } *string*]
   - Use one shared user account for all users.

     mac-authentication user-name-format fixed [**account** *name*] [**password** { **cipher** | **simple** } *string*]

   By default, the device uses the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation without hyphens, and letters are in lower case.
3. Specify one shared user account specific to a MAC address range.

   mac-authentication mac-range-account mac-address *mac-address* **mask** { *mask* | *mask-length* } **account** *name* **password** { **cipher** | **simple** } *string*

   By default, no username or password is configured specific to a MAC address range. The global user account policy applies to the users.

Configuring MAC authentication timers

About this task

MAC authentication uses the following timers:

- **Offline detection timer**—Sets the interval that the device must wait for traffic from a user before the device determines that the user is idle. If the device has not received traffic from a user before the timer expires, the device logs off that user and requests the accounting server to stop accounting for the user. This timer takes effect only when the MAC authentication offline detection feature is enabled.

  As a best practice, set the MAC address aging timer to the same value as the offline detection timer. This operation prevents a MAC authenticated user from being logged off within the offline detection interval because of MAC address entry expiration.
- **Quiet timer**—Sets the interval that the device must wait before the device can perform MAC authentication for a user that has failed MAC authentication. All packets from the MAC address are dropped during the quiet time. This quiet mechanism prevents repeated authentication from affecting system performance.
- **Server timeout timer**—Sets the interval that the device waits for a response from a RADIUS server before the device determines that the RADIUS server is unavailable. If the timer expires during MAC authentication, the user fails MAC authentication.
- **Aging timer for temporary MAC authentication users**—Sets the aging timer for temporary MAC authentication users. This timer starts when a user passes MAC authentication on a port operating in **macAddressAndUserLoginSecureExt** mode. If the device has not received 802.1X protocol packets from the MAC authenticated user on that port before the timer expires, the device determines that the user has failed authentication. Then, the device logs off the user. For more information about the port security mode, see "Configuring port security."

Restrictions and guidelines

To avoid forced logoff before the server timeout timer expires, set the server timeout timer to a value that is lower than or equal to the product of the following values:

- The maximum number of RADIUS packet transmission attempts set by using the **retry** command in RADIUS scheme view.

- The RADIUS server response timeout timer set by using the **timer response-timeout** command in RADIUS scheme view.

For information about setting the maximum number of RADIUS packet transmission attempts and the RADIUS server response timeout timer, see "Configuring AAA."

Procedure

1. Enter system view.

   system-view

2. Configure MAC authentication timers.

   mac-authentication timer { **offline-detect** *offline-detect-value* | **quiet** *quiet-value* | **server-timeout** *server-timeout-value* | **temporary-user-aging** *aging-time-value* }

   The default settings are as follows:

   - The offline detection timer is 300 seconds.
   - The quiet timer is 60 seconds.
   - The server timeout timer is 100 seconds.
   - The temporary user aging timer is 60 seconds.

Configuring periodic MAC reauthentication

Restrictions and guidelines

The device selects a periodic reauthentication timer for MAC reauthentication in the following order:

1. Server-assigned reauthentication timer.
2. Port-specific reauthentication timer.
3. Global reauthentication timer.
4. Default reauthentication timer.

Modification to the MAC authentication domain, MAC authentication method, or user account format setting does not affect the reauthentication of online MAC authentication users. The modified setting takes effect only on MAC authentication users that come online after the modification.

If periodic reauthentication is triggered for a user while that user is waiting for online synchronization, the system performs online synchronization and does not perform reauthentication for the user.

Procedure

1. Enter system view.

   system-view

2. Set the periodic MAC reauthentication timer.

   - Set a global periodic reauthentication timer.

     mac-authentication timer reauth-period *reauth-period-value*

     The default setting is 3600 seconds.

   - Execute the following commands in sequence to set a port-specific periodic reauthentication timer:

     interface *interface-type interface-number*

     mac-authentication timer reauth-period *reauth-period-value*

     quit

     By default, no periodic MAC reauthentication timer is set on a port. The port uses the global periodic MAC reauthentication timer.

3. Enter interface view.

interface *interface-type interface-number*

4. Enable periodic MAC reauthentication.

   mac-authentication re-authenticate

   By default, periodic MAC reauthentication is disabled on a port.

5. (Optional.) Enable the keep-online feature for MAC authenticated users on the port.

   mac-authentication re-authenticate server-unreachable keep-online

   By default, the keep-online feature is disabled. The device logs off online MAC authentication users if no server is reachable for MAC reauthentication.

   In a fast-recovery network, you can use the keep-online feature to prevent MAC authentication users from coming online and going offline frequently.

Configuring a MAC authentication guest VLAN

Specifying a MAC authentication guest VLAN on a port

Restrictions and guidelines

When you configure the MAC authentication guest VLAN on a port, follow the guidelines in Table 8.

Table 8 Relationships of the MAC authentication guest VLAN with other security features

Feature	Relationship description	Reference
Quiet feature of MAC authentication	The MAC authentication guest VLAN feature has higher priority. When a user fails MAC authentication, the user can access the resources in the guest VLAN. The user's MAC address is not marked as a silent MAC address.	See "Configuring MAC authentication timers."
Port intrusion protection	The guest VLAN feature has higher priority than the block MAC action but lower priority than the shutdown port action of the port intrusion protection feature.	See "Configuring port security."

Prerequisites

Before you configure the MAC authentication guest VLAN on a port, complete the following tasks:

- Create the VLAN to be specified as the MAC authentication guest VLAN.
- Configure the port as a hybrid port, and configure the VLAN as an untagged member on the port.
- Enable MAC-based VLAN on the port.

For information about VLAN configuration, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify the MAC authentication guest VLAN on the port.

   mac-authentication guest-vlan *guest-vlan-id*

   By default, no MAC authentication guest VLAN is specified on a port.

You can configure only one MAC authentication guest VLAN on a port. The MAC authentication guest VLANs on different ports can be different.

Enabling guest VLAN reauthentication in MAC authentication

About this task

The guest VLAN reauthentication feature of MAC authentication enables the device to reauthenticate users in the MAC authentication guest VLAN on a port at reauthentication intervals.

By default, this feature is enabled. You can disable it as needed to suppress excessive authentication failure log messages, which might occur when a network issue results in a large number of reauthentication failures.

If guest VLAN reauthentication is disabled on a port, the device does not reauthenticate users in the MAC authentication guest VLAN on the port. The guest VLAN users will stay in the guest VLAN until they age out. To control guest VLAN user aging functionality, use the **mac-authentication unauthenticated-user aging enable** command. To configure the aging timer, use the **mac-authentication timer user-aging guest-vlan** *aging-time-value* command.

Restrictions and guidelines

As a best practice, set the reauthentication interval to a value greater than 30 seconds if the number of concurrent MAC authentication users on a port is likely to exceed 300.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the guest VLAN reauthentication feature of MAC authentication on the port.
   mac-authentication guest-vlan re-authenticate
   By default, the guest VLAN reauthentication feature of MAC authentication is enabled on a port.
4. Set the authentication interval for users in the MAC authentication guest VLAN.
   mac-authentication guest-vlan auth-period *period-value*
   The default setting is 30 seconds.

Configuring a MAC authentication critical VLAN

Restrictions and guidelines

When you configure the MAC authentication critical VLAN on a port, follow the guidelines in Table 9.

Table 9 Relationships of the MAC authentication critical VLAN with other security features

Feature	Relationship description	Reference
Quiet feature of MAC authentication	The MAC authentication critical VLAN feature has higher priority. When a user fails MAC authentication because no RADIUS authentication server is reachable, the user can access the resources in the critical VLAN. The user's MAC address is not marked as a silent MAC address.	See "Configuring MAC authentication timers."
Port intrusion protection	The critical VLAN feature has higher priority than the block MAC action but lower priority than the	See "Configuring port security."

Feature	Relationship description	Reference
	shutdown port action of the port intrusion protection feature.	

Prerequisites

Before you configure the MAC authentication critical VLAN on a port, complete the following tasks:

- Create the VLAN to be specified as the MAC authentication critical VLAN.
- Configure the port as a hybrid port, and configure the VLAN as an untagged member on the port.
- Enable MAC-based VLAN on the port.

For information about VLAN configuration, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Specify the MAC authentication critical VLAN on the port.

   mac-authentication critical vlan *critical-vlan-id* [**url-user-logoff**]

   By default, no MAC authentication critical VLAN is specified on a port.

   You can configure only one MAC authentication critical VLAN on a port. The MAC authentication critical VLANs on different ports can be different.

Configuring a MAC authentication guest VSI

Specifying a MAC authentication guest VSI on a port

Restrictions and guidelines

The MAC authentication guest VSI feature has higher priority than the quiet feature of MAC authentication. When a user fails MAC authentication, the user can access the resources in the guest VSI. The user's MAC address is not marked as a silent MAC address.

You can configure only one MAC authentication guest VSI on a port. The MAC authentication guest VSIs on different ports can be different.

Prerequisites

To ensure that the MAC authentication guest VSI on a port can take effect, complete the following tasks:

- Enable L2VPN.
- Create the VSI to be specified as the MAC authentication guest VSI, and create a VXLAN for the VSI.
- Enable MAC-based traffic match mode for dynamic Ethernet service instances on the port.

For more information, see *VXLAN Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the MAC authentication guest VSI on the port.
   mac-authentication guest-vsi *guest-vsi-name*
   By default, no MAC authentication guest VSI exists on a port.

Enabling guest VSI reauthentication in MAC authentication

About this task

The guest VSI reauthentication feature of MAC authentication enables the device to reauthenticate users in the MAC authentication guest VSI on a port at reauthentication intervals.

You can enable guest VSI reauthentication by using the **mac-authentication guest-vsi re-authenticate** command or disable the feature by using the **undo** form of the command.

Typically, you disable this feature to suppress excessive authentication failure log messages, which might occur when a network issue results in a large number of reauthentication failures.

If guest VSI reauthentication is disabled on a port, the device does not reauthenticate users in the MAC authentication guest VSI on the port. The guest VSI users will stay in the guest VSI until they age out. To configure the aging timer, use the **mac-authentication timer user-aging guest-vsi** *aging-time-value* command.

Restrictions and guidelines

As a best practice, set the reauthentication interval to a value greater than 30 seconds if the number of concurrent MAC authentication users on a port is likely to exceed 300.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the guest VSI reauthentication feature of MAC authentication on the port.
   mac-authentication guest-vsi re-authenticate
   By default, the guest VSI reauthentication feature of MAC authentication is enabled on a port.
4. Set the authentication interval for users in the MAC authentication guest VSI.
   mac-authentication guest-vsi auth-period *period-value*
   The default setting is 30 seconds.

Configuring a MAC authentication critical VSI

Restrictions and guidelines

The MAC authentication critical VSI feature has higher priority than the quiet feature of MAC authentication. When a user fails MAC authentication, the user can access the resources in the critical VSI. The user's MAC address is not marked as a silent MAC address.

You can configure only one MAC authentication critical VSI on a port. The MAC authentication critical VSIs on different ports can be different.

Prerequisites

To ensure that the MAC authentication critical VSI on a port can take effect, complete the following tasks:

- Enable L2VPN.
- Create the VSI to be specified as the MAC authentication critical VSI, and create a VXLAN for the VSI.
- Enable MAC-based traffic match mode for dynamic Ethernet service instances on the port.

For more information, see *VXLAN Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the MAC authentication critical VSI on the port.
   mac-authentication critical vsi *critical-vsi-name* [**url-user-logoff**]
   By default, no MAC authentication critical VSI exists on a port.

Specifying a critical profile for MAC authentication users on a port

About this task

A critical profile specifies a limited set of resources accessible to MAC authentication users when they cannot get authenticated because none of the applicable RADIUS servers is available.

To make sure the MAC authentication users attached to a port can access the resources in a critical profile in the server unavailable situation, perform this task.

Restrictions and guidelines

You can specify only one critical profile for MAC authentication on a port. The critical profiles for MAC authentication on different ports can be different.

On an interface, the critical profile settings are mutually exclusive with the critical VSI, critical VLAN, and critical microsegment settings for MAC authentication.

For more information, see the command reference and "Restrictions and guidelines: MAC authentication configuration."

Prerequisites

As a best practice, configure the critical profile before you perform this task. For more information about configuring critical profiles, see "Configuring AAA."

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify a critical profile for MAC authentication users on the port.
   mac-authentication critical profile *profile-name*
   By default, no critical profile is specified for MAC authentication users on a port.

Configuring a MAC authentication critical microsegment

Restrictions and guidelines

The MAC authentication critical microsegment feature has higher priority than the MAC authentication quiet feature. If the device adds a MAC address to a critical microsegment, it will not add that MAC address to the quiet MAC address list.

You can configure only one MAC authentication critical microsegment on a port. The MAC authentication critical microsegments on different ports can be the same or different.

Prerequisites

For the critical microsegment you specify for MAC authentication on a port to take effect, you must create that microsegment. For more information about microsegments, see "Configuring microsegmentation."

To specify a VSI to match user packets in VSIs, perform the following tasks:

- Enable L2VPN.
- Enable MAC-based traffic match mode for dynamic Ethernet service instances on the port.

For more information, see *VXLAN Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Specify the MAC authentication critical microsegment on the port.

   mac-authentication critical microsegment *microsegment-id* [**vsi** *vsi-name*] [**url-user-logoff**]

   By default, no MAC authentication critical microsegment is configured on a port.

Configuring a MAC authentication access profile

About this task

The device uses MAC authentication access profiles to uniformly manage configurations related to MAC authentication access. After you bind a MAC authentication access profile to a port security authentication profile, the interface bound to the port security authentication profile will use the access profile's configuration to authenticate users.

After you bind a port security authentication profile to an interface:

- For settings that can be configured both in interface view and MAC authentication access profile view (the command lines might differ in the views), the system automatically deletes the settings in interface view regardless of whether the port security authentication profile has been bound to a MAC authentication access profile. To use these settings, configure them in the MAC authentication access profile bound to the port security authentication profile.
- For settings supported in interface view but not in MAC authentication access profile view, the settings in interface view still take effect.

For more information about port security authentication profiles, see "Configuring port security."

Restrictions and guidelines

If a MAC authentication access profile bound to a port security authentication profile has taken effect, deleting the access profile will cause users who have come online using this access profile to disconnect abnormally.

A MAC authentication access profile can be bound to multiple port security authentication profiles, but a port security authentication profile can be bound to only one MAC authentication access profile. To bind another MAC authentication access profile to a port security authentication profile, you must first unbind the existing one.

Procedure

1. Enter system view.

   system-view

2. Create a MAC authentication access profile and enter its view.

   mac-authentication access-profile name *profile-name*

   By default, no MAC authentication access profiles exist.

3. Configure supported MAC authentication features as needed.

   Only some MAC authentication features are supported in MAC authentication access profile view. For more information, see the command reference.

4. Enter a port security authentication profile view.

   port-security authentication-profile name *profile-name*

5. Bind the MAC authentication access profile to the port security authentication profile.

   mac-authentication access-profile *profile-name*

   By default, no MAC authentication access profile is bound to the port security authentication profile.

Configuring unauthenticated MAC authentication user aging

About this task

Unauthenticated MAC authentication user aging applies to users added to the following locations because they have not been authenticated or have failed authentication:

- MAC authentication guest or critical VLANs.
- MAC authentication guest or critical VSIs.
- MAC authentication critical microsegments.

When a user in one of those locations ages out, the device removes the user from the location and deletes the MAC address entry for the user from the access port.

For users in one of those locations on one port to be authenticated successfully and come online on another port, enable this feature. In any other scenarios, disable this feature as a best practice.

Restrictions and guidelines

Users removed from an access control segment upon aging timer expiration will be unable to access the network resources for that segment until after another authentication is triggered. As a best practice, use this feature on a port only if you want to have its unauthenticated users to be authenticated and come online on a different port.

Procedure

1. Enter system view.

   system-view

2. Set the user aging timer for a type of MAC authentication VLAN, VSI, or microsegment.

   mac-authentication timer user-aging { **critical-microsegment** | **critical-vlan** | **critical-vsi** | **guest-vlan** | **guest-vsi** } *aging-time-value*

   By default, the user aging timer is 1000 seconds for all applicable types of MAC authentication VLANs, VSIs, and microsegments.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable unauthenticated MAC authentication user aging.

   mac-authentication unauthenticated-user aging enable

   By default, unauthenticated MAC authentication user aging is enabled.

Configuring MAC authentication offline detection

About this task

Enable MAC authentication offline detection to detect idle users on a port. If the port has not received traffic from a user when the offline detection timer expires, the device logs off that user and requests the accounting server to stop accounting for the users. For information about setting the offline detection timer in system view, see "Configuring MAC authentication timers."

Disabling this feature disables the device from inspecting the online user status.

In addition to port-based MAC authentication offline detection, you can configure offline detection parameters on a per-user basis, as follows:

- Set an offline detection timer specific to a user and control whether to use the ARP snooping or ND snooping table to determine the offline state of the user.
  - If the ARP snooping or ND snooping table is used, the device searches the ARP snooping or ND snooping table before it checks for traffic from the user within the detection interval. If a matching ARP snooping or ND snooping entry is found, the device resets the offline detection timer and the user stays online. If the offline detection timer expires because the device has not found a matching snooping entry for the user or received traffic from the user, the device disconnects the user.
  - If the ARP or ND snooping table is not used, the device disconnects the user if it has not received traffic from that user before the offline detection timer expires.

  When disconnecting the user, the device also notifies the RADIUS server (if any) to stop user accounting.
- Skip offline detection for the user. You can choose this option if the user is a dumb terminal. A dumb terminal might fail to come online again after it is logged off by the offline detection feature.

The device uses the offline detection settings for a user in the following sequence:

1. User-specific offline detection settings.
2. Offline detection settings assigned to the user by the RADIUS server. The settings include the offline detection timer, use of the ARP or ND snooping table in offline detection, and whether to ignore offline detection.
3. Port-based offline detection settings.

MAC authentication offline detection takes effect on both of the following types of users:

- Users in preauthentication domains, authentication domains, critical domains, and Auth-Fail domains.

- Users assigned to guest VLANs or VSIs, Auth-Fail VLANs or VSIs, and critical VLANs, VSIs, or microsegments.

Restrictions and guidelines

For the user-specific offline detection feature to take effect on a user, make sure the MAC authentication offline detection feature is enabled on the user's access port.

The user-specific offline detection settings take effect on the online users immediately after they are configured.

If you enable MAC authentication offline detection on a Layer 2 aggregate interface, delay exists for the device to log off an idle user.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Configure MAC authentication offline detection for a user.

   mac-authentication offline-detect mac-address *mac-address* { **ignore** | **timer** *offline-detect-value* [**check-arp-or-nd-snooping**] }

   By default, offline detection settings configured on access ports take effect and the offline detection timer set in system view is used.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable MAC authentication offline detection.

   mac-authentication offline-detect enable

   By default, MAC authentication offline detection is enabled on a port.

Enabling online MAC authentication users to escape from offline detection and stay online when no reachable RADIUS authentication servers are available

About this task

The offline detection feature for MAC authentication logs off an online MAC authentication user if it has not detected traffic from that user before the offline-detect timer expires. To prevent online MAC authentication users on a port from being forced offline by the offline detection feature and stay online when none of the RADIUS servers in their ISP domain is reachable, perform this task.

Restrictions and guidelines

Use this feature only when RADIUS scheme authentication is configured for the MAC authentication users on a port. If local or no authentication is also configured, offline detection might be undesirably disabled for MAC authentication users that come online through local authentication or without authentication.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable online MAC authentication users to escape from offline detection and stay online when no reachable RADIUS authentication servers are available.

   mac-authentication auth-server-unavailable escape

   By default, online MAC authentication users cannot escape from offline detection (if enabled) when no reachable RADIUS authentication servers are available.

Enabling online user synchronization for MAC authentication

About this task

IMPORTANT:

This feature takes effect only when the device uses an IMC RADIUS server to authenticate MAC authentication users.

To ensure that the RADIUS server maintains the same online MAC authentication user information as the device after the server state changes from unreachable to reachable, use this feature.

This feature synchronizes online MAC authentication user information between the device and the RADIUS server when the RADIUS server state is detected having changed from unreachable to reachable.

When synchronizing online MAC authentication user information on a port with the RADIUS server, the device initiates MAC authentication in turn for each authenticated online MAC authentication user to the RADIUS server.

If synchronization fails for an online user, the device logs off that user unless the failure occurs because the server has become unreachable again.

Restrictions and guidelines

The amount of time required to complete online user synchronization increases as the number of online users grows. This might result in an increased delay for new MAC authentication users and users in the critical VLAN or VSI to authenticate or reauthenticate to the RADIUS server and come online.

To have this feature take effect, you must use it in conjunction with the RADIUS server status detection feature, which is configurable with the **radius-server test-profile** command. For more information about the RADIUS server status detection feature, see "Configuring AAA."

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable online user synchronization for MAC authentication.

   mac-authentication server-recovery online-user-sync

   By default, online user synchronization for MAC authentication is disabled.

Setting the maximum number of concurrent MAC authentication users on a port

About this task

Perform this task to prevent the system resources from being overused.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Set the maximum number of concurrent MAC authentication users on the port.

   mac-authentication max-user [**preauth-domain** | **auth-fail-domain**] *max-number*

   The default setting is 4294967295.

Enabling MAC authentication multi-VLAN mode on a port

About this task

By default, MAC authentication single-VLAN mode applies on a port. In this mode, traffic from an online user cannot be sent in different VLANs on a port without service interruption. To accommodate applications that are sensitive to delay or service interruption in a multi-VLAN environment, for example, IP phones, enable MAC authentication multi-VLAN mode.

In multi-VLAN mode, the port forwards traffic from a user in different VLANs without reauthentication if the user has been authenticated and come online in any VLAN on the port. Free of reauthentication, traffic from an online user can be sent in different VLANs without delay or service interruption.

In single-VLAN mode, the port reauthenticates an online user when traffic received from that user contains a VLAN tag different from the VLAN in which the user was authenticated. The authentication process differs depending on the MAC move setting in port security and the authorization VLAN assignment status, as follows:

- If no authorization VLAN has been assigned to the online user, the device first logs off the user and then reauthenticates the user in the new VLAN.
- If the online user has been assigned an authorization VLAN, the device handles the user depending on the MAC move setting in port security.
  - If MAC move is disabled in port security, the user cannot pass authentication and come online from the new VLAN until after it goes offline from the port.
  - If MAC move is enabled in port security, the user can pass authentication on the new VLAN and come online without having to first go offline from the port. After the user passes authentication on the new VLAN, the original authentication session of the user is deleted from the port.

  To enable the port security MAC move feature, use the **port-security mac-move permit** command.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.
   interface *interface-type interface-number*
3. Enable MAC authentication multi-VLAN mode.
   mac-authentication host-mode multi-vlan
   By default, MAC authentication operates in single-VLAN mode on a port.

Configuring MAC authentication delay

About this task

When both 802.1X authentication and MAC authentication are enabled on a port, you can delay MAC authentication so that 802.1X authentication is preferentially triggered.

If no 802.1X authentication is triggered or 802.1X authentication fails within the delay period, the port continues to process MAC authentication.

Restrictions and guidelines

Do not set the port security mode to **mac-else-userlogin-secure** or **mac-else-userlogin-secure-ext** when you use MAC authentication delay. The delay does not take effect on a port in either of the two modes. For more information about port security modes, see "Configuring port security."

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable MAC authentication delay and set the delay timer.
   mac-authentication timer auth-delay *time*
   By default, MAC authentication delay is disabled.

Including user IP addresses in MAC authentication requests

About this task

IMPORTANT:
This feature can only operate in conjunction with an IMC server.

To avoid IP conflicts that result from changes to static IP addresses, use this feature on a port that has MAC authentication users with static IP addresses.

This feature adds user IP addresses to the MAC authentication requests sent to the authentication server. When MAC authentication is triggered for a user, the device checks the user's IP address for invalidity.

- If the IP address is valid, the device sends a MAC authentication request with the IP address included.
- If the IP address is not a valid host IP address or the triggering packet does not contain an IP address, the device does not initiate MAC authentication.

- If the packet is a DHCP packet with a source IP address of all zeros, the device sends a MAC authentication request without including the IP address. In this case, the IMC server does not examine the user IP address when it performs authentication.

Upon receipt of the authentication request that includes a user's IP address, the IMC server compares the user's IP and MAC addresses with its local IP-MAC mappings.

- If an exact match is found or if no match is found, the user passes MAC authentication. In the latter case, the server creates an IP-MAC mapping for the user.
- If a mapping is found for the MAC address but the IP addresses do not match, the user fails the MAC authentication.

After you specify the **exclude-ip acl** keyword, the applied ACL cannot filter out DHCP packets. If a DHCP packet that carries an invalid IP address triggers MAC authentication, user authentication will fail. To resolve this issue, you can specify the **exclude-dhcpv4** or **exclude-dhcpv6** keyword to prevent users from triggering MAC authentication through DHCP packets.

Restrictions and guidelines

Configure DHCP snooping or ARP snooping, so when users' IP addresses change, the device can quickly update the users' IP addresses and send authentication requests with correct user IP addresses to the authentication server. To configure DHCP snooping, execute the **dhcp snooping enable** and **dhcp snooping binding record** commands. To enable ARP snooping, execute the **arp snooping enable** command. For more information about DHCP snooping and ARP snooping, see ARP configuration and DHCP configuration respectively in *Layer 3—IP Services Configuration Guide*.

Do not use this feature in conjunction with the MAC authentication guest VLAN or guest VSI on a port. The device cannot perform MAC authentication for a user once that user is added to the MAC authentication guest VLAN or guest VSI.

You can specify an ACL to identify source IP addresses that can or cannot trigger MAC authentication. When you configure the ACL, follow these guidelines:

- The specified ACL number represents an IPv4 ACL and an IPv6 ACL with the same number. For example, if the ACL number is 2000, you specify both IPv4 ACL 2000 and IPv6 ACL 2000. The IPv4 ACL and the IPv6 ACL will be used to process IPv4 packets and IPv6 packets, respectively.
- Use permit rules to identify source IP addresses that are valid for MAC authentication. Use deny rules to identify source IP addresses that cannot trigger MAC authentication.
- In the rules, only the action keyword (permit or deny) and the source IP match criteria can take effect. If the ACL is a user-defined ACL (numbered in the range of 5000 to 5999), only the **ipv4**, **ipv6**, and **any** source IP match criteria can take effect.
- As a best practice, configure a deny rule to exclude the IPv6 IP addresses that start with fe80 from triggering MAC authentication.
- If you configure permit rules, add a **deny all** rule at the bottom of the ACL.

IMPORTANT:

If the user host is configured with IPv6, the device might receive packets that contain an IPv6 link-local address, which starts with fe80. MAC authentication failure or incorrect MAC-IP binding will occur if this address is used in MAC authentication. To avoid these issues, configure an ACL to exclude the IPv6 IP addresses that start with fe80.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Include user IP addresses in MAC authentication requests.

   mac-authentication carry user-ip [**exclude-ip acl** *acl-number*] [**exclude-dhcpv4**] [**exclude-dhcpv6**]

   By default, a MAC authentication request does not include the user IP address.

Enabling parallel MAC authentication and 802.1X authentication

About this task

This feature enables a port to perform MAC authentication in parallel with 802.1X authentication when it receives a packet from an unknown MAC address.

This feature applies to the following situation in which MAC authentication can be performed only after 802.1X authentication is completed:

- The port is configured with both 802.1X authentication and MAC authentication and performs MAC-based access control for 802.1X authentication.
- The port is enabled with the 802.1X unicast trigger.

With parallel authentication enabled, the port performs MAC authentication while sending a unicast EAP-Request/Identity packet to trigger 802.1 authentication when it receives a packet from an unknown MAC address.

If MAC authentication succeeds before 802.1X authentication is completed, the port is assigned to the MAC authentication authorization VLAN or VSI. When 802.1X authentication completes, the device manipulates VLAN assignment depending on the authentication result, as follows:

- If 802.1X authentication fails, the MAC authentication result takes effect.
- If 802.1X authentication succeeds, the device manipulates VLAN or VSI assignment based on the 802.1X authentication result.

For the port to perform MAC authentication before it is assigned to the 802.1X guest VLAN or VSI, you must also enable new MAC-triggered 802.1X guest VLAN or VSI assignment delay. For information about new MAC-triggered 802.1X guest VLAN or VSI assignment delay, see "Configuring 802.1X."

Restrictions and guidelines

To configure both 802.1X authentication and MAC authentication on a port, use one of the following methods:

- Enable the 802.1X and MAC authentication features separately on the port.
- Enable port security on the port. The port security mode must be **userlogin-secure-or-mac** or **userlogin-secure-or-mac-ext**.

  For information about port security mode configuration, see "Configuring port security."

For the parallel authentication feature to work correctly, do not enable MAC authentication delay on the port. This feature will delay MAC authentication after 802.1X authentication is triggered.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable parallel MAC authentication and 802.1X authentication on the port.

   mac-authentication parallel-with-dot1x

By default, this feature is disabled.

Configuring RESTful server-assisted MAC authentication user recovery

About this task

RESTful server-assisted MAC authentication user recovery supports the following methods:

- **Automatic recovery**—The device automatically obtains MAC authentication user information and performs a reauthentication after the device or an interface module reboots or after an interface recovers from a failure. This feature recovers the online state of MAC authenticated users quickly without waiting for packets from the MAC authentication users to trigger a reauthentication. It is helpful when the network has a large number of dumb terminals or the operation of dumb terminals is important for services.
- **Manual recovery**—You trigger a recovery manually. Then, the device obtains MAC authentication user information from the RESTful server and performs reauthentication. This method is helpful when automatic recovery fails to recover the online state of all MAC authenticated users because of link flapping.

With this feature, you can configure a maximum of 16 profiles for MAC authentication user recovery. Each profile contains a set of parameters for accessing a RESTful server and the URI from which you obtain MAC authentication user information.

Restrictions and guidelines

To use this feature, you must use an IMC server to act as both authentication and RESTful servers.

This feature is mutually exclusive with the RADIUS accounting-on feature. Do not use the two features together. For more information about the RADIUS accounting-on feature, see "Configuring AAA."

To ensure that the MAC authentication user entries obtained from the RESTful server contain user IP addresses, configure the device to include user IP addresses in the MAC authentication requests sent to the authentication server. For more information about this feature, see "Including user IP addresses in MAC authentication requests."

Procedure

1. Enter system view.

   system-view

2. Configure a MAC authentication user-recovery profile:
   a. Create a profile for MAC authentication user recovery and enter its view.

      mac-authentication user-recovery-profile *profile-name*

   b. Configure the IP address and port number of the RESTful server.

      server-address { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]

      By default, no RESTful servers are configured.

   c. Configure the username and password for accessing the RESTful server.

      login-name *username* [**password** { **cipher** | **simple** } *string*]

      By default, no username or password is configured for accessing the RESTful server.

   d. Configure the NAS IP address used by the device to communicate with the RESTful server.

      nas-ip { *ipv4-address* | **ipv6** *ipv6-address* }

      By default, no NAS IP address is configured for the device to communicate with the RESTful server.

The NAS IP address must be the same as that configured in the authentication RADIUS scheme for the MAC authentication users.

e. Specify the URI for obtaining MAC authentication user information from the RESTful server.

uri *uri-string*

By default, no URIs are specified.

The URI can only be **imcrs/uam/online/notAgingMuteTerminal**. Other URIs cannot take effect.

3. Return to system view.

quit

4. Enable automatic MAC authentication user recovery.

mac-authentication auto-recover-user profile *profile-name*

By default, automatic MAC authentication user recovery is disabled.

5. Return to user view.

quit

6. (Optional.) Manually recover MAC authentication users.

mac-authentication recover-user profile *profile-name* [**interface** *interface-type interface-number*

Tracking the availability of the Web authentication server at a redirect URL

About this task

By default, the device does not track the availability of the Web authentication server at the redirect URL assigned to MAC authentication users. On the device, the state of the Web authentication server will always be active, regardless of its availability. To have the MAC authentication module log off MAC authentication users that have been assigned a redirect URL promptly when the Web authentication server at that URL becomes unavailable, associate that redirect URL with a track entry to detect its connectivity.

As a best practice, configure the track entry associated with the redirect URL to collaborate with an HTTP NQA operation for detection. For more information about Track, see *High Availability Configuration Guide*. For more information about NQA, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

system-view

2. Associate a redirect URL for MAC authentication users with a track entry.

mac-authentication redirect-url *url-string* **track** *track-entry-number*

By default, no redirect URLs for MAC authentication users are associated with a track entry.

Configuring Web proxy ports for URL redirection in MAC authentication

About this task

By default, the device redirects the HTTP or HTTPS requests from a MAC authenticated user to the authorized URL only if the requests are sent from a browser with Web proxy disabled. The device discards these requests if they are sent from a browser configured with a Web proxy.

To prevent the HTTP or HTTPS requests from being discarded, add the TCP port numbers of the Web proxy for HTTP and HTTPS to the device. These TCP port numbers are called Web proxy ports in this document.

Restrictions and guidelines

You can configure a maximum of 64 Web proxy ports for MAC authenticated users.

Specify different Web proxy port numbers for HTTP and HTTPS requests.

Adding or removing a Web proxy port will cause the device to log off all online MAC authenticated users that have been assigned an authorization redirect URL.

Procedure

1. Enter system view.
   system-view
2. Specify a Web proxy port used by MAC authentication users for HTTP or HTTPS.
   mac-authentication web-proxy { **http** | **https** } **port** *port-number*
   By default, no Web proxy ports are specified.

Logging off MAC authentication users

About this task

Perform this task to log off specified MAC authentication users and clear information about these users from the device. These users must perform MAC authentication to come online again.

Procedure

To log off MAC authentication users, execute the following command in user view:

reset mac-authentication access-user [**interface** *interface-type interface-number* | **mac** *mac-address* | **microsegment** *microsegment-id* | **online-type** { **auth-fail-domain** | **critical-domain** | **preauth-domain** | **success** | **url-unavailable-domain** } | **username** *username* | **vlan** *vlan-id* | **vsi** *vsi-name*]

Enabling MAC authentication user logging

About this task

This feature enables the device to generate logs about MAC authentication users and send the logs to the information center. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

To prevent excessive MAC authentication user log entries, use this feature only if you need to analyze abnormal MAC authentication user logins or logouts.

Procedure

1. Enter system view.

   system-view

2. Enable MAC authentication user logging.

   mac-authentication access-user log enable [**failed-login** | **ip-change** | **logoff** | **successful-login**] *

   By default, MAC authentication user logging is disabled.

   If you do not specify any parameters, this command enables all types of MAC authentication user logs.

Display and maintenance commands for MAC authentication

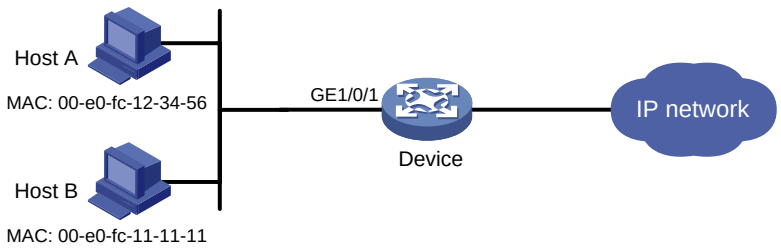
Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display MAC authentication information.	**display mac-authentication** [**interface** *interface-type interface-number*]
Display configuration information for MAC authentication access profiles.	**display mac-authentication access-profile** [**name** *profile-name*]
Display MAC authentication connections.	**display mac-authentication connection** [**open**] [[**m-lag** [**local** | **peer**]] [**interface** *interface-type interface-number* | **online-type** { **auth-fail-domain** | **critical-domain** | **preauth-domain** | **success** | **url-unavailable-domain** } | **slot** *slot-number* | **user-name** *user-name*] | **user-mac** *mac-address*]
Display the MAC addresses of MAC authentication users in a type of MAC authentication microsegment, VLAN, or VSI.	**display mac-authentication mac-address** { **critical-microsegment** | **critical-vlan** | **critical-vsi** | **guest-vlan** | **guest-vsi** } [**interface** *interface-type interface-number*]
Clear MAC authentication statistics.	**reset mac-authentication statistics** [**interface** *interface-type*

Task	Command
	interface-number]
Remove users from the MAC authentication critical VLAN on a port.	**reset mac-authentication critical vlan interface** *interface-type interface-number* [**mac-address** *mac-address*]
Remove users from the MAC authentication critical microsegment on a port.	**reset mac-authentication critical microsegment interface** *interface-type interface-number* [**mac-address** *mac-address*]
Remove users from the MAC authentication guest VLAN on a port.	**reset mac-authentication guest-vlan interface** *interface-type interface-number* [**mac-address** *mac-address*]
Remove users from the MAC authentication critical VSI on a port.	**reset mac-authentication critical vsi interface** *interface-type interface-number* [**mac-address** *mac-address*]
Remove users from the MAC authentication guest VSI on a port.	**reset mac-authentication guest-vsi interface** *interface-type interface-number* [**mac-address** *mac-address*]

MAC authentication configuration examples

Example: Configuring local MAC authentication



Network configuration

As shown in Figure 5, the device performs local MAC authentication on GigabitEthernet 1/0/1 to control Internet access of users.

Configure the device to meet the following requirements:

- Detect whether a user has gone offline every 180 seconds.
- Deny a user for 180 seconds if the user fails MAC authentication.
- Authenticate all users in ISP domain **bbb**.
- Use the MAC address of each user as both the username and password for authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in lower case.

Figure 5 Network diagram

Procedure

Add a network access local user. In this example, configure both the username and password as Host A's MAC address 08-00-27-12-34-56.

```
<Device> system-view
[Device] local-user 08-00-27-12-34-56 class network
[Device-luser-network-08-00-27-12-34-56] password simple 08-00-27-12-34-56
```

Specify the LAN access service for the user.

```
[Device-luser-network-08-00-27-12-34-56] service-type lan-access
[Device-luser-network-08-00-27-12-34-56] quit
```

Configure ISP domain **bbb** to perform local authentication for LAN users.

```
[Device] domain bbb
[Device-isp-bbb] authentication lan-access local
[Device-isp-bbb] quit
```

Enable MAC authentication on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] mac-authentication
[Device-GigabitEthernet1/0/1] quit
```

Specify ISP domain **bbb** as the MAC authentication domain.

```
[Device] mac-authentication domain bbb
```

Configure MAC authentication timers.

```
[Device] mac-authentication timer offline-detect 180
[Device] mac-authentication timer quiet 180
```

Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in lower case.

```
[Device] mac-authentication user-name-format mac-address with-hyphen lowercase
```

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Verifying the configuration

Display MAC authentication settings and statistics to verify your configuration.

```
[Device] display mac-authentication
 Global MAC authentication parameters:
   MAC authentication                          : Enabled
   Authentication method                       : PAP

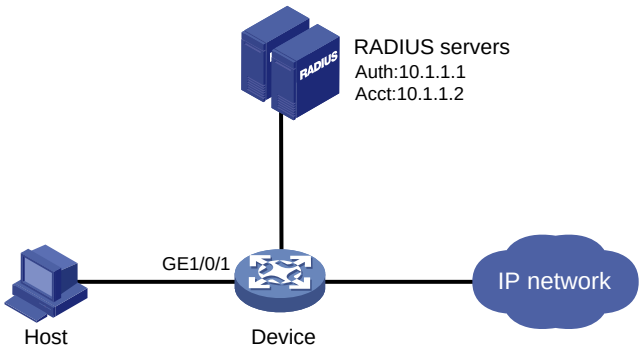
  VLAN tag configuration ignoring          : Disabled
  Max online users                         : 4294967295
  Max online preauth-domain users          : 4294967295
  Max online Auth-Fail-domain users        : 4294967295
  Auth-server-unavailable escape           : Enabled
  Authentication attempts                  : successful 1, failed 0
  Current online users                     : 1
         MAC address       Auth state
         0800-2712-3456    Authenticated
```

The output shows that Host A has passed MAC authentication and has come online. Host B failed MAC authentication and its MAC address is marked as a silent MAC address.

Example: Configuring RADIUS-based MAC authentication



Network configuration

As shown in Figure 6, the device uses RADIUS servers to perform authentication, authorization, and accounting for users. The RADIUS servers use the CHAP authentication method.

To control user access to the Internet by MAC authentication, perform the following tasks:

- Enable MAC authentication globally and on GigabitEthernet 1/0/1.
- Configure the device to use CHAP for MAC authentication.
- Configure the device to detect whether a user has gone offline every 180 seconds.
- Configure the device to deny a user for 180 seconds if the user fails MAC authentication.
- Configure all users to belong to ISP domain **bbb**.
- Use a shared user account for all users, with username **aaa** and password **123456**.

Figure 6 Network diagram

Procedure

Make sure the RADIUS servers and the access device can reach each other.

1. Configure the RADIUS servers to provide authentication, authorization, and accounting services. Create a shared account with username **aaa** and password **123456** for MAC authentication users. (Details not shown.)
2. Configure RADIUS-based MAC authentication on the device:

   # Configure a RADIUS scheme.

   ```
   <Device> system-view
   [Device] radius scheme 2000
   [Device-radius-2000] primary authentication 10.1.1.1 1812
   [Device-radius-2000] primary accounting 10.1.1.2 1813
   [Device-radius-2000] key authentication simple abc
   [Device-radius-2000] key accounting simple abc
   [Device-radius-2000] user-name-format without-domain
   [Device-radius-2000] quit
   ```

   # Specify CHAP as the authentication method for MAC authentication.

   ```
   [Device] mac-authentication authentication-method chap
   ```

   # Apply the RADIUS scheme to ISP domain **bbb** for authentication, authorization, and accounting.

   ```
   [Device] domain bbb
   [Device-isp-bbb] authentication default radius-scheme 2000
   [Device-isp-bbb] authorization default radius-scheme 2000
   ```

```
[Device-isp-bbb] accounting default radius-scheme 2000
[Device-isp-bbb] quit
```

Enable MAC authentication on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] mac-authentication
[Device-GigabitEthernet1/0/1] quit
```

Specify the MAC authentication domain as ISP domain **bbb**.

```
[Device] mac-authentication domain bbb
```

Set MAC authentication timers.

```
[Device] mac-authentication timer offline-detect 180
[Device] mac-authentication timer quiet 180
```

Specify username **aaa** and password **123456** in plain text for the account shared by MAC authentication users.

```
[Device] mac-authentication user-name-format fixed account aaa password simple 123456
```

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Verifying the configuration

Verify the MAC authentication configuration.

```
[Device] display mac-authentication
 Global MAC authentication parameters:
   MAC authentication                         : Enabled

Example: Configuring ACL assignment for MAC authentication

Network configuration

As shown in Figure 7, configure the device to meet the following requirements:

- Use RADIUS servers to perform authentication, authorization, and accounting for users.
- Perform MAC authentication on GigabitEthernet 1/0/1 to control Internet access.
- Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in lower case.
- Use an ACL to deny authenticated users to access the FTP server at 10.0.0.1.

Figure 7 Network diagram

Procedure

Make sure the RADIUS servers and the access device can reach each other.

1. Configure the RADIUS servers:

   # Configure the RADIUS servers to provide authentication, authorization, and accounting services. (Details not shown.)

   # Add a user account with **08-00-27-12-34-56** as both the username and password on each RADIUS server. (Details not shown.)

   # Specify ACL 3000 as the authorization ACL for the user account. (Details not shown.)

2. Configure ACL 3000 to deny packets destined for 10.0.0.1 on the device.

```
<Device> system-view
[Device] acl advanced 3000
[Device-acl-ipv4-adv-3000] rule 0 deny ip destination 10.0.0.1 0
[Device-acl-ipv4-adv-3000] quit
```

3. Configure RADIUS-based MAC authentication on the device:

   # Configure a RADIUS scheme.

```
[Device] radius scheme 2000
[Device-radius-2000] primary authentication 10.1.1.1 1812
[Device-radius-2000] primary accounting 10.1.1.2 1813
[Device-radius-2000] key authentication simple abc
[Device-radius-2000] key accounting simple abc
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

   # Apply the RADIUS scheme to an ISP domain for authentication, authorization, and accounting.

```
[Device] domain bbb
[Device-isp-bbb] authentication default radius-scheme 2000
[Device-isp-bbb] authorization default radius-scheme 2000
[Device-isp-bbb] accounting default radius-scheme 2000
[Device-isp-bbb] quit
```

   # Specify the ISP domain for MAC authentication.

```
[Device] mac-authentication domain bbb
```

   # Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in lower case.

```
[Device] mac-authentication user-name-format mac-address with-hyphen lowercase
```

Enable MAC authentication on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] mac-authentication
[Device-GigabitEthernet1/0/1] quit
```

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Verifying the configuration

Verify the MAC authentication configuration.

```
[Device] display mac-authentication
 Global MAC authentication parameters:
   MAC authentication                          : Enable
   Authentication method                       : PAP
   M-LAG member configuration conflict         : Unknown

   Current online users                       : 1
          MAC address       Auth state
          08-00-2712-3456    Authenticated
```

Verify that you cannot ping the FTP server from the host.

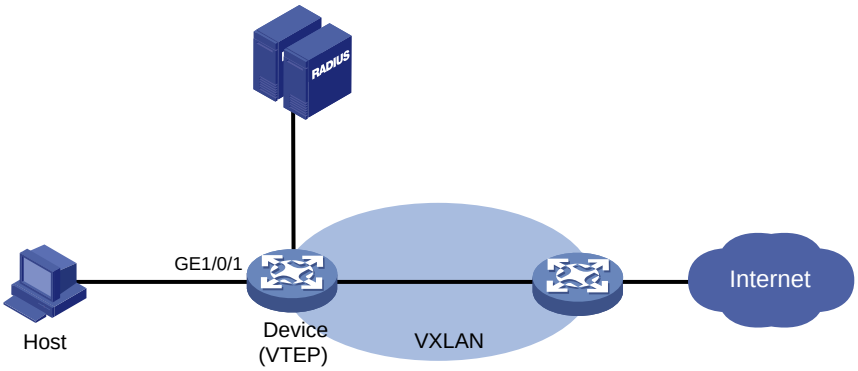
```
C:\>ping 10.0.0.1

Pinging 10.0.0.1 with 32 bytes of data:

Request timed out.
Request timed out.
Request timed out.
Request timed out.

Ping statistics for 10.0.0.1:
   Packets: Sent = 4, Received = 0, Lost = 4 (100% loss),
```

The output shows that ACL 3000 has been assigned to GigabitEthernet 1/0/1 to deny access to the FTP server.



Example: Configuring MAC authentication authorization VSI assignment

Network configuration

As shown in Figure 8, configure the device to meet the following requirements:

- Use RADIUS servers to perform authentication, authorization, and accounting for users.
- Perform MAC authentication on GigabitEthernet 1/0/1 to control Internet access.
- Configure the RADIUS server to assign VSI **bbb** to the host when the host passes MAC authentication.
- Authenticate all users in ISP domain **2000**.
- Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in lower case.

Figure 8 Network diagram

Procedure

Make sure the RADIUS servers and the access device can reach each other.

1. Configure the RADIUS servers:

   # Configure the RADIUS servers to provide authentication, authorization, and accounting services. (Details not shown.)

   # Add a user account with **d4-85-64-be-c6-3e** as both the username and password on each RADIUS server. (Details not shown.)

   # Specify VSI **bbb** as the authorization VSI for the user account. (Details not shown.)

   NOTE:

   If an ADCAM server is used for authentication and authorization, configure VSIs on the server. The server will assign these VSIs to the device. You do not need to configure VSIs on the device.

2. Configure RADIUS-based MAC authentication on the device:

   # Configure a RADIUS scheme.

   ```
   <Device> system-view
   [Device] radius scheme bbb
   [Device-radius-bbb] primary authentication 10.1.1.1
   [Device-radius-bbb] primary accounting 10.1.1.2
   [Device-radius-bbb] key authentication simple bbb
   [Device-radius-bbb] key accounting simple bbb
   [Device-radius-bbb] user-name-format without-domain
   [Device-radius-bbb] quit
   ```

   # Apply the RADIUS scheme to ISP domain **2000** for authentication, authorization, and accounting.

   ```
   [Device] domain 2000
   [Device-isp-2000] authentication lan-access radius-scheme bbb
   [Device-isp-2000] authorization lan-access radius-scheme bbb
   [Device-isp-2000] accounting lan-access radius-scheme bbb
   [Device-isp-2000] quit
   ```

   # Enable MAC authentication on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] mac-authentication
   ```

   # Enable the MAC match mode for dynamic Ethernet service instances on GigabitEthernet 1/0/1.

```
[Device-GigabitEthernet1/0/1] mac-based ac
[Device-GigabitEthernet1/0/1] quit
```

Enable L2VPN.

```
[Device] l2vpn enable
```

Create a VSI named **bbb** and the associated VXLAN.

```
[Device] vsi bbb
[Device-vsi-bbb] vxlan 5
[Device-vsi-bbb-vxlan-5] quit
```

Specify the ISP domain for MAC authentication.

```
[Device] mac-authentication domain 2000
```

Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in lower case.

```
[Device] mac-authentication user-name-format mac-address with-hyphen lowercase
```

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Verifying the configuration

Verify that VSI **bbb** is assigned to the MAC authentication user after the user passes authentication.

```
[Device] display mac-authentication connection
Total connections: 1
Slot ID: 1
User MAC address: d485-64be-c63e

Configuring portal authentication

About portal authentication

Portal authentication controls user access to networks. Portal authenticates a user by the username and password the user enters on a portal authentication page. Typically, portal authentication is deployed on the access layer and vital data entries.

In a portal-enabled network, users can actively initiate portal authentication by visiting the authentication website provided by the portal Web server. Or, they are redirected to the portal authentication page for authentication when they visit other websites.

The device supports Portal 1.0, Portal 2.0, and Portal 3.0.

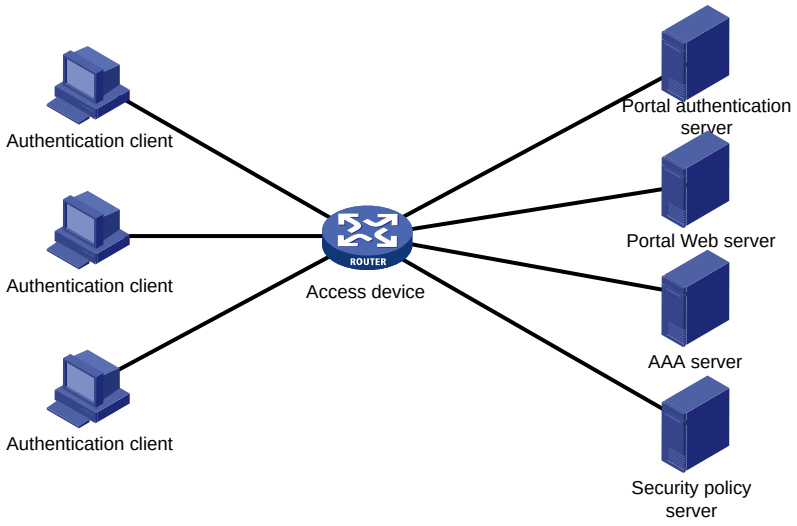
Advantages of portal authentication

Portal authentication has the following advantages:

- Allows users to perform authentication through a Web browser without installing client software.
- Provides ISPs with diversified management choices and extended functions. For example, the ISPs can place advertisements, provide community services, and publish information on the authentication page.
- Supports multiple authentication modes. For example, re-DHCP authentication implements a flexible address assignment scheme and saves public IP addresses. Cross-subnet authentication can authenticate users who reside in a different subnet than the access device.

Extended portal functions

By forcing patching and anti-virus policies, extended portal functions help hosts to defend against viruses. Portal supports the following extended functions:



- **Security check**—Detects after authentication whether or not a user host installs anti-virus software, virus definition file, unauthorized software, and operating system patches.
- **Resource access restriction**—Allows an authenticated user to access certain network resources such as the virus server and the patch server. Users can access more network resources after passing security check.

Security check must cooperate with the IMC security policy server and the iNode client.

Portal system

A typical portal system consists of these basic components: authentication client, access device, portal authentication server, portal Web server, AAA server, and security policy server.

Figure 1 Portal system

Authentication client

An authentication client is a Web browser that runs HTTP/HTTPS or a user host that runs a portal client. Security check for the user host is implemented through the interaction between the portal client and the security policy server. Only the iNode client is supported.

Access device

An access device provides access services. It has the following functions:

- Redirects all HTTP or HTTPS requests of unauthenticated users to the portal Web server.
- Interacts with the portal authentication server and the AAA server to complete authentication, authorization, and accounting.
- Allows users that pass portal authentication to access authorized network resources.

Portal server

A portal server collectively refers to a portal authentication server and portal Web server.

The portal Web server pushes the Web authentication page to authentication clients and forwards user authentication information (username and password) to the portal authentication server. The portal authentication server receives authentication requests from authentication clients and interacts with the access device to authenticate users. The portal Web server is typically integrated with the portal authentication server and it can also be an independent server.

AAA server

The AAA server interacts with the access device to implement authentication, authorization, accounting for portal users. In a portal system, a RADIUS server can perform authentication, authorization, accounting for portal users, and an LDAP server can perform authentication for portal users.

Security policy server

The security policy server interacts with the portal client and the access device for security check and authorization for users. Only hosts that run portal clients can interact with the security policy server.

Portal authentication using a remote portal server

The components of a portal system interact as follows:

1. An unauthenticated user initiates authentication by accessing an Internet website through a Web browser. When receiving the HTTP or HTTPS request, the access device redirects it to the

Web authentication page provided by the portal Web server. The user can also visit the authentication website to log in. The user must log in through the iNode client for extended portal functions.

2. The user enters the authentication information on the authentication page/dialog box and submits the information. The portal Web server forwards the information to the portal authentication server. The portal authentication server processes the information and forwards it to the access device.
3. The access device interacts with the AAA server to implement authentication, authorization, accounting for the user.
4. If security policies are not imposed on the user, the access device allows the authenticated user to access networks.

   If security policies are imposed on the user, the portal client, the access device, and the security policy server interact to check the user host. If the user passes the security check, the security policy server authorizes the user to access resources based on the check result.

Local portal service

System components

As shown in Figure 2, a local portal system consists of an authentication client, access device, and AAA server. The access device acts as both the portal Web server and the portal authentication server to provide the local portal Web service for the authentication client. The authentication client can only be a Web browser, and it cannot be a user host that runs a portal client. Therefore, extended portal functions are not supported and no security policy server is required.

Figure 2 System components

Portal page customization

The portal system pushes different authentication pages to portal users at different stages. The local portal service supports portal page customization. You can customize one or more sets of authentication pages, compress each set of authentication pages to a .zip file, and upload the compressed files to the storage medium of the device.

For more information about authentication page customization, see "Customizing authentication pages."

Portal authentication modes

Portal authentication has three modes: direct authentication, re-DHCP authentication, and cross-subnet authentication. In direct authentication and re-DHCP authentication, no Layer 3 forwarding devices exist between the authentication client and the access device. In cross-subnet authentication, Layer 3 forwarding devices can exist between the authentication client and the access device.

Direct authentication

A user manually configures a public IP address or obtains a public IP address through DHCP. Before authentication, the user can access only the portal Web server and predefined authentication-free websites. After passing authentication, the user can access other network resources. The process of direct authentication is simpler than that of re-DHCP authentication.

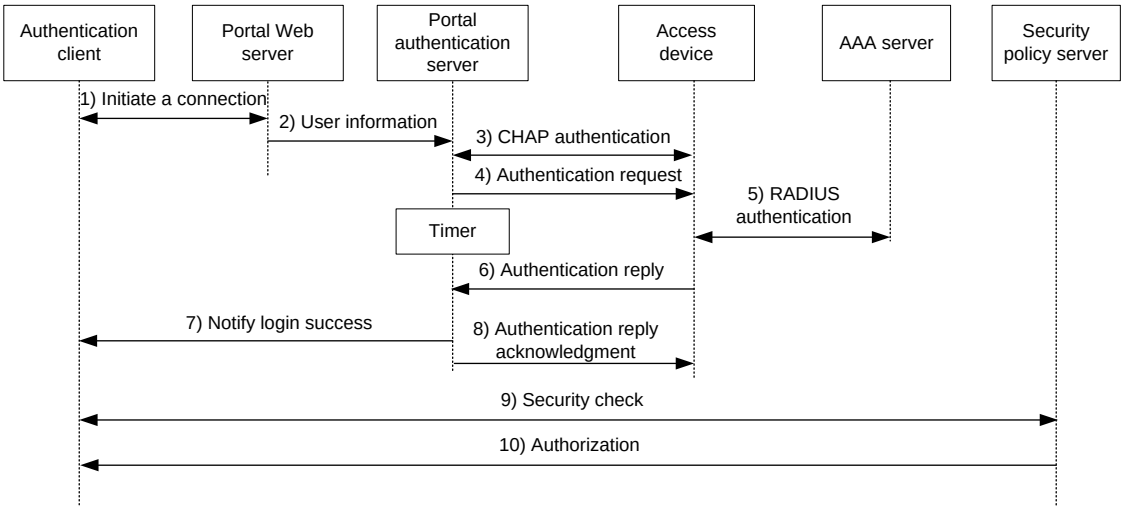
Re-DHCP authentication

Before a user passes authentication, DHCP allocates an IP address (a private IP address) to the user. The user can access only the portal Web server and predefined authentication-free websites. After the user passes authentication, DHCP reallocates an IP address (a public IP address) to the user. The user then can access other network resources. No public IP address is allocated to users who fail authentication. Re-DHCP authentication saves public IP addresses. For example, an ISP can allocate public IP addresses to broadband users only when they access networks beyond the residential community network.

Only the iNode client supports re-DHCP authentication. IPv6 portal authentication does not support the re-DHCP authentication mode.

Cross-subnet authentication

Cross-subnet authentication is similar to direct authentication, except it allows Layer 3 forwarding devices to exist between the authentication client and the access device.



In direct authentication, re-DHCP authentication, and cross-subnet authentication, a user's IP address uniquely identifies the user. After a user passes authentication, the access device generates an ACL for the user based on the user's IP address to control forwarding of the packets from the user. Because no Layer 3 forwarding device exists between authentication clients and the access device in direct authentication and re-DHCP authentication, the access device can learn the user MAC addresses. The access device can enhance its capability of controlling packet forwarding by using the learned MAC addresses.

Portal authentication process

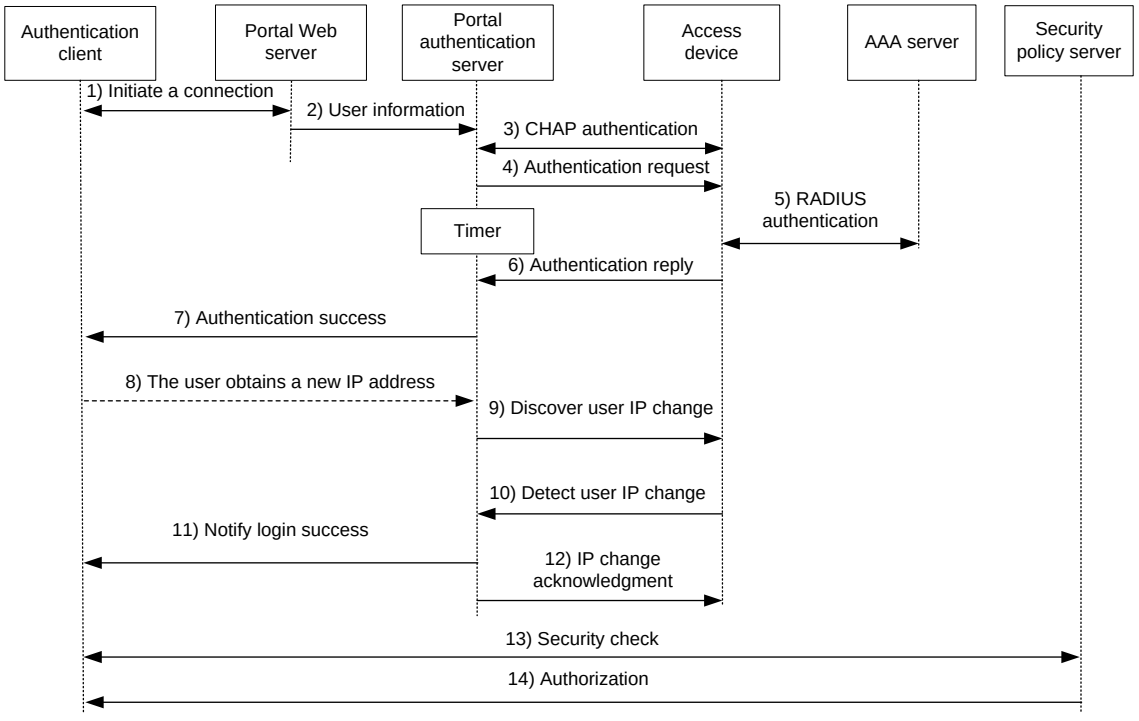
Direct authentication and cross-subnet authentication share the same authentication process. Re-DHCP authentication has a different process as it has two address allocation procedures.

Direct authentication/cross-subnet authentication process (with CHAP/PAP authentication)

Figure 3 Direct authentication/cross-subnet authentication process

The direct/cross-subnet authentication process is as follows:

2. A portal user access the Internet through HTTP or HTTPS, and the HTTP or HTTPS packet arrives at the access device.



- If the packet matches a portal free rule, the access device allows the packet to pass.
- If the packet does not match any portal-free rule, the access device redirects the packet to the portal Web server. The portal Web server pushes the Web authentication page to the user for him to enter his username and password.

3. The portal Web server submits the user authentication information to the portal authentication server.
4. The portal authentication server and the access device exchange CHAP messages. This step is skipped for PAP authentication. The portal authentication server decides the method (CHAP or PAP) to use.
5. The portal authentication server adds the username and password into an authentication request packet and sends it to the access device. Meanwhile, the portal authentication server starts a timer to wait for an authentication reply packet.
6. The access device and the RADIUS server exchange RADIUS packets.
7. The access device sends an authentication reply packet to the portal authentication server to notify authentication success or failure.
8. The portal authentication server sends an authentication success or failure packet to the client.
9. If the authentication is successful, the portal authentication server sends an authentication reply acknowledgment packet to the access device.

   If the client is an iNode client, the authentication process includes step 9 and step 10 for extended portal functions. Otherwise the authentication process is complete.
10. The client and the security policy server exchange security check information. The security policy server detects whether or not the user host installs anti-virus software, virus definition files, unauthorized software, and operating system patches.
11. The security policy server authorizes the user to access certain network resources based on the check result. The access device saves the authorization information and uses it to control access of the user.

Re-DHCP authentication process (with CHAP/PAP authentication)

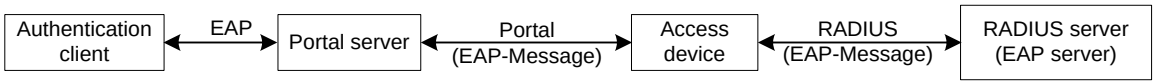
Figure 4 Re-DHCP authentication process

The re-DHCP authentication process is as follows:

Step 1 through step 7 are the same as those in the direct authentication/cross-subnet authentication process.

2. A portal user access the Internet through HTTP or HTTPS, and the HTTP or HTTPS packet arrives at the access device.
    - If the packet matches a portal free rule, the access device allows the packet to pass.
    - If the packet does not match any portal-free rule, the access device redirects the packet to the portal Web server. The portal Web server pushes the Web authentication page to the user for him to enter his username and password.
3. The portal Web server submits the user authentication information to the portal authentication server.
4. The portal authentication server and the access device exchange CHAP messages. This step is skipped for PAP authentication. The portal authentication server decides the method (CHAP or PAP) to use.
5. The portal authentication server adds the username and password into an authentication request packet and sends it to the access device. Meanwhile, the portal authentication server starts a timer to wait for an authentication reply packet.
6. The access device and the RADIUS server exchange RADIUS packets.
7. The access device sends an authentication reply packet to the portal authentication server to notify authentication success or failure.
8. The portal authentication server sends an authentication success or failure packet to the client.
9. After receiving the authentication success packet, the client obtains a public IP address through DHCP. The client then notifies the portal authentication server that it has a public IP address.
10. The portal authentication server notifies the access device that the client has obtained a public IP address.
11. The access device detects the IP change of the client through DHCP and then notifies the portal authentication server that it has detected an IP change of the client IP.
12. After receiving the IP change notification packets sent by the client and the access device, the portal authentication server notifies the client of login success.
13. The portal authentication server sends an IP change acknowledgment packet to the access device.
14. The client and the security policy server exchanges security check information. The security policy server detects whether or not the user host installs anti-virus software, virus definition files, unauthorized software, and operating system patches.
15. The security policy server authorizes the user to access certain network resources based on the check result. The access device saves the authorization information and uses it to control access of the user.

Step 13 and step 14 are for extended portal functions.



Portal support for EAP

To use portal authentication that supports EAP, the portal authentication server and client must be the IMC portal server and the iNode portal client. Local portal authentication does not support EAP authentication.

Compared with username and password based authentication, digital certificate-based authentication ensures higher security.

The Extensible Authentication Protocol (EAP) supports several digital certificate-based authentication methods, for example, EAP-TLS. Working together with EAP, portal authentication can implement digital certificate-based user authentication.

Figure 5 Portal support for EAP working flow diagram

As shown in Figure 5, the authentication client and the portal authentication server exchange EAP authentication packets. The portal authentication server and the access device exchange portal authentication packets that carry the EAP-Message attributes. The access device and the RADIUS server exchange RADIUS packets that carry the EAP-Message attributes. The RADIUS server that supports the EAP server function processes the EAP packets encapsulated in the EAP-Message attributes, and provides the EAP authentication result.

The access device does not process but only transports EAP-Message attributes between the portal authentication server and the RADIUS server. Therefore, the access device requires no additional configuration to support EAP authentication.

Portal filtering rules

The access device uses portal filtering rules to control user traffic forwarding.

Basic rules

Based on the configuration and authentication status of portal users, the device generates the following categories of portal filtering rules:

- **Category 1**—The rule permits user packets that are destined for the portal Web server and packets that match the portal-free rules to pass through.
- **Category 2**—For an authenticated user with neither ACL nor microsegment authorized, the rule allows the user to access any destination network resources. For an authenticated user with an ACL or microsegment authorized, the rule allows users to access resources permitted by the ACL or microsegment. The device adds the rule when a user comes online and deletes the rule when the user goes offline.

  The device supports the following types of authorization ACLs:

  - Basic ACLs (ACL 2000 to ACL 2999).
  - Advanced ACLs (ACL 3000 to ACL 3999).
  - Layer 2 ACLs (ACL 4000 to ACL 4999).
  - User-defined ACLs (ACL 5000 to ACL 5999).

  For an authorization ACL to take effect, make sure the ACL exists and has ACL rules excluding rules configured with the **`counting`**, **`established`**, **`fragment`**, **`source-mac`**, **`source-ip`**, or **`logging`** keyword. For more information about ACL rules, see ACL commands in *ACL and QoS Command Reference*.

  If the authorization microsegment ID does not exist or microsegmentation is disabled, the authorization microsegment does not take effect. The microsegment authorization feature is supported in only direct portal authentication mode. The restrictions for configurations of authorization ACLs and microsegments are as follows:

  - An authorization ACL and authorization microsegment can both take effect, but source criteria cannot be configured if the ACL is a basic ACL and microsegment cannot be configured if the ACL is an advanced ACL.
  - When ACL resource sharing in shared portal authentication mode is enabled, the microsegment authorization feature does not take effect.

  For more information about microsegmentation, see "Configuring microsegmentation."
- **Category 3**—The rule redirects all HTTP or HTTPS requests from unauthenticated users to the portal Web server.

- **Category 4**—For direct authentication and cross-subnet authentication, the rule forbids any user packets to pass through. For re-DHCP authentication, the device forbids user packets with private source addresses to pass.

After receiving a user packet, the device compares the packet against the filtering rules from category 1 to category 4. Once the packet matches a rule, the matching process completes.

MAC-based quick portal authentication

MAC-based quick portal authentication is applicable to scenarios where users access the network frequently. It allows users to pass authentication without entering a username and password. MAC-based quick portal authentication is also called MAC-trigger authentication or MAC-based transparent authentication.

A MAC binding server is required for MAC-trigger authentication. The MAC binding server records the MAC-to-account bindings of portal users for authentication. The account contains the portal authentication information of the user, including username and password.

Only direct authentication supports MAC-based quick portal authentication.

The authentication is implemented as follows:

1. When a user accesses the network for the first time, the access device generates a MAC-trigger entry that records the user's MAC address and access interface. The user can access the network without performing portal authentication if the user's network traffic is below the free-traffic threshold.
2. When the user's network traffic reaches the threshold, the access device sends a MAC binding query to the MAC binding server.
3. The MAC binding server checks whether the MAC address of the user is bound with a portal user account.
   - If a matching MAC-account binding exists, the MAC binding server sends the user authentication information to the access device to initiate portal authentication. The user is authenticated without entering the username and password.
     - If the user fails portal authentication, an authentication failure message is returned to the user. The MAC-trigger entry of the user on the access device is deleted when the entry ages out.
     - If the user passes portal authentication, the access device deletes the MAC-trigger entry of the user.
   - If no matching MAC-account binding exists, the MAC binding server notifies the access device to perform normal portal authentication for the user.
     - If the user fails portal authentication, an authentication failure message is returned to the user. The whole process is finished.
     - If the user passes portal authentication, the access device sends the user's MAC address and authentication information to the MAC binding server for MAC-account binding. Additionally, the access device deletes the MAC-trigger entry of the user.

NOTE:

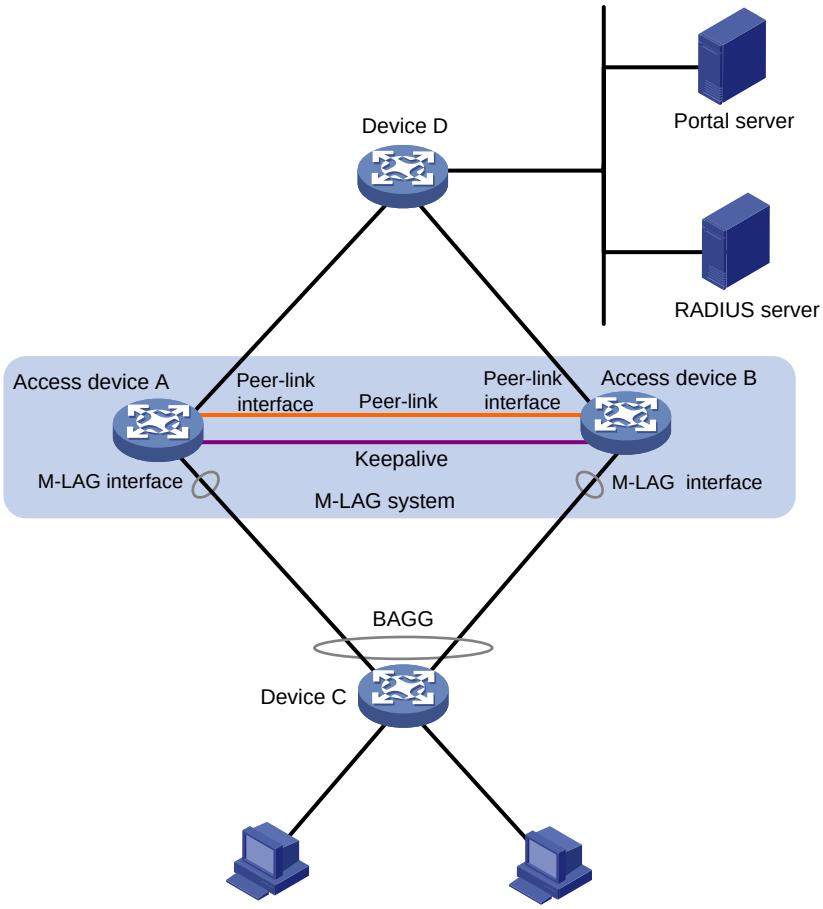
For information about MAC binding server configuration, see the user manual of the server.

IP-based quick portal authentication

IP-based quick portal authentication is applicable to scenarios where users access the network frequently. It allows users to pass authentication without entering a username and password. IP-based quick portal authentication is also called IP-trigger authentication or IP-based transparent authentication.

After IP-based quick portal authentication is enabled, the device adds an IP-trigger entry for a user on receiving user traffic that matches the IP-trigger ACL. The IP-trigger entry records the user's IP address, access interface, VLAN ID, and the entry aging time. The device sends the user's authentication credentials (using the user IP address as both the username and password) to the RADIUS server for authentication. In this way, the device provides portal authentication transparently to the user.

Only direct authentication and cross-subnet authentication support IP-based quick portal authentication.



Portal support for M-LAG

Portal authentication supports M-LAG to improve high availability of the access device.

As shown in Figure 6, Device A and Device B form an M-LAG system. The M-LAG system acts as an access device to provide redundancy and load sharing. For more information about M-LAG, see *Layer 2—LAN Switching Configuration Guide*.

In an M-LAG system, after portal users pass authentication on an M-LAG member device, the M-LAG member device will synchronize data of the users to the peer member device for backup. When the M-LAG member device fails, the peer member device can use the backup user data to process services for the portal users. This ensures user service continuity.

Figure 6 Support of portal for M-LAG

Portal support for microsegment authorization

Authorization microsegment

The microsegmentation feature can perform access control on network access users based on the microsegment groups to which the users belong. When a portal user comes online after passing direct portal authentication (not the shared mode) and an authorization microsegment is assigned by the RADIUS server to the user, the device filters the user traffic on the access interface according to the authorization microsegment. For more information about microsegmentation, see "Configuring microsegmentation."

Portal critical microsegment

The portal critical microsegment feature allows users to access critical microsegments (specific microsegment resources) when all authentication servers are unreachable. This feature takes effect only in RADIUS authentication. If other authentication methods are adopted, users will not be accommodated to the critical microsegments.

In direct portal authentication mode, after a critical profile is specified on the access interface of a user, the user is accommodated to the critical microsegment when no authentication server is reachable during authentication. The user can access the network resources in the authorized critical microsegment. When the user performs authentication again and no authentication server is reachable, the user will stay in the critical microsegment. When the authentication server is reachable and the user performs authentication again, the user leaves the critical microsegment no matter whether authentication succeeded or failed.

Restrictions and guidelines: Portal configuration

In portal authentication, the device can redirect users' HTTPS requests to the portal Web server. You can use one of the following local certificates for the HTTPS redirect service according to the security requirements and the configuration complexity:

- **Self-signed certificate**—Using this type of certificate is simple in configuration but has low security. You do not need to associate an SSL server policy with the HTTPS redirect service and the default SSL parameters are used. However, a self-signed certificate is not trusted by the browser. When the device redirects HTTPS requests to the portal Web server, a certificate security warning prompt might appear on the browser. If you accept the security risks stated in the prompt, you can ignore the prompt to browse the page.
- **CA-signed certificate**—Using this type of certificate is complex in configuration but has high security. You must obtain a CA certificate, request a local certificate from the CA, create an SSL server policy (with policy name of **https_redirect**), and associate the SSL server policy with the HTTPS redirect service.

For more information about digital certificates, see "Configuring PKI". For more information about the SSL server policy configuration, see "Configuring SSL".

Portal authentication through Web does not support security check for users. To implement security check, the client must be the iNode client.

Portal authentication supports NAT traversal whether it is initiated by a Web client or an iNode client. NAT traversal must be configured when the portal client is on a private network and the portal server is on a public network.

If the portal clients and the portal server belong to different VPNs, the Rule ARP entry feature will cause the portal clients to go offline abnormally. To avoid this issue, execute the **`undo portal refresh arp enable`** command to disable the Rule ARP entry feature for portal clients.

Portal authentication tasks at a glance

To configure portal authentication, perform the following tasks:

1. Configuring a remote portal service

   Perform this task if the access device does not act as a portal authentication server or portal Web server.

   - Configuring a remote portal authentication server
   - Configuring a portal Web server

2. Configuring a local portal service

   Perform this task if the access device acts as a portal authentication server and portal Web server.

   - Configuring local portal service features
   - Configuring a portal Web server

3. Enabling portal authentication and specifying a portal Web server
   - Enabling portal authentication on an interface
   - Specifying a portal Web server on an interface
   - Enabling portal to support IPv4/IPv6 dual stack

     Perform this task if dual-stack portal users exist on the network.

4. (Optional.) Configure parameters for preauthentication portal users
   - Configuring a portal preauthentication domain
   - Specifying a preauthentication IP address pool
5. (Optional.) Specifying a portal authentication domain
6. (Optional.) Controlling portal user access
   - Configuring a portal-free rule
   - Configuring an authentication source subnet
   - Configuring an authentication destination subnet
   - Configuring support of Web proxy for portal authentication
   - Checking the issuing of category-2 portal filtering rules
   - Setting the maximum number of portal users
   - Enabling strict-checking on portal authorization information
   - Allowing only users with DHCP-assigned IP addresses to pass portal authentication
   - Enabling portal roaming
   - Configuring the portal fail-permit feature
7. (Optional.) Configuring portal detection features
   - Configuring online detection of portal users
   - Configuring portal authentication server detection
   - Configuring portal Web server detection
   - Configuring portal user synchronization
8. (Optional.) Configuring attributes for portal packets and RADIUS packets
   - Configuring portal packet attributes

     You can configure the BAS-IP or BAS-IPv6 attribute for portal packets and specify the device ID.

   - Configuring attributes for RADIUS packets

You can configure the NAS-Port-Id and NAS-Port-Type attributes and apply a NAS-ID profile to an interface.

9. (Optional.) Configuring MAC-based quick portal authentication
   a. Configuring a MAC binding server
   b. Specifying a MAC binding server on an interface
   c. Configuring cloud MAC-trigger authentication
10. (Optional.) Configuring IP-based quick portal authentication
11. (Optional.) Configuring portal authentication to support M-LAG
12. (Optional.) Configuring online and offline related features for portal users
    - Logging out online portal users
    - Enabling portal user login/logout logging
13. (Optional.) Configuring extended portal authentication features
    - Disabling the Rule ARP or ND entry feature for portal clients
    - Configuring Web redirect
14. Obtaining user access information from ARP or ND entries

    This task is required in a remote Web authentication network.

Prerequisites for portal authentication

The portal feature provides a solution for user identity authentication and security check. To complete user identity authentication, portal must cooperate with RADIUS.

Before you configure portal, you must complete the following tasks:

- The portal authentication server, portal Web server, and RADIUS server have been installed and configured correctly.
- To use the re-DHCP portal authentication mode, make sure the DHCP relay agent is enabled on the access device, and the DHCP server is installed and configured correctly.
- The portal client, access device, and servers can reach each other.
- To use the remote RADIUS server, configure usernames and passwords on the RADIUS server, and configure the RADIUS client on the access device. For information about RADIUS client configuration, see "Configuring AAA."
- To implement extended portal functions, install and configure IMC EAD. Make sure the ACLs configured on the access device correspond to the isolation ACL and the security ACL on the security policy server. For installation and configuration about the security policy server, see *IMC EAD Security Policy Help*.

Configuring a remote portal authentication server

About this task

With portal authentication enabled, the device searches for a portal authentication server for a received portal request packet according to the source IP address and VPN information of the packet.

- If a matching portal authentication server is found, the device regards the packet valid and sends an authentication response packet to the portal authentication server. After a user logs in to the device, the user interacts with the portal authentication server as needed.
- If no matching portal authentication server is found, the device drops the packet.

Restrictions and guidelines

Do not delete a portal authentication server in use. Otherwise, users authenticated by that server cannot log out correctly.

Procedure

1. Enter system view.

   system-view

2. Create a portal authentication server and enter its view.

   portal server *server-name*

   You can create multiple portal authentication servers.

3. Specify the IP address of the portal authentication server.

   IPv4:

   ip *ipv4-address* [**vpn-instance** *vpn-instance-name*] [**key** { **cipher** | **simple** } *string*]

   IPv6:

   ipv6 *ipv6-address* [**vpn-instance** *vpn-instance-name*] [**key** { **cipher** | **simple** } *string*]

4. (Optional.) Set the destination UDP port number used by the device to send unsolicited portal packets to the portal authentication server.

   port *port-number*

   By default, the UDP port number is 50100.

   This port number must be the same as the listening port number specified on the portal authentication server.

5. (Optional.) Specify the portal authentication server type.

   server-type { **cmcc** | **imc** }

   By default, the portal authentication server type is IMC.

   The specified server type must be the same as the type of the portal authentication server actually used.

6. (Optional.) Configure the device to periodically register with the portal authentication server.

   server-register [**interval** *interval-value*]

   By default, the device does not register with a portal authentication server.

Configuring a portal Web server

Portal Web server tasks at a glance

To configure a portal Web server, perform the following tasks:

1. Configure basic parameters for a portal Web server
2. (Optional.) Enabling the captive-bypass feature
3. (Optional.) Configuring a match rule for URL redirection
4. (Optional.) Configuring unescaped special characters for portal Web server URLs redirected to users

Configure basic parameters for a portal Web server

1. Enter system view.

system-view

2. Create a portal Web server and enter its view.

   portal web-server *server-name*

   You can create multiple portal Web servers.

3. Specify the VPN instance to which the portal Web server belongs.

   vpn-instance *vpn-instance-name*

   By default, the portal Web server belongs to the public network.

4. Specify the URL of the portal Web server.

   url *url-string*

   By default, no URL is specified for a portal Web server.

5. Configure the parameters to be carried in the URL when the device redirects it to users.

   url-parameter *param-name* { **original-url** | **source-address** | **source-mac** [**format section** { **1** | **3** | **6** } { **lowercase** | **uppercase** }] [**encryption** { **aes** | **des** } **key** { **cipher** | **simple** } *string*] | **value** *expression* }

   By default, no redirection URL parameters are configured.

6. (Optional.) Specify the portal Web server type.

   server-type { **cmcc** | **imc** | **ise** | **oauth** }

   By default, the portal Web server type is IMC.

   This configuration is applicable to only to the remote portal service.

   The specified server type must be the same as the type of the portal Web server actually used.

Enabling the captive-bypass feature

About this task

Typically, when iOS mobile devices or some Android mobile devices are connected a portal-enabled network, the device pushes the authentication page to the mobile devices.

The captive-bypass feature enables the device to push the portal authentication page to the iOS and Android devices only when the users access the Internet by using a browser. If the users do not perform authentication but press the home button to return to the desktop, the Wi-Fi connection is terminated. To maintain the Wi-Fi connection in such cases, you can enable the optimized captive-bypass feature.

When optimized captive-bypass is enabled, the portal authentication page is automatically pushed to iOS mobile devices after they connects to the network. Users can perform authentication on the page or press the home button to return to the desktop without performing authentication, and the Wi-Fi connection is not terminated.

When an iOS client is connected to a network, it automatically sends a server reachability detection packet to determine whether the Apple server is reachable. If the server is reachable, the Wi-Fi connection displays connected. If the server is not reachable, the Wi-Fi connection is terminated.

When the network condition is poor, the device cannot detect a server reachability detection packet from an iOS mobile client within the captive-bypass detection timeout time. The client cannot receive a response for the server reachability detection packet, and therefore it determines the server to be unreachable and terminates the Wi-Fi connection. To avoid Wi-Fi disconnections caused by server reachability detection failure, set a longer captive-bypass detection timeout time when the network condition is poor.

Procedure

1. Enter system view.

   system-view

2. Enter portal Web server view.

   portal web-server *server-name*

3. Enable the captive-pass feature.

   captive-bypass [**android** | **ios** [**optimize**]] **enable**

   By default, the captive-bypass feature is disabled. The device automatically pushes the portal authentication page to iOS mobile devices and some Android mobile devices when they are connected to a portal-enabled network.

4. (Optional.) Set the captive-bypass detection timeout time.

   a. Return to system view.

      quit

   b. Set the captive-bypass detection timeout time.

      portal captive-bypass optimize delay *seconds*

      By default, the captive-bypass detection timeout is 6 seconds.

Configuring a match rule for URL redirection

About this task

A URL redirection match rule matches HTTP or HTTPS requests by user-requested URL or User-Agent information, and redirects the matching requests to the specified redirection URL. Therefore, URL redirection match rules allow for more flexible URL redirection than the **url** command. The **url** command is only used to redirect HTTP or HTTPS requests from unauthenticated users to the portal Web server for authentication.

Restrictions and guidelines

For a user to successfully access a redirection URL, configure a portal-free rule to allow HTTP or HTTPS requests destined for the redirection URL to pass. For information about configuring portal-free rules, see the **portal free-rule** command.

If both the **url** and **if-match** commands are executed, the **if-match** command takes priority to perform URL redirection.

Procedure

1. Enter system view.

   system-view

2. Enter portal Web server view.

   portal web-server *server-name*

3. Configure a match rule for URL redirection.

   if-match { **original-url** *url-string* **redirect-url** *url-string* [**url-param-encryption** { **aes** | **des** } **key** { **cipher** | **simple** } *string*] | **user-agent** *string* **redirect-url** *url-string* }

Configuring unescaped special characters for portal Web server URLs redirected to users

About this task

By default, the device escapes all special characters in the portal Web server URL redirected to users. This practice converts special characters to a secure form to prevent the clients from misinterpreting them as syntax symbols or instructions.

However, a portal Web server might be unable to recognize the escape characters for certain special characters in URLs. In this case, you must configure the device to not escape these special characters so the portal Web server can correctly deliver the Web authentication page to users.

Prerequisites

Before you specify unescaped special characters, identify the escape characters that the portal Web server cannot recognize.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Specify unescaped special characters for portal Web server URLs redirected to users.

   ```
   portal url-unescape-chars character-string
   ```

   By default, the device escapes all special characters in portal Web server URLs redirected to users.

Configuring local portal service features

About the local portal service

After a local portal service is configured, the device acts as the portal Web server and portal authentication server to perform portal authentication on users. The portal authentication page file is saved in the root directory of the device.

Restrictions and guidelines for configuring local portal service features

For an interface to use the local portal service, the URL of the portal Web server specified for the interface must meet the following requirements:

- The IP address in the URL must be the IP address of a Layer 3 interface (except 127.0.0.1) on the device, and the IP address must be reachable to portal clients.
- The URL must be ended with **/portal/**. For example: **https://1.1.1.1/portal/**.

The device provides a default authentication page file. To use customized authentication pages, you must edit the authentication pages, compress them to a file, and then upload the file to the device. On the device, specify the file as the default authentication page file.

Customizing authentication pages

About this task

Authentication pages are HTML files. Local portal authentication requires the following authentication pages:

- Logon page
- Logon success page
- Logon failure page
- Online page
- System busy page
- Logoff success page

You must customize the authentication pages, including the page elements that the authentication pages will use, for example, **back.jpg** for authentication page **Logon.htm**.

Follow the authentication page customization rules when you edit the authentication page files.

File name rules

The names of the main authentication page files are fixed (see Table 1). You can define the names of the files other than the main authentication page files. File names and directory names are case insensitive.

Table 1 Main authentication page file names

Main authentication page	File name
Logon page	logon.htm
Logon success page	logonSuccess.htm
Logon failure page	logonFail.htm
Online page Pushed after the user gets online for online notification	online.htm
System busy page Pushed when the system is busy or the user is in the logon process	busy.htm
Logoff success page	logoffSuccess.htm

Page request rules

The local portal Web server supports only Get and Post requests.

- **Get requests**—Used to get the static files in the authentication pages and allow no recursion. For example, if file **Logon.htm** includes contents that perform Get action on file **ca.htm**, file **ca.htm** cannot include any reference to file **Logon.htm**.
- **Post requests**—Used when users submit username and password pairs, log in, and log out.

Post request attribute rules

1. Observe the following requirements when editing a form of an authentication page:
   - An authentication page can have multiple forms, but there must be one and only one form whose action is **logon.cgi**. Otherwise, user information cannot be sent to the access device.
   - The username attribute is fixed as **PtUser**. The password attribute is fixed as **PtPwd**.
   - The value of the **PtButton** attribute is either **Logon** or **Logoff**, which indicates the action that the user requests.
   - A logon Post request must contain **PtUser**, **PtPwd**, and **PtButton** attributes.
   - A logoff Post request must contain the **PtButton** attribute.
2. Authentication pages **logon.htm** and **logonFail.htm** must contain the logon Post request.

   The following example shows part of the script in page **logon.htm**.

```
<form action=logon.cgi method = post >
<p>User name:<input type="text" name = "PtUser" style="width:160px;height:22px"
maxlength=64>
<p>Password :<input type="password" name = "PtPwd" style="width:160px;height:22px"
maxlength=32>
<p><input type=SUBMIT value="Logon" name = "PtButton" style="width:60px;"
onclick="form.action=form.action+location.search;">
</form>
```

3. Authentication pages **logonSuccess.htm** and **online.htm** must contain the logoff Post request.

   The following example shows part of the script in page **online.htm**.

```
<form action=logon.cgi method = post >
<p><input type=SUBMIT value="Logoff" name="PtButton" style="width:60px;">
</form>
```

Page file compression and saving rules

You must compress the authentication pages and their page elements into a standard zip file.

- The name of a zip file can contain only letters, numbers, and underscores.
- The authentication pages must be placed in the root directory of the zip file.
- Zip files can be transferred to the device through FTP or TFTP and must be saved in the root directory of the device.

  Examples of zip files on the device:

```
<Sysname> dir
Directory of flash:
   1     -rw-      1405  Feb 28 2008 15:53:20   ssid1.zip
   0     -rw-      1405  Feb 28 2008 15:53:31   ssid2.zip
   2     -rw-      1405  Feb 28 2008 15:53:39   ssid3.zip
   3     -rw-      1405  Feb 28 2008 15:53:44   ssid4.zip
2540 KB total (1319 KB free)
```

Redirecting authenticated users to a specific webpage

To make the device automatically redirect authenticated users to a specific webpage, do the following in logon.htm and logonSuccess.htm:

1. In logon.htm, set the target attribute of Form to _**blank**.

   See the contents in gray:

```
<form method=post action=logon.cgi target="_blank">
```

2. Add the function for page loading pt_init() to LogonSuccess.htm.

   See the contents in gray:

```
<html>
<head>
<title>LogonSuccess</title>
<script type="text/javascript" language="javascript"
src="pt_private.js"></script>
</head>
<body onload="pt_init();" onbeforeunload="return pt_unload();">
... ...
</body>
</html>
```

Configuring a local portal Web service

Prerequisites

Before you configure an HTTPS-based local portal Web service, you must complete the following tasks:

- Configure a PKI policy, obtain the CA certificate, and request a local certificate. For more information, see "Configuring PKI."
- Configure an SSL server policy, and specify the PKI domain configured in the PKI policy.

During SSL connection establishment, the user browser might display a message that it cannot verify server identity by certificate. For users to perform portal authentication without checking such a message, configure an SSL server policy to request a client-trusted certificate on the device. The name of the policy must be **https_redirect**. For more information about SSL server policy configuration, see "Configuring SSL."

Procedure

1. Enter system view.

   system-view

2. Enable HTTP- or HTTPS-based local portal Web service and enter its view.

   portal local-web-server { **http** | **https ssl-server-policy** *policy-name* [**tcp-port** *port-number*] }

3. Specify the default authentication page file for the local portal Web service.

   default-logon-page *filename*

   By default, the default authentication page file for a local portal Web service is file **defaultfile.zip**.

4. (Optional.) Configure the HTTP or HTTPS listening TCP port for the local portal Web service.

   tcp-port *port-number*

   By default, the HTTP service listening port number is 80 and the HTTPS service listening port number is the TCP port number set by the **portal local-web-server** command.

5. (Optional.) Bind the endpoint name to an authentication page file.

   logon-page bind device-name *device-name* **file** *file-name*

   By default, no endpoint name is bound to an authentication page file.

Enabling portal authentication on an interface

Restrictions and guidelines

When you enable portal authentication on an interface, follow these restrictions and guidelines:

- Cross-subnet authentication mode (**layer3**) does not require Layer 3 forwarding devices between the access device and the portal authentication clients. However, if a Layer 3 forwarding device exists between the authentication client and the access device, you must use the cross-subnet portal authentication mode.
- You can enable both IPv4 portal authentication and IPv6 portal authentication on an interface.

When you configure re-DHCP portal authentication on an interface, follow these restrictions and guidelines:

- Make sure the interface has a valid IP address before you enable re-DHCP portal authentication on the interface.
- With re-DHCP portal authentication, configure authorized ARP on the interface as a best practice to make sure only valid users can access the network. With authorized ARP configured on the interface, the interface learns ARP entries only from the users who have obtained a public address from DHCP.
- For successful re-DHCP portal authentication, make sure the BAS-IP or BAS-IPv6 attribute value is the same as the device IP address specified on the portal authentication server. To configure the attribute, use the **portal** { **bas-ip** | **bas-ipv6** } command.
- An IPv6 portal server does not support re-DHCP portal authentication.

Portal authentication supports both HTTP redirect and HTTPS redirect. The default HTTPS redirect listening port number on the device is 6654. To change the HTTPS redirect listening port number, see HTTP redirect configuration in *Layer 3—IP Services Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Enable portal authentication.
   IPv4:
   portal enable method { **direct** [**shared**] | **layer3** | **redhcp** [**shared**] }
   IPv6:
   portal ipv6 enable method { **direct** [**shared**] | **layer3** }
   By default, portal authentication on an interface is disabled.

Specifying a portal Web server on an interface

About this task

With a portal Web server specified on an interface, the device redirects the HTTP requests of portal users on the interface to the portal Web server.

You can specify both an IPv4 portal Web server and an IPv6 portal Web server on an interface.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Specify a portal Web server on the interface.
   portal [**ipv6**] **apply web-server** *server-name* [**fail-permit** | **secondary**]
   By default, no portal Web servers are specified on an interface.

Enabling portal to support IPv4/IPv6 dual stack

About this task

When portal is enabled to support IPv4/IPv6 dual stack, dual-stack portal users can access both IPv4 and IPv6 networks after passing one type (IPv4 or IPv6) of portal authentication.

The following describes the mechanism of how portal supports IPv4/IPv6 dual stack:

1. A portal user passes portal authentication of one IP stack (the first stack, IPv4 or IPv6). The user can access network resources of this IP stack.
2. The device records the user's MAC address and IP address in the portal user entry for the user.
3. Upon receiving a packet of the other IP stack (the second stack, IPv6 or IPv4) from the user, the device compares the source MAC address with that in the portal user entry for the user.
   - If the MAC addresses are the same, the device allows the user to access network resources of the second stack without reauthentication.
   - If the MAC addresses are different, the user needs to perform portal authentication of the second stack.

Restrictions and guidelines

This configuration takes effect on an interface only when both direct IPv4 portal authentication and direct IPv6 portal authentication are enabled on the interface.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Enable portal to support IPv4/IPv6 dual stack.
   portal dual-stack enable

   By default, portal support for IPv4/IPv6 dual stack is disabled. Dual-stack portal users can access only one type (IPv4 or IPv6) of network after passing that type of portal authentication.

Configuring a portal preauthentication domain

About this task

A portal preauthentication domain defines user attributes assigned to preauthentication portal users on a portal-enabled interface after the users obtain IP addresses. Before the preauthentication users pass portal authentication, they have limited access to the network based on the assigned user attributes (such as ACL). After the users pass portal authentication, they are assigned new attributes by the AAA server. After the users go offline, they are re-assigned user attributes in the preauthentication domain.

Restrictions and guidelines

The portal preauthentication domain takes effect only on portal users with IP addresses obtained through DHCP or DHCPv6.

The portal preauthentication domain does not take effect on interfaces enabled with cross-subnet portal authentication.

Make sure you specify an existing ISP domain as a portal preauthentication domain. If the specified ISP domain does not exist, the device might operate incorrectly.

You must delete a preauthentication domain (by using the **undo portal** [**ipv6**] **pre-auth domain** command) and reconfigure it in the following situations:

- You create the ISP domain after specifying it as the preauthentication domain.
- You delete the specified ISP domain and then re-create it.

For the authorization ACL in the preauthentication domain, the following rules apply:

- If the traffic of preauthentication users matches a rule in the ACL, the device processes the traffic based on the permit or deny statement of the rule.
- If the ACL does not exist or the permitted destination address of a rule in the ACL is set to **any**, the device does not control user access. Users can access any network resources without passing portal authentication.
- If the ACL does not have any rules, all user accesses are restricted. The device allows users to access network resources only after they pass authentication.
- If the traffic of preauthentication users does not match any rule in the ACL, the device pushes the authentication page to the users. The users can access the network resources after passing authentication.
- If the ACL contains rules that specify a source address, users might not be able to get online. Do not specify a source IPv4, IPv6 or MAC address when you configure a rule in the ACL.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Specify a portal preauthentication domain.
   portal [**ipv6**] **pre-auth domain** *domain-name*

Specifying a preauthentication IP address pool

About this task

You must specify a preauthentication IP address pool on a portal-enabled interface in the following situation:

- Portal users access the network through a subinterface of the portal-enabled interface.
- The subinterface does not have an IP address.
- Portal users need to obtain IP addresses through DHCP.

After a user connects to a portal-enabled interface, the user uses an IP address for portal authentication according to the following rules:

- If the interface is configured with a preauthentication IP address pool, the user uses the following IP address:
  - If the client is configured to obtain an IP address automatically through DHCP, the user obtains an address from the specified IP address pool.
  - If the client is configured with a static IP address, the user uses the static IP address.
- If the interface has an IP address but no preauthentication IP pool specified, the user uses the static IP address or the IP address obtained from a DHCP server.
- If the interface has no IP address or preauthentication IP pool specified, the user cannot perform portal authentication.

After the user passes portal authentication, the AAA server authorizes an IP address pool for re-assigning an IP address to the user. If no authorized IP address pool is deployed, the user continues using the previous IP address.

Restrictions and guidelines

This configuration takes effect only when the direct IPv4 portal authentication is enabled on the interface.

Make sure the specified IP address pool exists and is complete. Otherwise, the user cannot obtain the IP address and cannot perform portal authentication.

If the portal user does not perform authentication or fails to pass authentication, the assigned IP address is still retained.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Specify a preauthentication IP address pool on the interface.
   portal [**ipv6**] **pre-auth ip-pool** *pool-name*

   By default, no preauthentication IP address pool is specified on an interface.

Specifying a portal authentication domain

About portal authentication domains

An authentication domain defines a set of authentication, authorization, and accounting policies. Each portal user belongs to an authentication domain and is authenticated, authorized, and accounted in the domain.

With an authentication domain specified on an interface, the device uses the authentication domain for AAA of portal users. This allows for flexible portal access control.

Restrictions and guidelines for specifying a portal authentication domain

The device selects the authentication domain for a portal user in this order:

1. ISP domain specified for the interface.
2. ISP domain carried in the username.
3. System default ISP domain.

If the chosen domain does not exist on the device, the device searches for the ISP domain configured to accommodate users assigned to nonexistent domains. If no such ISP domain is configured, user authentication fails. For information about ISP domains, see "Configuring AAA."

For the authorization ACL in the authentication domain, the following rules apply:

- If the user traffic matches a rule in the ACL, the device processes the traffic based on the permit or deny statement of the rule.
- If the user traffic does not match any rule in the ACL, the device permits the traffic. To deny such traffic, configure the last rule in the ACL to deny all packets by using the **rule deny ip** command.
- If the ACL contains rules that specify a source address, users might not be able to get online. Do not specify a source IPv4, IPv6, or MAC address when you configure a rule in the ACL.

Specifying a portal authentication domain on an interface

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Specify an portal authentication domain on the interface.
   portal [**ipv6**] **domain** *domain-name*

   By default, no portal authentication domain is specified on an interface.

   You can specify both an IPv4 portal authentication domain and an IPv6 portal authentication domain on an interface.

Controlling portal user access

Configuring a portal-free rule

About this task

A portal-free rule allows specified users to access specified external websites without portal authentication.

The matching items for a portal-free rule include the host name, source/destination IP address, TCP/UDP port number, source MAC address, microsegment attributes (VPN instance and microsegment ID settings) to which the destination IP address belongs, access interface, and VLAN. Packets matching a portal-free rule will not trigger portal authentication, so users sending the packets can directly access the specified external websites.

Restrictions and guidelines for configuring a portal-free rule

If you specify both a VLAN and an interface, the interface must belong to the VLAN. If the interface does not belong to the VLAN, the portal-free rule does not take effect.

You cannot configure two or more portal-free rules with the same filtering criteria. Otherwise, the system prompts that the rule already exists.

Regardless of whether portal authentication is enabled or not, you can only add or remove a portal-free rule. You cannot modify it.

Before configuring the destination microsegment for a portal-free rule, enable microsegmentation. If a VPN instance is configured for the destination microsegment, make sure the VPN instance has been created. Otherwise, the portal-free rule containing the microsegment does not take effect. To immediately invalidate a portal-free rule containing a microsegment when microsegmentation is disabled, manually delete the portal-free rule. For more information about microsegmentation, see "Configuring microsegmentation."

Configuring an IP-based portal-free rule

1. Enter system view.

   system-view

2. Configure an IP-based portal-free rule.

   IPv4:

   portal free-rule *rule-number* { **destination ip** { *ipv4-address* { *mask-length* | *mask* } | **any** | **microsegment** *microsegment-id* [**vpn-instance** *vpn-instance-name*] } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] | **source ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] } * [**interface** *interface-type interface-number*]

   IPv6:

   portal free-rule *rule-number* { **destination ipv6** { *ipv6-address prefix-length* | **any** | **microsegment** *microsegment-id* [**vpn-instance** *vpn-instance-name*] } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] | **source ipv6** { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] } * [**interface** *interface-type interface-number*]

Configuring a source-based portal-free rule

1. Enter system view.

   system-view

2. Configure a source-based portal-free rule.

portal free-rule *rule-number* **source** { **interface** *interface-type interface-number* | **mac** *mac-address* | **vlan** *vlan-id* } *

The **vlan** *vlan-id* option takes effect only on portal users that access the network through VLAN interfaces.

Configuring a destination-based portal-free rule

1. Enter system view.

   system-view

2. Configure a destination-based portal-free rule.

   portal free-rule *rule-number* **destination** *host-name*

   Before you configure destination-based portal-free rules, make sure a DNS server is deployed on the network.

Configuring an authentication source subnet

About this task

By configuring authentication source subnets, you specify that only HTTP or HTTPS packets from users on the authentication source subnets can trigger portal authentication. HTTP or HTTPS packets from users not in authentication source subnets will be discarded if the packets do not match any portal-free rules.

Restrictions and guidelines

Authentication source subnets are used only for cross-subnet authentication.

In direct or re-DHCP portal authentication mode, a portal user and its access interface (portal-enabled) are on the same subnet. It is not necessary to specify the subnet as the authentication source subnet.

- In direct mode, the access device regards the authentication source subnet as any source IP address.
- In re-DHCP mode, the access device regards the authentication source subnet on an interface as the subnet to which the private IP address of the interface belongs.

If both authentication source subnets and destination subnets are configured on an interface, only the authentication destination subnets take effect.

You can configure multiple authentication source subnets. If the source subnets overlap, the subnet with the largest address scope (with the smallest mask or prefix) takes effect.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Configure a portal authentication source subnet.

   IPv4:

   portal layer3 source *ipv4-network-address* { *mask-length* | *mask* }

   IPv6:

   portal ipv6 layer3 source *ipv6-network-address prefix-length*.

   By default, no portal authentication source subnets are configured, and users from any subnets can trigger portal authentication.

Configuring an authentication destination subnet

About this task

After authentication destination subnets are configured, the device performs portal authentication on portal users only when they access the specified subnets (excluding the destination IP addresses and subnets specified in portal-free rules). Users can access other subnets without portal authentication.

Restrictions and guidelines

If both authentication source subnets and destination subnets are configured on an interface, only the authentication destination subnets take effect.

You can configure multiple authentication destination subnets. If the destination subnets overlap, the subnet with the largest address scope (with the smallest mask or prefix) takes effect.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Configure a portal authentication destination subnet.

   IPv4:

   portal free-all except destination *ipv4-network-address* { *mask-length* | *mask* }

   IPv6:

   portal ipv6 free-all except destination *ipv6-network-address prefix-length*

   By default, no authentication destination subnets are configured, and users accessing any subnets must pass portal authentication.

Configuring support of Web proxy for portal authentication

About this task

To allow HTTP requests proxied by a Web proxy server to trigger portal authentication, specify the port number of the Web proxy server on the device. If a Web proxy server port is not specified on the device, HTTP requests proxied by the Web proxy server are dropped, and portal authentication cannot be triggered.

Restrictions and guidelines

If a user's browser uses the Web Proxy Auto-Discovery (WPAD) protocol to discover Web proxy servers, you must perform the following tasks on the device:

- Specify port numbers of the Web proxy servers.
- Configure portal-free rules to allow user packets destined for the WPAD server to pass without authentication.

If portal users enable Web proxy in their browsers, the users must add the IP address of the portal authentication server as a proxy exception in their browsers. Thus, HTTP packets that the users send to the portal authentication server will not be sent to Web proxy servers.

You cannot specify Web proxy server port 443 on the device.

You can execute this command multiple times to specify multiple port numbers of Web proxy servers.

Procedure

1. Enter system view.
   system-view
2. Specify the port number of a Web proxy server.
   portal web-proxy port *port-number*
   By default, no port numbers of Web proxy servers are specified. Proxied HTTP requests are dropped.

Checking the issuing of category-2 portal filtering rules

About this task

Category-2 portal filtering rules permit authenticated users to access authorized network resources. By default, the device allows an authenticated user to come online as long as a member device has issued a category-2 portal filtering rule for the user. Users coming online from global interfaces might fail to access network resources because some member ports might not have category-2 rules for the users. To resolve this issue, enable the device to check the issuing of category-2 portal filtering rules. Then, the device allows users to come online only when all member devices have issued category-2 portal filtering rules for the users.

As a best practice, perform this task when portal authentication is enabled on a global interface.

Procedure

1. Enter system view.
   system-view
2. Enable the device to check the issuing of category-2 portal filtering rules.
   portal user-rule assign-check enable
   By default, the device does not check the issuing of category-2 portal filtering rules.

Setting the maximum number of portal users

About this task

Perform this task to control the total number of portal users in the system, and the maximum number of IPv4 or IPv6 portal users on an interface.

Restrictions and guidelines for setting the maximum number of portal users

Make sure the maximum combined number of IPv4 and IPv6 portal users specified on all interfaces does not exceed the global maximum number. Otherwise, the exceeding number of portal users will not be able to log in to the device.

Make sure the sum of the maximum number of portal users for IPv4 and IPv6 on an interface does not exceed the maximum number of all portal users set on the interface. Otherwise, the exceeding number of portal users cannot come online from the interface.

You can set the maximum number of portal users in interface view or system view. The maximum number of portal users allowed on an interface is the smallest value among the following items:

- Maximum number of IPv4 or IPv6 portal users allowed on the interface.
- Maximum number of all portal users allowed on the interface.
- Global maximum number of portal users.

Setting the global maximum number of portal users

1. Enter system view.
   system-view

2. Set the global maximum number of portal users.

   portal max-user *max-number*

   By default, no limit is set on the global number of portal users.

   If you set the global maximum number smaller than the number of current online portal users on the device, this configuration still takes effect. The online users are not affected but the system forbids new portal users to log in.

Setting the maximum number of portal users on an interface

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Set the maximum number of portal users.

   portal { **ipv4-max-user** | **ipv6-max-user** | **max-user** } *max-number*

   By default, no limit is set on the number of portal users on an interface.

   If you set the maximum number smaller than the current number of portal users on an interface, this configuration still takes effect. The online users are not affected but the system forbids new portal users to log in from the interface.

Enabling strict-checking on portal authorization information

About this task

The strict checking feature allows a portal user to stay online only when the authorization information for the user is successfully deployed.

Enabling strict checking on portal authentication information on an interface

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Enable strict checking on portal authorization information.

   portal authorization acl strict-checking

CAUTION:

- The device logs out a portal user if the authorized ACL does not exist on the device or fails to be deployed.

By default, strict checking on portal authorization information is disabled on an interface. Portal users stay online even when the authorized ACL does not exist or fails to be deployed.

Allowing only users with DHCP-assigned IP addresses to pass portal authentication

About this task

This feature allows only users with DHCP-assigned IP addresses to pass portal authentication. Use this feature to ensure that only users with valid IP addresses can access the network.

Restrictions and guidelines

This feature takes effect only when the device acts as both the access device and the DHCP server.

Configuration of this feature does not affect the online portal users.

Allowing only users with DHCP-assigned IP addresses to pass portal authentication on an interface

1. Enter system view.

   system-view
2. Enter Layer 3 interface view.

   interface *interface-type interface-number*
3. Allow only users with DHCP-assigned IP addresses to pass portal authentication.

   portal [**ipv6**] **user-dhcp-only**

CAUTION:

- Users with static IP addresses cannot pass portal authentication to come online.
- If this feature is configured, to ensure that IPv6 users can pass portal authentication, disable the temporary IPv6 address feature on terminal devices. Otherwise, IPv6 users will use temporary IPv6 addresses to access the IPv6 network and will fail portal authentication.

By default, both users with IP addresses obtained through DHCP and users with static IP addresses can pass authentication to come online.

Enabling portal roaming

About this task

If portal roaming is enabled on a VLAN interface, an online portal user can access resources from any Layer 2 port in the VLAN without re-authentication.

If portal roaming is disabled, to access external network resources from a Layer 2 port different from the current access port in the VLAN, the user must do the following:

1. Logs out from the current port.
2. Re-authenticates on the new Layer 2 port.

Restrictions and guidelines

Portal roaming takes effect only on portal users logging in from VLAN interfaces. It does not take effect on portal users logging in from common Layer 3 interface.

You cannot enable portal roaming when online portal users or preauthentication portal users exist on the device.

For portal roaming to take effect, you must disable the Rule ARP or ND entry feature by using the **undo portal refresh** { **arp** | **nd** } **enable** command.

Procedure

1. Enter system view.

   system-view
2. Enable portal roaming.

   portal roaming enable

   By default, portal roaming is disabled.

Configuring the portal fail-permit feature

About this task

Perform this task to configure the portal fail-permit feature on an interface. When the access device detects that the portal authentication server or portal Web server is unreachable, it allows users on the interface to have network access without portal authentication.

If you enable fail-permit for both a portal authentication server and a portal Web server on an interface, the interface does the following:

- Disables portal authentication when either server is unreachable.
- Resumes portal authentication when both servers are reachable.

After portal authentication resumes, unauthenticated users must pass portal authentication to access the network. Users who have passed portal authentication before the fail-permit event can continue accessing the network.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Enable portal fail-permit for a portal authentication server.
   portal [**ipv6**] **fail-permit server** *server-name*
   By default, portal fail-permit is disabled for a portal authentication server.
4. Enable portal fail-permit for portal Web servers.
   portal [**ipv6**] **fail-permit web-server**
   By default, portal fail-permit is disabled for portal Web servers.

Specifying a critical profile on an interface and setting the aging time for portal users in critical microsegments

About this task

In direct portal authentication mode, when no authentication server is reachable, the portal critical microsegment feature allows users to access network resources in microsegments of the critical profiles specified on the access interfaces without performing authentication.

After you specify a critical profile on an interface for portal authentication, the critical profile is assigned to the users on the interface when all authentication servers are unreachable. The users then can access network resources in the critical profile, such as the critical microsegment. For users in a VPN instance, the users can access the critical microsegment specified for the VPN instance. If no critical microsegment is specified for the VPN instance, the users can access the default critical microsegment.

Portal users in critical microsegments have an aging time. Aged portal users in critical microsegments are logged out to avoid occupying too much system resources. Set a proper aging time for portal users in critical microsegments according to your network condition.

Restrictions and guidelines

Before specifying a critical profile for an access interface of portal users, make sure microsegmentation is enabled. The critical profile specified for the interface must be configured correctly. For more information about configuring critical profiles, see "Configuring AAA."

In a portal dual-stack network, the microsegment attribute used by the second stack is restricted by the microsegment attribute obtained from the critical profile of the first stack.

Some features such as online detection do not take effect on portal users in critical microsegments. Modification of critical profile configurations causes online portal users in critical microsegments to go offline.

Procedure

1. Enter system view.
   system-view
2. Configure the aging time for portal users in critical microsegments.
   portal critical-microsegment aging-time *minutes*
   By default, the aging time for portal users in critical microsegments is 10 minutes.
3. Enter Layer 3 interface view.
   interface *interface-type interface-number*
4. Specify a critical profile for portal users on the interface.
   portal [**ipv6**] **critical profile** *profile-name*
   By default, no critical profile for portal users is specified on an interface.

Configuring portal detection features

Configuring online detection of portal users

About this task

Use the online detection feature to quickly detect abnormal logouts of portal users. Configure ARP or ICMP detection for IPv4 portal users. Configure ND or ICMPv6 detection for IPv6 portal users.

If the device receives no packets from a portal user within the idle time, the device detects the user's online status as follows:

- **ICMP or ICMPv6 detection**—Sends ICMP or ICMPv6 requests to the user at configurable intervals to detect the user status.
  - If the device receives a reply within the maximum number of detection attempts, it considers that the user is online and stops sending detection packets. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the device receives no reply after the maximum number of detection attempts, the device logs out the user.
- **ARP or ND detection**—Sends ARP or ND requests to the user and detects the ARP or ND entry status of the user at configurable intervals.
  - If the ARP or ND entry of the user is refreshed within the maximum number of detection attempts, the device considers that the user is online and stops detection. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the ARP or ND entry of the user is not refreshed after the maximum number of detection attempts, the device logs out the user.

Restrictions and guidelines

ARP detection and ND detection apply only to direct and re-DHCP portal authentication. ICMP detection applies to all portal authentication modes.

Procedure

1. Enter system view.
   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Configure online detection of portal users.

   IPv4:

   portal user-detect type { **arp** | **icmp** } [**retry** *retries*] [**interval** *interval*] [**idle** *time*]

   IPv6:

   portal ipv6 user-detect type { **icmpv6** | **nd** } [**retry** *retries*] [**interval** *interval*] [**idle** *time*]

   By default, online detection is disabled for portal users on an interface.

Configuring portal authentication server detection

About this task

During portal authentication, if the communication between the access device and portal authentication server is broken, new portal users are not able to log in. Online portal users are not able to log out normally.

To address this problem, the access device needs to be able to detect the reachability changes of the portal server quickly and take corresponding actions to deal with the changes.

The portal authentication server detection feature enables the device to periodically detect portal packets sent by a portal authentication server to determine the reachability of the server. If the device receives a portal packet within a detection timeout (**timeout** *timeout*) and the portal packet is valid, the device considers the portal authentication server to be reachable. Otherwise, the device considers the portal authentication server to be unreachable.

Portal packets include user login packets, user logout packets, and heartbeat packets. Heartbeat packets are periodically sent by a server. By detecting heartbeat packets, the device can detect the server's actual status more quickly than by detecting other portal packets.

Restrictions and guidelines

The portal authentication server detection feature takes effect only when the device has a portal-enabled interface.

Only the IMC portal authentication server supports sending heartbeat packets. To test server reachability by detecting heartbeat packets, you must enable the server heartbeat feature on the IMC portal authentication server.

You can configure the device to take one or more of the following actions when the server reachability status changes:

- Sending a log message, which contains the name, the current state, and the original state of the portal authentication server.
- Enabling portal fail-permit. When the portal authentication server is unreachable, the portal fail-permit feature on an interface allows users on the interface to have network access. When the server recovers, it resumes portal authentication on the interface. For more information, see "Configuring the portal fail-permit feature."
- Make sure the detection timeout configured on the device is greater than the server heartbeat interval configured on the portal authentication server.

Procedure

1. Enter system view.

   system-view

2. Enter portal authentication server view.

portal server *server-name*

3. Configure portal authentication server detection.

   server-detect [**timeout** *timeout*] **log**

   By default, portal authentication server detection is disabled.

Configuring portal Web server detection

About this task

A portal authentication process cannot complete if the communication between the access device and the portal Web server is broken. To address this problem, you can enable portal Web server detection on the access device.

With the portal Web server detection feature, the access device simulates a Web access process to initiate a TCP connection to the portal Web server. If the TCP connection can be established successfully, the access device considers the detection successful, and the portal Web server is reachable. Otherwise, it considers the detection to have failed.

You can configure the following detection parameters:

- **Detection interval**—Interval at which the device detects the server reachability.
- **Maximum number of consecutive failures**—If the number of consecutive detection failures reaches this value, the access device considers that the portal Web server is unreachable.

You can configure the device to take one or more of the following actions when the server reachability status changes:

- Sending a log message, which contains the name, the current state, and the original state of the portal Web server.
- Enabling portal fail-permit. When the portal Web server is unreachable, the portal fail-permit feature on an interface allows users on the interface to have network access. When the server recovers, it resumes portal authentication on the interface. For more information, see "Configuring the portal fail-permit feature."

Restrictions and guidelines

The portal Web server detection feature takes effect only when the URL of the portal Web server is specified and the device has a portal-enabled interface.

Procedure

1. Enter system view.

   system-view

2. Enter portal Web server view.

   portal web-server *server-name*

3. Configure portal Web server detection.

   server-detect [**interval** *interval*] [**retry** *retries*] **log**

   By default, portal Web server detection is disabled.

Configuring portal user synchronization

About this task

Once the access device loses communication with a portal authentication server, the portal user information on the access device and that on the portal authentication server might be inconsistent after the communication resumes. To address this problem, the device provides the portal user synchronization feature. This feature is implemented by sending and detecting portal synchronization packets, as follows:

1. The portal authentication server sends the online user information to the access device in a synchronization packet at the user heartbeat interval.

   The user heartbeat interval is set on the portal authentication server.

2. Upon receiving the synchronization packet, the access device compares the users carried in the packet with its own user list and performs the following operations:
   - If a user contained in the packet does not exist on the access device, the access device informs the portal authentication server to delete the user. The access device starts the synchronization detection timer (**timeout** *timeout*) immediately when a user logs in.
   - If the user does not appear in any synchronization packet within a synchronization detection interval, the access device considers the user does not exist on the portal authentication server and logs the user out.

Restrictions and guidelines

Portal user synchronization requires a portal authentication server to support the portal user heartbeat function. Only the IMC portal authentication server supports the portal user heartbeat function. To implement the portal user synchronization feature, you also need to configure the user heartbeat function on the portal authentication server. Make sure the user heartbeat interval configured on the portal authentication server is not greater than the synchronization detection timeout configured on the access device.

Deleting a portal authentication server on the access device also deletes the user synchronization configuration for the portal authentication server.

Procedure

1. Enter system view.

   system-view

2. Enter portal authentication server view.

   portal server *server-name*

3. Configure portal user synchronization.

   user-sync timeout *timeout*

   By default, portal user synchronization is disabled.

Configuring portal packet attributes

Configuring the BAS-IP or BAS-IPv6 attribute

About this task

If the device runs Portal 2.0, the unsolicited packets sent to the portal authentication server must carry the BAS-IP attribute. If the device runs Portal 3.0, the unsolicited packets sent to the portal authentication server must carry the BAS-IP or BAS-IPv6 attribute.

After this attribute is configured, the source IP address for unsolicited notification portal packets the device sends to the portal authentication server is the configured BAS-IP or BAS-IPv6 address. If the attribute is not configured, the source IP address of the portal packets is the IP address of the packet output interface.

Restrictions and guidelines

During a re-DHCP portal authentication or mandatory user logout process, the device sends portal notification packets to the portal authentication server. For the authentication or logout process to complete, make sure the BAS-IP/BAS-IPv6 attribute is the same as the device IP address specified on the portal authentication server.

You must configure the BAS-IP or BAS-IPv6 attribute on a portal authentication-enabled interface if the following conditions are met:

- The portal authentication server is an IMC server.
- The portal device IP address specified on the portal authentication server is not the IP address of the portal packet output interface.

Configuring the BAS-IP or BAS-IPv6 attribute on an interface

1. Enter system view.

   system-view
2. Enter Layer 3 interface view.

   interface *interface-type interface-number*
3. Configure the BAS-IP or BAS-IPv6 attribute.

   IPv4:

   portal bas-ip *ipv4-address*

   By default, the BAS-IP attribute of an IPv4 portal reply packet is the source IPv4 address of the packet. The BAS-IP attribute of an IPv4 portal notification packet is the IPv4 address of the packet's output interface.

   IPv6:

   portal bas-ipv6 *ipv6-address*

   By default, the BAS-IPv6 attribute of an IPv6 portal reply packet is the source IPv6 address of the packet. The BAS-IPv6 attribute of an IPv6 portal notification packet is the IPv6 address of the packet's output interface.

Specifying the device ID

About this task

The portal authentication server uses device IDs to identify the devices that send protocol packets to the portal server.

Restrictions and guidelines

Make sure the configured device ID is different than any other access devices communicating with the same portal authentication server.

Procedure

1. Enter system view.

   system-view
2. Specify the device ID.

   portal device-id *device-id*

   By default, a device is not configured with a device ID.

Configuring attributes for RADIUS packets

Specifying a format for the NAS-Port-Id attribute

About this task

RADIUS servers from different vendors might require different formats of the NAS-Port-Id attribute in the RADIUS packets. You can specify the NAS-Port-Id attribute format as required.

The device supports predefined formats (format 1, 2, 3, and 4). For more information about the formats, see portal commands in *Security Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Specify the format for the NAS-Port-Id attribute.

   portal nas-port-id format { **1** | **2** | **3** | **4** }

   By default, the format for the NAS-Port-Id attribute is format 2.

Configuring the NAS-Port-Type attribute

About this task

The NAS-Port-Type attribute in a RADIUS request represents the type of a user's access interface.

The access device might not be able to correctly obtain the type of users' access interfaces when multiple network devices exist between the access device and the portal client. For the access device to send the correct access interface type to the RADIUS server, perform this task to configure the NAS-Port-Type attribute.

Restrictions and guidelines

This configuration takes effect only on portal users that newly come online.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Configure the NAS-Port-Type attribute carried in outgoing RADIUS requests on the interface.

   portal nas-port-type { **802.11** | **adsl-cap** | **adsl-dmt** | **async** | **cable** | **ethernet** | **g.3-fax** | **hdlc** | **idsl** | **isdn-async-v110** | **isdn-async-v120** | **isdn-sync** | **piafs** | **sdsl** | **sync** | **virtual** | **wireless-other** | **x.25** | **x.75** | **xdsl** }

   By default, the NAS-Port-Type carried in outgoing RADIUS requests is Ethernet (attribute value 15).

Applying a NAS-ID profile to an interface

About this task

By default, the device sends its device name in the NAS-Identifier attribute of all RADIUS requests.

A NAS-ID profile enables you to send different NAS-Identifier attribute strings in RADIUS requests from different VLANs. The strings can be organization names, service names, or any user categorization criteria, depending on the administrative requirements.

For example, map the NAS-ID **companyA** to all VLANs of company A. The device will send **companyA** in the NAS-Identifier attribute for the RADIUS server to identify requests from any Company A users.

Restrictions and guidelines

You can apply a NAS-ID profile to a portal-enabled interface. If no NAS-ID profile is specified on the interface or no matching NAS-ID is found in the specified profile, the device uses the device name as the interface NAS-ID.

Procedure

1. Enter system view.
   system-view
2. Create a NAS-ID profile and enter NAS-ID profile view.
   aaa nas-id profile *profile-name*
   For more information about this command, see *Security Command Reference*.
3. Configure a NAS ID and VLAN binding in the profile.
   nas-id *nas-identifier* **bind vlan** *vlan-id*
   For more information about this command, see *Security Command Reference*. Portal access matches only the inner VLAN ID of QinQ packets. For more information about QinQ, see *Layer 2—LAN Switching Configuration Guide*.
4. Specify the NAS-ID profile on the interface.
   a. Return to system view.
      quit
   b. Enter Layer 3 interface view.
      interface *interface-type interface-number*
   c. Specify the NAS-ID profile on the interface.
      portal nas-id-profile *profile-name*
      By default, no NAS-ID profile is specified for an interface.

Configuring MAC-based quick portal authentication

Restrictions and guidelines for configuring MAC-based quick portal authentication

Only direct portal authentication supports MAC-based quick portal authentication.

For MAC-based quick portal authentication to take effect on an interface configured with a portal preauthentication policy, set the free-traffic threshold to 0 bytes.

Configuring a MAC binding server

About this task

You can configure multiple MAC binding servers on the device.

Perform this task to configure MAC binding server parameters, such as the server's IP address, VPN instance, port number, and the pre-shared key for communication between the access device and the server.

Procedure

1. Enter system view.
   system-view
2. Create a MAC binding server and enter its view.
   portal mac-trigger-server *server-name*
   By default, no MAC binder servers exist.

3. Configure a MAC binding server.
   - Specify the IP address of the MAC binding server.

     IPv4:

     ip *ipv4-address* [**vpn-instance** *vpn-instance-name*] [**key** { **cipher** | **simple** } *string*]

     IPv6:

     ipv6 *ipv6-address* [**vpn-instance** *vpn-instance-name*] [**key** { **cipher** | **simple** } *string*]

     By default, no MAC binding server address is specified.
   - (Optional.) Set the UDP port number on which the MAC binding server listens for MAC binding query packets.

     port *port-number*

     By default, the MAC binding server listens for MAC binding query packets on UDP port 50100.
   - (Optional.) Set the maximum number of attempts and the interval for sending MAC binding queries to the MAC binding server.

     binding-retry { *retries* | **interval** *interval* } *

     By default, the maximum number of query attempts is 3 and the query interval is 1 second.
   - (Optional.) Specify the type of the MAC binding server.

     server-type { **cmcc** | **imc** }

     By default, the type of a MAC binding server is IMC.
4. (Optional.) Set the free-traffic threshold.

   free-traffic threshold *value*

   By default, the free-traffic threshold is 0 bytes.
5. (Optional.) Set the NAS-Port-Type value carried in RADIUS requests sent to the RADIUS server.

   nas-port-type *value*

   By default, the NAS-Port-Type value carried in RADIUS requests is 0.
6. (Optional.) Specify the version of the portal protocol.

   version *version-number*

   By default, the version of the portal protocol is 1.
7. (Optional.) Set the timeout the device waits for portal authentication to complete after receiving the MAC binding query response.

   authentication-timeout *minutes*

   By default, the portal authentication timeout time is 3 minutes.
8. (Optional.) Set the aging time for MAC-trigger entries.

   aging-time *seconds*

   By default, the aging time for MAC-trigger entries is 300 seconds.

Specifying a MAC binding server on an interface

About this task

After a MAC binding server is specified on an interface, the device can implement MAC-based quick portal authentication for portal users on the interface.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Specify a MAC binding server on the interface.
   portal [**ipv6**] **apply mac-trigger-server** *server-name*
   By default, no MAC binding server is specified on an interface.

Configuring cloud MAC-trigger authentication

About this task

This feature enables the cloud portal server to act as a MAC binding server to perform cloud MAC-trigger authentication on portal users.

Procedure

1. Enter system view.
   system-view
2. Create a MAC binding server and enter its view.
   portal mac-trigger-server *server-name*
3. Enable cloud MAC-trigger authentication.
   cloud-binding enable
   By default, cloud MAC-trigger authentication is disabled.
4. Specify the URL of the cloud portal authentication server.
   cloud-server url *url-string*
   By default, the cloud portal authentication server URL is not specified. The device uses the URL of the portal Web server as the URL of the cloud portal authentication server.

Configuring IP-based quick portal authentication

Prerequisites

Before configuring IP-based quick portal authentication on the device, configure user accounts on the RADIUS server for IP-trigger authentication. Each of the accounts uses the user's IP address as both the username and password.

Restrictions and guidelines

Only direct authentication and cross-subnet authentication support IP-based quick portal authentication.

If both IP-based and MAC-based quick portal authentication modes are enabled on an interface, the MAC-based mode has a higher priority. The device will perform MAC-based quick portal authentication for a user if it can obtain both the MAC address and IP address of the user.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*

3. Configure IP-based quick portal authentication.

   IPv4:

   portal enable method { **direct** | **layer3** } [**ip-trigger** [**acl** *acl-number*]]

   IPv6:

   portal ipv6 enable method { **direct** | **layer3** } [**ip-trigger** [**acl** *acl-number*]]

   By default, IP-based quick portal authentication is disabled.

4. (Optional.) Configure the IP-trigger entry aging time.

   portal ip-trigger aging-time *seconds*

   By default, the IP-trigger entry aging time is 300 seconds.

Configuring portal authentication to support M-LAG

Prerequisites

Before you configure portal authentication to support M-LAG, you must complete the following tasks on both the primary and secondary M-LAG member devices:

- Enable portal authentication.
- Configure IPv4 portal authentication or IPv6 portal authentication.
- Set the portal authentication mode.
- Enable or disable MAC-based quick portal authentication.
- Set the free-traffic threshold.
- Enable portal fail-permit for a portal authentication server.
- Configure the URL of the portal Web server.
- Configure portal user roaming.
- Enable or disable portal authentication to support IPv4/IPv6 dual stack.

Make sure the above configuration on both the primary and secondary M-LAG member devices are the same.

Setting the authentication load sharing mode for portal users on M-LAG interfaces

About this task

By default, the primary M-LAG member device authenticates portal users on all M-LAG interfaces in an M-LAG system. If a large number of portal users exist, perform this task to set the authentication load sharing mode to improve authentication efficiency.

Restrictions and guidelines

Do not set the same distribution criterion for the distributed authentication load sharing mode on both the M-LAG member devices. A violation might cause that portal users fail to come online.

If online portal users already exist on the M-LAG network, do not change the authentication load sharing mode.

Procedure

1. Enter system view.

   system-view

2. Set the authentication load sharing mode for portal users on M-LAG interfaces.

   portal m-lag load-sharing-mode { **centralized** | **distributed** { **even-ip** | **odd-ip** } }

   By default, the authentication load sharing mode is centralized for portal users on M-LAG interfaces.

Configure traffic backup for portal users on M-LAG interfaces

About this task

In an M-LAG system, the M-LAG member devices synchronize traffic of portal users with each other. A M-LAG member device can periodically back up traffic of portal users to the peer device at the specified interval. It can also back up portal user traffic to the peer device if the amount of incremental traffic it has received since the last backup reaches the backup threshold.

Perform this task to decrease the frequency of traffic backup among M-LAG member devices.

Procedure

1. Enter system view.

   system-view

2. Set the traffic backup interval and threshold for portal users on M-LAG interfaces.

   portal m-lag traffic backup { **interval** *interval-value* | **threshold** *threshold-value* } *

   By default, the traffic backup interval is 10 minutes and the traffic backup threshold is 50 MB for portal users on M-LAG interfaces.

Logging out online portal users

About this task

This feature deletes users that have passed portal authentication and terminates ongoing portal authentications.

Restrictions and guidelines

When the number of online users exceeds 2000, executing the **portal delete-user** command takes a few minutes.

To ensure successful logout of online users, do not disable portal authentication or perform master/subordinate device switchover on the portal-enabled interface during the command execution.

Procedure

1. Enter system view.

   system-view

2. Log out online portal users.

   portal delete-user { *ipv4-address* | **all** | **auth-type** { **cloud** | **local** | **normal** } | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* | **mac** *mac-address* }

Enabling portal user login/logout logging

About this task

This feature logs information about user login and logout events. The information includes the username, user IP address and MAC address, user access interface, VLAN, and login result. The logs are sent to the information center of the device. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Enable portal user login/logout logging.
   `portal log enable`
   By default, portal user login/logout logging is disabled.

Disabling the Rule ARP or ND entry feature for portal clients

About this task

When the Rule ARP or ND entry feature is enabled for portal clients, ARP or ND entries for portal clients are Rule entries after the clients come online. After the portal clients go offline, the Rule ARP or ND entries are converted into dynamic entries and deleted when they age out.

Restrictions and guidelines

Enabling or disabling of this feature does not affect existing Rule/dynamic ARP or ND entries.

If the portal clients and the portal server belong to different VPNs, the Rule ARP entry feature will cause the portal clients to go offline abnormally. To avoid this issue, execute the **`undo portal refresh arp enable`** command to disable the Rule ARP entry feature for portal clients.

Procedure

1. Enter system view.
   `system-view`
2. Disable the Rule ARP or ND entry feature for portal clients.
   `undo portal refresh` { **`arp`** | **`nd`** } **`enable`**
   By default, the Rule ARP or ND entry feature is enabled for portal clients.

Configuring Web redirect

About this task

Web redirect is a simplified portal feature. With Web redirect, a user does not perform portal authentication but is directly redirected to the specified URL on the first Web access attempt in a browser. After the specified redirect interval, the user is redirected from the visiting website to the specified URL again.

Web redirect can provide ISPs with extended services. For example, the ISPs can place advertisements and publish information on the redirected webpage.

Restrictions and guidelines

The Web redirect feature takes effect only on HTTP packets that use the default port number 80.

If the device supports Etherchannel interfaces, you can enable both Web redirect and portal authentication on interfaces that support these features. If the device does not support Etherchannel interfaces, Web redirect does not work when both Web redirect and portal authentication are enabled on an interface.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Configure Web redirect.
   web-redirect [**ipv6**] **url** *url-string* [**interval** *interval*]
   By default, Web redirect is disabled.

Setting the user synchronization interval for portal authentication using OAuth

About this task

If portal authentication uses OAuth, the device periodically reports user information to the portal authentication server for user synchronization on the server. To disable user synchronization from the device to the portal authentication server, set the user synchronization interval to 0 seconds on the device.

Procedure

1. Enter system view.
   system-view
2. Set the user synchronization interval for portal authentication using OAuth.
   portal oauth user-sync interval *interval*
   By default, the user synchronization interval is 60 seconds.

Obtaining user access information from ARP or ND entries

About this task

In a remote Web authentication network, the device cannot obtain user access information from FIB entries upon receiving portal packets from the portal authentication server. This will cause users to fail Web authentication.

To resolve this issue, you can perform this task on the device. When this feature is enabled, the device first attempts to obtain user access information from ARP or ND entries during Web authentication.

Procedure

1. Enter system view.
   system-view

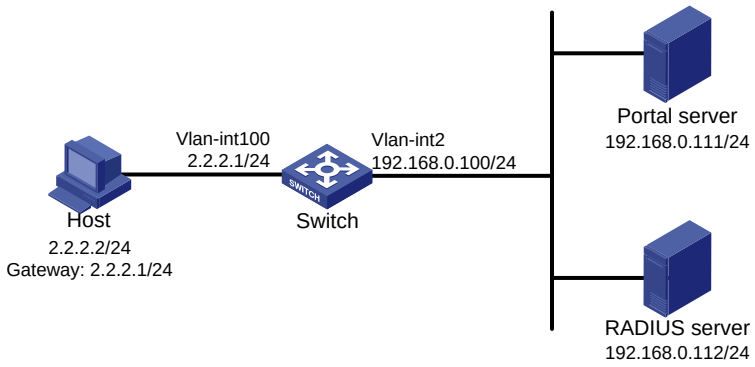
2. Configure the device to obtain user information from ARP or ND entries.
   portal access-info trust { **arp** | **nd** }
   By default, the device obtains user information from FIB entries.

Display and maintenance commands for portal

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display portal configuration and portal running state.	**display portal interface** *interface-type interface-number*
Display packet statistics for portal captive-bypass.	**display portal captive-bypass statistics** [**slot** *slot-number*]
Display information about MAC binding servers.	**display portal mac-trigger-server** { **all** | **name** *server-name* }
Display packet statistics for portal authentication servers.	**display portal packet statistics** [**extend-auth-server cloud** | **server** *server-name*]
Display portal rules.	**display portal rule** { **all** | **dynamic** | **static** } **interface** *interface-type interface-number* [**slot** *slot-number*]
Display portal authentication server information.	**display portal server** [*server-name*]
Display session information for portal users or portal-based Web authentication users.	**display portal session user-type** { **portal** | **web-auth** }
Display portal user information.	**display portal user** { **all** | **auth-type** { **cloud** | **local** | **normal** } | **interface** *interface-type interface-number* | **ip** *ipv4-address* | **ipv6** *ipv6-address* | **mac** *mac-address* | **pre-auth** [**interface** *interface-type interface-number* | **ip** *ipv4-address* | **ipv6** *ipv6-address*] | **username** *username* } [**brief** | **verbose**]
Display portal Web server information.	**display portal web-server** [*server-name*]
Display Web redirect rule information.	**display web-redirect rule interface** *interface-type interface-number* [**slot** *slot-number*]
Clear packet statistics for portal captive-bypass.	**reset portal captive-bypass statistics** [**slot** *slot-number*]
Clear packet statistics for portal authentication servers.	**reset portal packet statistics** [**extend-auth-server cloud** | **server** *server-name*]

Portal configuration examples



Example: Configuring direct portal authentication

Network configuration

As shown in Figure 7, the host is directly connected to the switch (the access device). The host is assigned a public IP address either manually or through DHCP. An IMC server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure direct portal authentication, so the host can access only the portal server before passing the authentication and access other network resources after passing the authentication.

Figure 7 Network diagram

Prerequisites

- Configure IP addresses for the host, switch, and servers and make sure they can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.
- Configure the portal service on the IMC server, including setting portal server parameters, adding access devices, creating user IP address groups, and configuring device port groups to associate with IP address groups. This ensures coordinated implementation of portal authentication with the device.

Configuring the switch

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<Switch> system-view
[Switch] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 192.168.0.112
[Switch-radius-rs1] primary accounting 192.168.0.112
[Switch-radius-rs1] key authentication simple radius
[Switch-radius-rs1] key accounting simple radius
```

Exclude the ISP domain name from the username sent to the RADIUS server.

```
[Switch-radius-rs1] user-name-format without-domain
[Switch-radius-rs1] quit
```

Enable RADIUS session control.

```
[Switch] radius session-control enable
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure portal authentication:

Configure a portal authentication server.

```
[Switch] portal server newpt
[Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
[Switch-portal-server-newpt] port 50100
[Switch-portal-server-newpt] quit
```

Configure a portal Web server.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Switch-portal-websvr-newpt] quit
```

Enable direct portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal enable method direct
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
```

Configure the BAS-IP as 2.2.2.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

```
[Switch–Vlan-interface100] portal bas-ip 2.2.2.1
[Switch–Vlan-interface100] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[Switch] display portal interface vlan-interface 100
 Portal information of Vlan-interface100
     NAS-ID profile: Not configured
     M-LAG group ID: N/A
     M-LAG role    : N/A
     Authorization : Strict checking
     ACL           : Disabled
     User profile  : Disabled
     Max users     : Not configured
 IPv4:
     Portal status: Enabled
     Portal authentication method: Direct    authentication shared mode: Disabled
     Portal web server: newpt(active)
```

```
     Secondary portal Web server: Not configured
     Portal mac-trigger-server: Not configured
     Authentication domain: Not configured
     Pre-auth domain: Not configured
     User-dhcp-only: Disabled
     Pre-auth IP pool: Not configured
     Max users: Not configured
     Bas-ip: 2.2.2.1
     User detection:  Not configured
     Action for server detection:
         Server type    Server name                         Action
         --             --                                  --
     Layer3 source network:
         IP address              Mask

     Destination authenticate subnet:
         IP address              Mask
IPv6:
     Portal status: Disabled
     Portal authentication method: Disabled    authentication shared mode: Disabled
     Portal web server: Not configured
     Secondary portal Web server: Not configured
     Portal mac-trigger-server: Not configured
     Authentication domain: Not configured
     Pre-auth domain: Not configured
     User-dhcp-only: Disabled
     Pre-auth IP pool: Not configured
     Max users: Not configured
     Bas-ipv6: Not configured
     User detection: Not configured
     Action for server detection:
         Server type    Server name                         Action
         --             --                                  --
     Layer3 source network:
         IP address                                         Prefix length

     Destination authenticate subnet:
         IP address                                         Prefix length
```

A user can perform portal authentication by using the iNode client or through a Web browser. Before passing the authentication, the user can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page. After passing the authentication, the user can access other network resources.

After the user passes authentication, use the following command to display information about the portal user.

```
[Switch] display portal user interface vlan-interface 100
 Total portal users: 1
  Username: abc
  Portal server: newpt
  State: Online
```

```
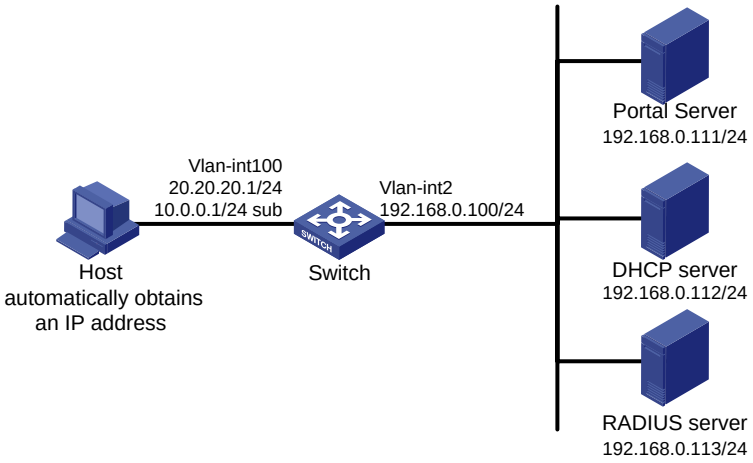
VPN instance: N/A
MAC               IP              VLAN   Interface
0015-e9a6-7cfe    2.2.2.2         100    Vlan-interface100
Authorization information:
  DHCP IP pool: N/A
  User profile: N/A
  Session group profile: N/A
  ACL number: N/A
  Inbound CAR: N/A
  Outbound CAR: N/A
  Microsegment ID: N/A
```



Example: Configuring re-DHCP portal authentication

Network configuration

As shown in Figure 8, the host is directly connected to the switch (the access device). The host obtains an IP address through the DHCP server. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure re-DHCP portal authentication. Before passing the authentication, the host is assigned a private IP address. After passing the authentication, the host gets a public IP address and can access network resources.

Figure 8 Network diagram

Restrictions and guidelines

- For re-DHCP portal authentication, configure a public address pool (20.20.20.0/24) and a private address pool (10.0.0.0/24) on the DHCP server. (Details not shown.)
- For re-DHCP portal authentication:
  - The switch must be configured as a DHCP relay agent.
  - The portal-enabled interface must be configured with a primary IP address (a public IP address) and a secondary IP address (a private IP address).

  For information about DHCP relay agent configuration, see *Layer 3—IP Services Configuration Guide*.
- Make sure the IP address of the portal device added on the portal server is the public IP address (20.20.20.1) of the switch's interface connecting the host. The private IP address range for the IP address group associated with the portal device is the private subnet 10.0.0.0/24

where the host resides. The public IP address range for the IP address group is the public subnet 20.20.20.0/24.

Prerequisites

- Configure IP addresses for the switch and servers as shown in Figure 8 and make sure the host, switch, and servers can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1** and enter its view.

   ```
   <Switch> system-view
   [Switch] radius scheme rs1
   ```

   # Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

   ```
   [Switch-radius-rs1] primary authentication 192.168.0.113
   [Switch-radius-rs1] primary accounting 192.168.0.113
   [Switch-radius-rs1] key authentication simple radius
   [Switch-radius-rs1] key accounting simple radius
   ```

   # Exclude the ISP domain name from the username sent to the RADIUS server.

   ```
   [Switch-radius-rs1] user-name-format without-domain
   [Switch-radius-rs1] quit
   ```

   # Enable RADIUS session control.

   ```
   [Switch] radius session-control enable
   ```

2. Configure an authentication domain:

   # Create an ISP domain named **dm1** and enter its view.

   ```
   [Switch] domain dm1
   ```

   # Configure AAA methods for the ISP domain.

   ```
   [Switch-isp-dm1] authentication portal radius-scheme rs1
   [Switch-isp-dm1] authorization portal radius-scheme rs1
   [Switch-isp-dm1] accounting portal radius-scheme rs1
   [Switch-isp-dm1] quit
   ```

   # Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

   ```
   [Switch] domain default enable dm1
   ```

3. Configure DHCP relay and authorized ARP:

   # Configure DHCP relay.

   ```
   [Switch] dhcp enable
   [Switch] dhcp relay client-information record
   [Switch] interface vlan-interface 100
   [Switch–Vlan-interface100] ip address 20.20.20.1 255.255.255.0
   [Switch–Vlan-interface100] ip address 10.0.0.1 255.255.255.0 sub
   [Switch-Vlan-interface100] dhcp select relay
   [Switch-Vlan-interface100] dhcp relay server-address 192.168.0.112
   ```

   # Enable authorized ARP.

   ```
   [Switch-Vlan-interface100] arp authorized enable
   [Switch-Vlan-interface100] quit
   ```

4. Configure portal authentication:

Configure a portal authentication server.

```
[Switch] portal server newpt
[Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
[Switch-portal-server-newpt] port 50100
[Switch-portal-server-newpt] quit
```

Configure a portal Web server.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Switch-portal-websvr-newpt] quit
```

Enable re-DHCP portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal enable method redhcp
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
```

Configure the BAS-IP as 20.20.20.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

```
[Switch–Vlan-interface100] portal bas-ip 20.20.20.1
[Switch–Vlan-interface100] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[Switch] display portal interface vlan-interface 100
 Portal information of Vlan-interface100
     NAS-ID profile: Not configured
     M-LAG group ID: N/A
     M-LAG role    : N/A
     Authorization : Strict checking
     ACL           : Disabled
     User profile  : Disabled
     Max users     : Not configured

     Pre-auth domain: Not configured
     User-dhcp-only: Disabled
     Pre-auth IP pool: Not configured
     Max users: Not configured
     Bas-ip: 20.20.20.1
     User detection:  Not configured
     Action for server detection:
         Server type    Server name                          Action
         --             --                                   --
     Layer3 source network:
         IP address              Mask
```

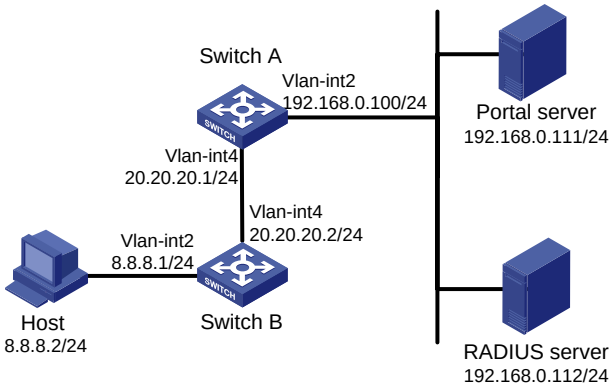
```
     Destination authenticate subnet:
         IP address              Mask
IPv6:
     Portal status: Disabled
     Portal authentication method: Disabled    authentication shared mode: Disabled
     Portal web server: Not configured
     Secondary portal Web server: Not configured
     Portal mac-trigger-server: Not configured
     Authentication domain: Not configured
     Pre-auth domain: Not configured
     User-dhcp-only: Disabled
     Pre-auth IP pool: Not configured
     Max users: Not configured
     Bas-ipv6: Not configured
     User detection: Not configured
     Action for server detection:
         Server type    Server name                        Action
         --             --                                 --
     Layer3 source network:
         IP address                                        Prefix length

     Destination authenticate subnet:
         IP address                                        Prefix length
```

Before passing the authentication, a user that uses the iNode client can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page. After passing the authentication, the user can access other network resources.

After the user passes authentication, use the following command to display information about the portal user.

```
[Switch] display portal user interface vlan-interface 100
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  0015-e9a6-7cfe    20.20.20.2        100    Vlan-interface100
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
    Microsegment ID: N/A
```



Example: Configuring cross-subnet portal authentication

Network configuration

As shown in Figure 9, Switch A supports portal authentication. The host accesses Switch A through Switch B. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure Switch A for cross-subnet portal authentication. Before passing the authentication, the host can access only the portal Web server. After passing the authentication, the user can access other network resources.

Figure 9 Network diagram

Restrictions and guidelines

Make sure the IP address of the portal device added on the portal authentication server is the IP address (20.20.20.1) of the switch's interface connecting the host. The IP address group associated with the portal device is the subnet of the host (8.8.8.0/24).

Prerequisites

- Configure IP addresses for the switch and servers as shown in Figure 9 and make sure the host, switch, and servers can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<SwitchA> system-view
[SwitchA] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[SwitchA-radius-rs1] primary authentication 192.168.0.112
[SwitchA-radius-rs1] primary accounting 192.168.0.112
[SwitchA-radius-rs1] key authentication simple radius
[SwitchA-radius-rs1] key accounting simple radius
```

Exclude the ISP domain name from the username sent to the RADIUS server.

```
[SwitchA-radius-rs1] user-name-format without-domain
[SwitchA-radius-rs1] quit
```

Enable RADIUS session control.

```
[SwitchA] radius session-control enable
```

2. Configure an authentication domain:

   # Create an ISP domain named **dm1** and enter its view.

   ```
   [SwitchA] domain dm1
   ```

   # Configure AAA methods for the ISP domain.

   ```
   [SwitchA-isp-dm1] authentication portal radius-scheme rs1
   [SwitchA-isp-dm1] authorization portal radius-scheme rs1
   [SwitchA-isp-dm1] accounting portal radius-scheme rs1
   [SwitchA-isp-dm1] quit
   ```

   # Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

   ```
   [SwitchA] domain default enable dm1
   ```

3. Configure portal authentication:

   # Configure a portal authentication server.

   ```
   [SwitchA] portal server newpt
   [SwitchA-portal-server-newpt] ip 192.168.0.111 key simple portal
   [SwitchA-portal-server-newpt] port 50100
   [SwitchA-portal-server-newpt] quit
   ```

   # Configure a portal Web server.

   ```
   [SwitchA] portal web-server newpt
   [SwitchA-portal-websvr-newpt] url http://192.168.0.111:8080/portal
   [SwitchA-portal-websvr-newpt] quit
   ```

   # Enable cross-subnet portal authentication on VLAN-interface 4.

   ```
   [SwitchA] interface vlan-interface 4
   [SwitchA–Vlan-interface4] portal enable method layer3
   ```

   # Specify portal Web server **newpt** on VLAN-interface 4.

   ```
   [SwitchA–Vlan-interface4] portal apply web-server newpt
   ```

   # Configure the BAS-IP as 20.20.20.1 for portal packets sent from VLAN-interface 4 to the portal authentication server.

   ```
   [SwitchA–Vlan-interface4] portal bas-ip 20.20.20.1
   [SwitchA–Vlan-interface4] quit
   ```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[SwitchA] display portal interface vlan-interface 4
 Portal information of Vlan-interface4
     NAS-ID profile: Not configured
     M-LAG group ID: N/A
     M-LAG role    : N/A
     Authorization : Strict checking
     ACL           : Disabled
     User profile  : Disabled
     Max users     : Not configured
 IPv4:
     Portal status: Enabled
     Portal authentication method: Layer3
     Portal web server: newpt(active)
     Secondary portal Web server: Not configured
```

```
     Portal mac-trigger-server: Not configured
     Authentication domain: Not configured
     Pre-auth domain: Not configured
     User-dhcp-only: Disabled
     Pre-auth IP pool: Not configured
     Max users: Not configured
     Bas-ip: 20.20.20.1
     User detection:  Not configured
     Action for server detection:
         Server type    Server name                      Action
         --             --                               --
     Layer3 source network:
         IP address              Mask

     Destination authenticate subnet:
         IP address              Mask
IPv6:
     Portal status: Disabled
     Portal authentication method: Disabled    authentication shared mode: Disabled
     Portal web server: Not configured(active)
     Secondary portal Web server: Not configured
     Portal mac-trigger-server: Not configured
     Authentication domain: Not configured
     Pre-auth domain: Not configured
     User-dhcp-only: Disabled
     Pre-auth IP pool: Not configured
     Max users: Not configured
     Bas-ipv6: Not configured
     User detection: Not configured
     Action for server detection:
         Server type    Server name                      Action
         --             --                               --
     Layer3 source network:
         IP address                                      Prefix length

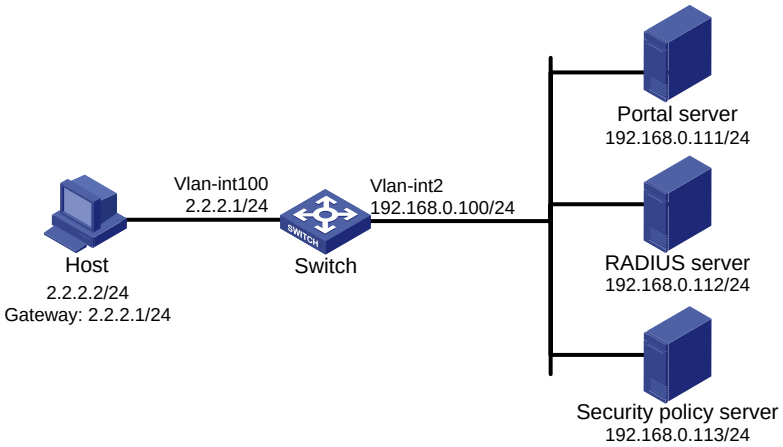
     Destination authenticate subnet:
         IP address                                      Prefix length
```

A user can perform portal authentication by using the iNode client or through a Web browser. Before passing the authentication, the user can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page. After passing the authentication, the user can access other network resources.

After the user passes authentication, use the following command to display information about the portal user.

```
[SwitchA] display portal user interface vlan-interface 4
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
```

```
MAC               IP              VLAN   Interface
0000-0000-0000    8.8.8.2         4      Vlan-interface4
Authorization information:
  DHCP IP pool: N/A
  User profile: N/A
  Session group profile: N/A
  ACL number: N/A
  Inbound CAR: N/A
  Outbound CAR: N/A
  Microsegment ID: N/A
```



Example: Configuring extended direct portal authentication

Network configuration

As shown in Figure 10, the host is directly connected to the switch (the access device). The host is assigned a public IP address either manually or through DHCP. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure extended direct portal authentication. If the host fails security check after passing identity authentication, it can access only subnet 192.168.0.0/24. After passing security check, the host can access other network resources.

Figure 10 Network diagram

Prerequisites

- Configure IP addresses for the host, switch, and servers as shown in Figure 10 and make sure they can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1** and enter its view.

   ```
   <Switch> system-view
   [Switch] radius scheme rs1
   ```

   # Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

   ```
   [Switch-radius-rs1] primary authentication 192.168.0.112
   ```

```
[Switch-radius-rs1] primary accounting 192.168.0.112
[Switch-radius-rs1] key accounting simple radius
[Switch-radius-rs1] key authentication simple radius
[Switch-radius-rs1] user-name-format without-domain
```

Enable RADIUS session control.

```
[Switch] radius session-control enable
```

Specify a session-control client with IP address 192.168.0.112 and shared key 12345 in plaintext form.

```
[Switch] radius session-control client ip 192.168.0.112 key simple 12345
```

2. Configure an authentication domain:

Create an ISP domain named dm1 and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain dm1 as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure ACL 3000 as the isolation ACL and ACL 3001 as the security ACL.

```
[Switch] acl advanced 3000
[Switch-acl-ipv4-adv-3000] rule permit ip destination 192.168.0.0 0.0.0.255
[Switch-acl-ipv4-adv-3000] rule deny ip
[Switch-acl-ipv4-adv-3000] quit
[Switch] acl advanced 3001
[Switch-acl-ipv4-adv-3001] rule permit ip
[Switch-acl-ipv4-adv-3001] quit
```

NOTE:

Make sure you specify ACL 3000 as the isolation ACL and ACL 3001 as the security ACL on the security policy server.

4. Configure portal authentication:

Configure a portal authentication server.

```
[Switch] portal server newpt
[Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
[Switch-portal-server-newpt] port 50100
[Switch-portal-server-newpt] quit
```

Configure a portal Web server.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Switch-portal-websvr-newpt] quit
```

Enable direct portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal enable method direct
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
```

Configure the BAS-IP as 2.2.2.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

```
[Switch–Vlan-interface100] portal bas-ip 2.2.2.1
[Switch–Vlan-interface100] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[Switch] display portal interface vlan-interface 100
 Portal information of Vlan-interface100
     NAS-ID profile: Not configured
     M-LAG group ID: N/A
     M-LAG role    : N/A

Action for server detection:
    Server type    Server name                          Action
    --             --                                   --
Layer3 source network:
    IP address                                          Prefix length

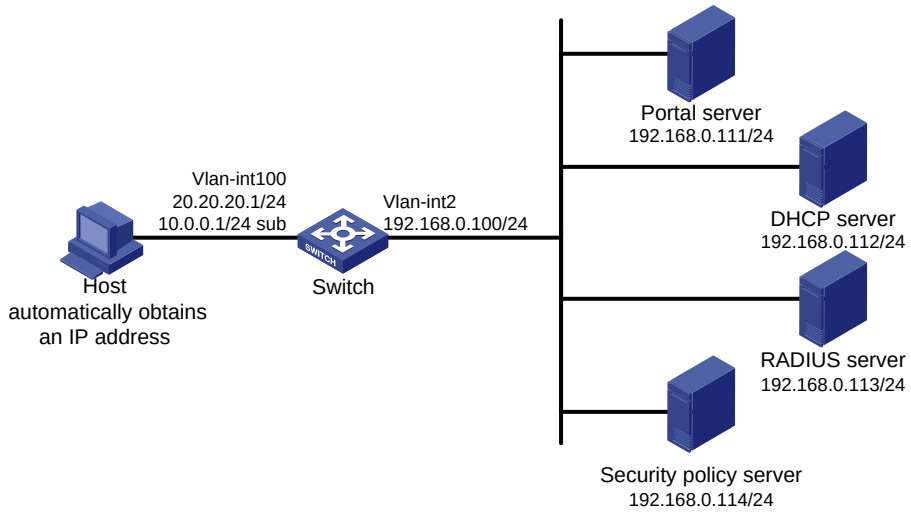
Destination authenticate subnet:
    IP address                                          Prefix length
```

Before passing portal authentication, a user that uses the iNode client can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page.

- The user can access the resources permitted by ACL 3000 after passing only identity authentication.
- The user can access network resources permitted by ACL 3001 after passing both identity authentication and security check.

After the user passes identity authentication and security check, use the following command to display information about the portal user.

```
[Switch] display portal user interface vlan-interface 100
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  0015-e9a6-7cfe    2.2.2.2           100    Vlan-interface100
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL: 3001
    Inbound CAR: N/A
    Outbound CAR: N/A
    Microsegment ID: N/A
```



Example: Configuring extended re-DHCP portal authentication

Network configuration

As shown in Figure 11, the host is directly connected to the switch (the access device). The host obtains an IP address through the DHCP server. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure extended re-DHCP portal authentication. Before passing portal authentication, the host is assigned a private IP address. After passing portal identity authentication, the host obtains a public IP address and accepts security check. If the host fails the security check, it can access only subnet 192.168.0.0/24. After passing the security check, the host can access other network resources.

Figure 11 Network diagram

Restrictions and guidelines

- For re-DHCP portal authentication, configure a public address pool (20.20.20.0/24) and a private address pool (10.0.0.0/24) on the DHCP server. (Details not shown.)
- For re-DHCP portal authentication:
  - The switch must be configured as a DHCP relay agent.
  - The portal-enabled interface must be configured with a primary IP address (a public IP address) and a secondary IP address (a private IP address).

  For information about DHCP relay agent configuration, see *Layer 3—IP Services Configuration Guide*.
- Make sure the IP address of the portal device added on the portal server is the public IP address (20.20.20.1) of the switch's interface connecting the host. The private IP address range for the IP address group associated with the portal device is the private subnet 10.0.0.0/24 where the host resides. The public IP address range for the IP address group is the public subnet 20.20.20.0/24.

Prerequisites

- Configure IP addresses for the switch and servers as shown in Figure 11 and make sure the host, switch, and servers can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<Switch> system-view
[Switch] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 192.168.0.113
[Switch-radius-rs1] primary accounting 192.168.0.113
[Switch-radius-rs1] key accounting simple radius
[Switch-radius-rs1] key authentication simple radius
[Switch-radius-rs1] user-name-format without-domain
```

Enable RADIUS session control.

```
[Switch] radius session-control enable
```

Specify a session-control client with IP address 192.168.0.113 and shared key 12345 in plaintext form.

```
[Switch] radius session-control client ip 192.168.0.113 key simple 12345
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure ACL 3000 as the isolation ACL and ACL 3001 as the security ACL.

```
[Switch] acl advanced 3000
[Switch-acl-ipv4-adv-3000] rule permit ip destination 192.168.0.0 0.0.0.255
[Switch-acl-ipv4-adv-3000] rule deny ip
[Switch-acl-ipv4-adv-3000] quit
[Switch] acl advanced 3001
[Switch-acl-ipv4-adv-3001] rule permit ip
[Switch-acl-ipv4-adv-3001] quit
```

NOTE:

Make sure you specify ACL 3000 as the isolation ACL and ACL 3001 as the security ACL on the security policy server.

4. Configure DHCP relay and authorized ARP:

Configure DHCP relay.

```
[Switch] dhcp enable
[Switch] dhcp relay client-information record
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] ip address 20.20.20.1 255.255.255.0
[Switch–Vlan-interface100] ip address 10.0.0.1 255.255.255.0 sub
[Switch-Vlan-interface100] dhcp select relay
[Switch-Vlan-interface100] dhcp relay server-address 192.168.0.112
```

Enable authorized ARP.

```
[Switch-Vlan-interface100] arp authorized enable
[Switch-Vlan-interface100] quit
```

5. Configure portal authentication:

Configure a portal authentication server.

```
[Switch] portal server newpt
[Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
[Switch-portal-server-newpt] port 50100
[Switch-portal-server-newpt] quit
```

Configure a portal Web server.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Switch-portal-websvr-newpt] quit
```

Enable re-DHCP portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal enable method redhcp
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
```

Configure the BAS-IP as 20.20.20.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

```
[Switch–Vlan-interface100] portal bas-ip 20.20.20.1
[Switch–Vlan-interface100] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[Switch] display portal interface vlan-interface 100
 Portal information of Vlan-interface100
     NAS-ID profile: Not configured
     M-LAG group ID: N/A
     M-LAG role    : N/A

    Layer3 source network:
        IP address                                     Prefix length

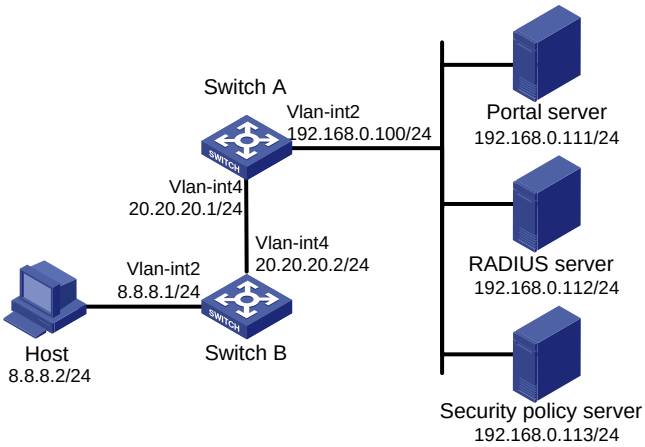
    Destination authenticate subnet:
        IP address                                     Prefix length
```

Before passing portal authentication, a user that uses the iNode client can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page.

- The user can access the resources permitted by ACL 3000 after passing only identity authentication.
- The user can access network resources permitted by ACL 3001 after passing both identity authentication and security check.

After the user passes identity authentication and security check, use the following command to display information about the portal user.

```
[Switch] display portal user interface vlan-interface 100
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  0015-e9a6-7cfe    20.20.20.2        100    Vlan-interface100
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: 3001 (active)
    Inbound CAR: N/A
    Outbound CAR: N/A
    Microsegment ID: N/A
```



Example: Configuring extended cross-subnet portal authentication

Network configuration

As shown in Figure 12, Switch A supports portal authentication. The host accesses Switch A through Switch B. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure Switch A for extended cross-subnet portal authentication. Before passing portal authentication, the host can access only the portal server. After passing portal identity authentication, the host accepts security check. If the host fails the security check it can access only the subnet 192.168.0.0/24. After passing the security check, the host can access other network resources.

Figure 12 Network diagram

Restrictions and guidelines

Make sure the IP address of the portal device added on the portal server is the IP address (20.20.20.1) of the switch's interface connecting the host. The IP address group associated with the portal device is the subnet of the host (8.8.8.0/24).

Prerequisites

- Configure IP addresses for the switch and servers as shown in Figure 12 and make sure the host, switch, and servers can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<SwitchA> system-view
[SwitchA] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[SwitchA-radius-rs1] primary authentication 192.168.0.112
[SwitchA-radius-rs1] primary accounting 192.168.0.112
[SwitchA-radius-rs1] key accounting simple radius
[SwitchA-radius-rs1] key authentication simple radius
[SwitchA-radius-rs1] user-name-format without-domain
```

Enable RADIUS session control.

```
[SwitchA] radius session-control enable
```

Specify a session-control client with IP address 192.168.0.112 and shared key 12345 in plaintext form.

```
[SwitchA] radius session-control client ip 192.168.0.112 key simple 12345
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[SwitchA] domain dm1
```

Configure AAA methods for the ISP domain.

```
[SwitchA-isp-dm1] authentication portal radius-scheme rs1
[SwitchA-isp-dm1] authorization portal radius-scheme rs1
[SwitchA-isp-dm1] accounting portal radius-scheme rs1
[SwitchA-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[SwitchA] domain default enable dm1
```

3. Configure ACL 3000 as the isolation ACL and ACL 3001 as the security ACL.

```
[SwitchA] acl advanced 3000
[SwitchA-acl-ipv4-adv-3000] rule permit ip destination 192.168.0.0 0.0.0.255
[SwitchA-acl-ipv4-adv-3000] rule deny ip
[SwitchA-acl-ipv4-adv-3000] quit
[SwitchA] acl advanced 3001
[SwitchA-acl-ipv4-adv-3001] rule permit ip
[SwitchA-acl-ipv4-adv-3001] quit
```

NOTE:

Make sure you specify ACL 3000 as the isolation ACL and ACL 3001 as the security ACL on the security policy server.

4. Configure portal authentication:

Configure a portal authentication server.

```
[SwitchA] portal server newpt
[SwitchA-portal-server-newpt] ip 192.168.0.111 key simple portal
[SwitchA-portal-server-newpt] port 50100
[SwitchA-portal-server-newpt] quit
```

Configure a portal Web server.

```
[SwitchA] portal web-server newpt
[SwitchA-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[SwitchA-portal-websvr-newpt] quit
```

Enable cross-subnet portal authentication on VLAN-interface 4.

```
[SwitchA] interface vlan-interface 4
[SwitchA–Vlan-interface4] portal enable method layer3
```

Specify portal Web server **newpt** on VLAN-interface 4.

```
[SwitchA–Vlan-interface4] portal apply web-server newpt
```

Configure the BAS-IP as 20.20.20.1 for portal packets sent from VLAN-interface 4 to the portal authentication server.

```
[SwitchA–Vlan-interface4] portal bas-ip 20.20.20.1
[SwitchA–Vlan-interface4] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[SwitchA] display portal interface vlan-interface 4
 Portal information of Vlan-interface4
     NAS-ID profile: Not configured
     M-LAG group ID: N/A
     M-LAG role    : N/A
     Authorization : Strict checking
     ACL           : Disabled
     User profile  : Disabled
     Max users     : Not configured

     Portal mac-trigger-server: Not configured
     Authentication domain: Not configured
     Pre-auth domain: Not configured
     User-dhcp-only: Disabled
     Pre-auth IP pool: Not configured
     Max users: Not configured
     Bas-ip: 20.20.20.1
     User detection:  Not configured
     Action for server detection:
         Server type    Server name                        Action
         --             --                                 --
     Layer3 source network:
         IP address              Mask

     Destination authenticate subnet:
         IP address              Mask
IPv6:
     Portal status: Disabled
     Portal authentication method: Disabled    authentication shared mode: Disabled
     Portal web server: Not configured(active)
     Secondary portal Web server: Not configured
     Portal mac-trigger-server: Not configured
     Authentication domain: Not configured
     Pre-auth domain: Not configured
     User-dhcp-only: Disabled
     Pre-auth IP pool: Not configured
     Max users: Not configured
     Bas-ip: Not configured
     User detection: Not configured
     Action for server detection:
         Server type    Server name                        Action
         --             --                                 --
```

```
Layer3 source network:
    IP address                                      Prefix length

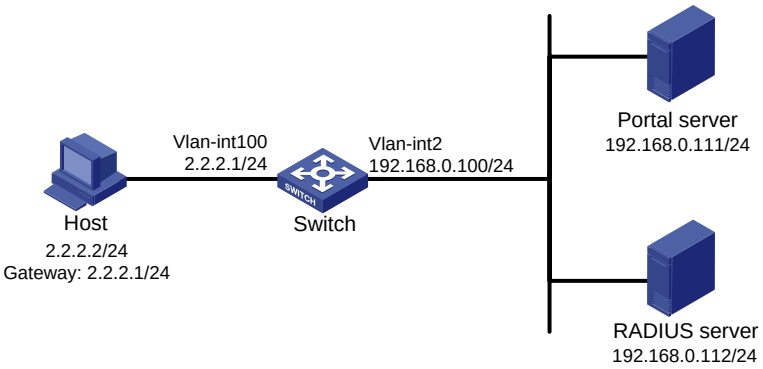
Destination authenticate subnet:
    IP address                                      Prefix length
```

Before passing portal authentication, a user that uses the iNode client can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page.

- The user can access the resources permitted by ACL 3000 after passing only identity authentication.
- The user can access network resources permitted by ACL 3001 after passing both identity authentication and security check.

After the user passes identity authentication and security check, use the following command to display information about the portal user.

```
[SwitchA] display portal user interface vlan-interface 4
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  0015-e9a6-7cfe    8.8.8.2           4    Vlan-interface4
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: 3001 (active)
    Inbound CAR: N/A
    Outbound CAR: N/A
    Microsegment ID: N/A
```



Example: Configuring portal server detection and portal user synchronization

Network configuration

As shown in Figure 13, the host is directly connected to the switch (the access device). The host is assigned a public IP address either manually or through DHCP. An IMC server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

- Configure direct portal authentication on the switch, so the host can access only the portal server before passing the authentication and access other network resources after passing the authentication.
- Configure the switch to detect the reachability state of the portal authentication server, send log messages upon state changes, and disable portal authentication when the authentication server is unreachable.
- Configure the switch to synchronize portal user information with the portal server periodically.

Figure 13 Network diagram

Prerequisites

- Configure IP addresses for the switch and servers and make sure the host, switch, and servers can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.
- Configure the portal service on the IMC server, including setting portal server parameters, adding access devices, creating user IP address groups, and configuring device port groups to associate with IP address groups. This ensures coordinated implementation of portal authentication with the device.

Configuring the switch

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<Switch> system-view
[Switch] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 192.168.0.112
[Switch-radius-rs1] primary accounting 192.168.0.112
[Switch-radius-rs1] key authentication simple radius
[Switch-radius-rs1] key accounting simple radius
```

Exclude the ISP domain name from the username sent to the RADIUS server.

```
[Switch-radius-rs1] user-name-format without-domain
[Switch-radius-rs1] quit
```

Enable RADIUS session control.

```
[Switch] radius session-control enable
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure portal authentication:

   # Configure a portal authentication server.

   ```
   [Switch] portal server newpt
   [Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
   [Switch-portal-server-newpt] port 50100
   ```

   # Configure reachability detection of the portal authentication server: set the server detection interval to 40 seconds, and send log messages upon reachability status changes.

   ```
   [Switch-portal-server-newpt] server-detect timeout 40 log
   ```

   NOTE:

   The value of **timeout** must be greater than or equal to the portal server heartbeat interval.

   # Configure portal user synchronization with the portal authentication server, and set the synchronization detection interval to 600 seconds.

   ```
   [Switch-portal-server-newpt] user-sync timeout 600
   [Switch-portal-server-newpt] quit
   ```

   NOTE:

   The value of **timeout** must be greater than or equal to the portal user heartbeat interval.

   # Configure a portal Web server.

   ```
   [Switch] portal web-server newpt
   [Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
   [Switch-portal-websvr-newpt] quit
   ```

   # Enable direct portal authentication on VLAN-interface 100.

   ```
   [Switch] interface vlan-interface 100
   [Switch–Vlan-interface100] portal enable method direct
   ```

   # Enable portal fail-permit for the portal authentication server **newpt**.

   ```
   [Switch–Vlan-interface100] portal fail-permit server newpt
   ```

   # Specify portal Web server **newpt** on VLAN-interface 100.

   ```
   [Switch–Vlan-interface100] portal apply web-server newpt
   ```

   # Configure the BAS-IP as 2.2.2.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

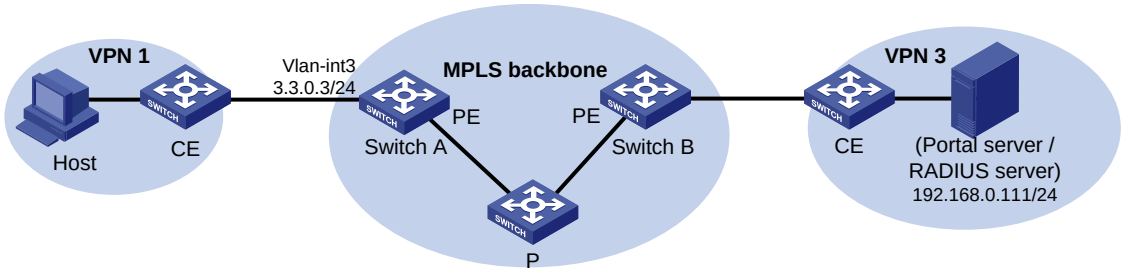
   ```
   [Switch–Vlan-interface100] portal bas-ip 2.2.2.1
   [Switch–Vlan-interface100] quit
   ```

Verifying the configuration

Use the following command to display information about the portal authentication server.

```
[Switch] display portal server newpt
Portal server: newpt
  Type                  : IMC
  IP                    : 192.168.0.111
  VPN instance          : Not configured
  Port                  : 50100
  Server Detection      : Timeout 40s  Action: log
  User synchronization  : Timeout 600s
  Status                : Up
```

The **Up** status of the portal authentication server indicates that the portal authentication server is reachable. If the access device detects that the portal authentication server is unreachable, the **Status** field in the command output displays **Down**. The access device generates a server unreachable log "Portal server newpt turns down from up." and disables portal authentication on the access interface, so the host can access the external network without authentication.



Example: Configuring cross-subnet portal authentication for MPLS L3VPNs

Network configuration

As shown in Figure 14, the PE device Switch A provides portal authentication for the host in VPN 1. A portal server in VPN 3 acts as the portal authentication server, portal Web server, and RADIUS server.

Configure cross-subnet portal authentication on Switch A, so the host can access network resources after passing identity authentication.

Figure 14 Network diagram

Prerequisites

- Before enabling portal authentication, configure MPLS L3VPN and specify VPN targets for VPN 1 and VPN 3 so that VPN 1 and VPN 3 can communicate with each other. This example describes only the access authentication configuration on the user-side PE. For information about MPLS L3VPN configurations, see MPLS L3VPN configuration in *MCE Configuration Guide*.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1** and enter its view.

   ```
   <SwitchA> system-view
   [SwitchA] radius scheme rs1
   ```

   # For the RADIUS scheme, specify the VPN instance that is bound to the interface connected to the portal/RADIUS server. This example uses VPN instance **vpn3**. (For information about the VPN instance, see the MPLS L3VPN configuration on Switch A.)

   ```
   [SwitchA-radius-rs1] vpn-instance vpn3
   ```

   # Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

   ```
   [SwitchA-radius-rs1] primary authentication 192.168.0.111
   [SwitchA-radius-rs1] primary accounting 192.168.0.111
   [SwitchA-radius-rs1] key accounting simple radius
   [SwitchA-radius-rs1] key authentication simple radius
   ```

   # Exclude the ISP domain name from the username sent to the RADIUS server.

```
[SwitchA-radius-rs1] user-name-format without-domain
```

Specify the source IP address for RADIUS packets to be sent as 3.3.0.3. This address must be the same as that of the portal device specified on the portal authentication server to avoid authentication failures.

```
[SwitchA-radius-rs1] nas-ip 3.3.0.3
[SwitchA-radius-rs1] quit
```

Enable RADIUS session control.

```
[SwitchA] radius session-control enable
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[SwitchA] domain dm1
```

Configure AAA methods for the ISP domain.

```
[SwitchA-isp-dm1] authentication portal radius-scheme rs1
[SwitchA-isp-dm1] authorization portal radius-scheme rs1
[SwitchA-isp-dm1] accounting portal radius-scheme rs1
[SwitchA-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[SwitchA] domain default enable dm1
```

3. Configure portal authentication:

Configure a portal authentication server.

```
[SwitchA] portal server newpt
[SwitchA-portal-server-newpt] ip 192.168.0.111 vpn-instance vpn3 key simple portal
[SwitchA-portal-server-newpt] port 50100
[SwitchA-portal-server-newpt] quit
```

Configure a portal Web server.

```
[SwitchA] portal web-server newpt
[SwitchA-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[SwitchA-portal-websvr-newpt] vpn-instance vpn3
[SwitchA-portal-websvr-newpt] quit
```

Enable cross-subnet portal authentication on VLAN-interface 3.

```
[SwitchA] interface vlan-interface 3
[SwitchA–Vlan-interface3] portal enable method layer3
```

Specify portal Web server **newpt** on VLAN-interface 3.

```
[SwitchA–Vlan-interface3] portal apply web-server newpt
```

Configure the BAS-IP as 3.3.0.3 for portal packets sent from VLAN-interface 3 to the portal authentication server.

```
[SwitchA–Vlan-interface3] portal bas-ip 3.3.0.3
[SwitchA–Vlan-interface3] quit
```

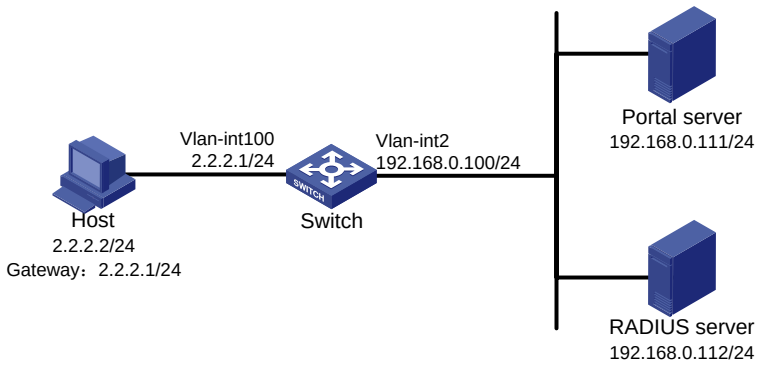
Verifying the configuration

Verify the portal configuration by executing the **`display portal interface`** command. (Details not shown.)

After the user passes authentication, execute the **`display portal user`** command to display the portal user information.

```
[SwitchA] display portal user all
Total portal users: 1
```

```
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: vpn3
  MAC               IP                VLAN   Interface
  000d-88f7-c268    3.3.0.1           3      Vlan-interface3
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
    Microsegment ID: N/A
```



Example: Configuring direct portal authentication with a preauthentication domain

Network configuration

As shown in Figure 15, the host is directly connected to the switch (the access device). The host is assigned a public IP address through DHCP. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure direct portal authentication, so the host can access only subnet 192.168.0.0/24 before passing the authentication and access other network resources after passing the authentication.

Figure 15 Network diagram

Prerequisites

- Configure IP addresses for the host, switch, and servers as shown in Figure 15 and make sure they can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a preauthentication IP address pool:

   # Configure DHCP address pool **pre** to assign IP addresses and other configuration parameters to clients on subnet 2.2.2.0/24.

   ```
   <Switch> system-view
   [Switch] dhcp server ip-pool pre
   ```

```
[Switch-dhcp-pool-pre] gateway-list 2.2.2.1
[Switch-dhcp-pool-pre] network 2.2.2.0 24
[Switch-dhcp-pool-pre] quit
```

Enable the DHCP server on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] dhcp select server
[Switch–Vlan-interface100] quit
```

2. Configure a portal preauthentication domain:

Create an ISP domain named **abc**.

```
[Switch] domain abc
```

Specify user attribute ACL 3010 in the ISP domain.

```
[Switch-isp-abc] authorization-attribute acl 3010
[Switch-isp-abc] quit
```

In ACL 3010, configure a rule to permit access to the subnet 192.168.0.0/24.

```
[Switch] acl advanced 3010
[Switch-acl-ipv4-adv-3010] rule 1 permit ip destination 192.168.0.0 0.0.0.255
[Switch-acl-ipv4-adv-3010] quit
```

Specify ISP domain **abc** as the portal authentication domain on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal pre-auth domain abc
[Switch–Vlan-interface100] quit
```

3. Configure portal authentication:

Configure a portal authentication server.

```
[Switch] portal server newpt
[Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
[Switch-portal-server-newpt] port 50100
[Switch-portal-server-newpt] quit
```

Configure a portal Web server.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Switch-portal-websvr-newpt] quit
```

Enable direct portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal enable method direct
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
```

Configure the BAS-IP as 2.2.2.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

```
[Switch–Vlan-interface100] portal bas-ip 2.2.2.1
[Switch–Vlan-interface100] quit
```

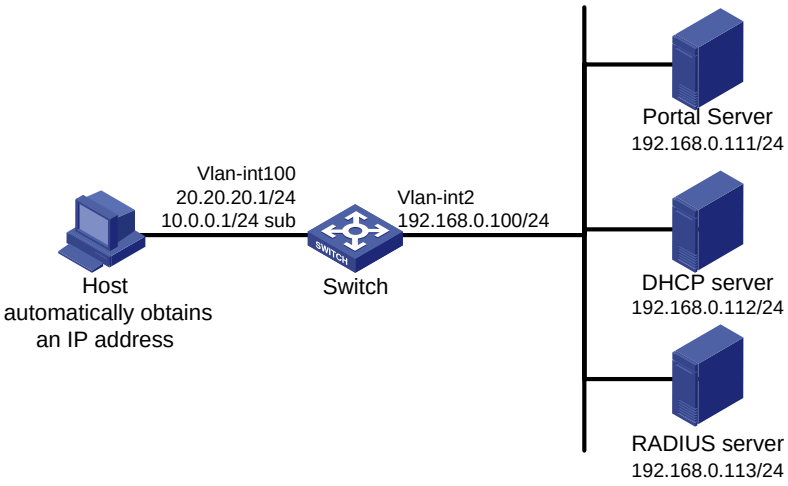
Verifying the configuration

Verify the portal configuration by executing the **`display portal interface`** command. (Details not shown.)

Display information about preauthentication portal users.

```
[Switch] display portal user pre-auth interface vlan-interface 100
MAC               IP                VLAN   Interface
0015-e9a6-7cfe    10.10.10.4        100     Vlan-interface100
```

```
State: Online
VPN instance: N/A
Authorization information:
  User profile: N/A
  Session group profile: N/A
  ACL number: 3010 (active)
  Inbound CAR: N/A
  Outbound CAR: N/A
  Microsegment ID: N/A
```



Example: Configuring re-DHCP portal authentication with a preauthentication domain

Network configuration

As shown in Figure 16, the host is directly connected to the switch (the access device). The host obtains an IP address through the DHCP server. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure re-DHCP portal authentication. Before passing the authentication, the host is assigned a private IP address and can access only the subnet 192.168.0.0/24. After passing the authentication, the host gets a public IP address and can access other network resources.

Figure 16 Network diagram

Restrictions and guidelines

- For re-DHCP portal authentication, configure a public address pool (20.20.20.0/24) and a private address pool (10.0.0.0/24) on the DHCP server. (Details not shown.)
- For re-DHCP portal authentication:
  - The switch must be configured as a DHCP relay agent.
  - The portal-enabled interface must be configured with a primary IP address (a public IP address) and a secondary IP address (a private IP address).

  For information about DHCP relay agent configuration, see *Layer 3—IP Services Configuration Guide*.
- Make sure the IP address of the portal device added on the portal server is the public IP address (20.20.20.1) of the switch's interface connecting the host. The private IP address range for the IP address group associated with the portal device is the private subnet 10.0.0.0/24

where the host resides. The public IP address range for the IP address group is the public subnet 20.20.20.0/24.

- If you have configured a preauthentication IP address pool on portal-enabled interfaces, configure a DHCP relay address pool with the same name on the device. For the DHCP relay address pool, specify the subnet address where the unauthenticated users reside (with the **`export-router`** keyword specified) and the DHCP server address.

Prerequisites

- Configure IP addresses for the switch and servers as shown in Figure 16 and make sure the host, switch, and servers can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a portal preauthentication domain:

Create an ISP domain named **abc**.

```
<Switch> system-view
[Switch] domain abc
```

Specify user attribute ACL 3010 in the ISP domain.

```
[Switch-isp-abc] authorization-attribute acl 3010
[Switch-isp-abc] quit
```

In ACL 3010, configure a rule to permit access to the subnet 192.168.0.0/24.

```
[Switch] acl advanced 3010
[Switch-acl-ipv4-adv-3010] rule 1 permit ip destination 192.168.0.0 0.0.0.255
[Switch-acl-ipv4-adv-3010] quit
```

Specify ISP domain **abc** as the portal authentication domain on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal pre-auth domain abc
[Switch–Vlan-interface100] quit
```

2. Configure DHCP relay and authorized ARP.

Configure DHCP relay.

```
[Switch] dhcp enable
[Switch] dhcp relay client-information record
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] ip address 20.20.20.1 255.255.255.0
[Switch–Vlan-interface100] ip address 10.0.0.1 255.255.255.0 sub
[Switch-Vlan-interface100] dhcp select relay
[Switch-Vlan-interface100] dhcp relay server-address 192.168.0.112
```

Enable authorized ARP.

```
[Switch-Vlan-interface100] arp authorized enable
[Switch-Vlan-interface100] quit
```

3. Configure portal authentication:

Configure a portal authentication server.

```
[Switch] portal server newpt
[Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
[Switch-portal-server-newpt] port 50100
[Switch-portal-server-newpt] quit
```

Configure a portal Web server.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
```

```
[Switch-portal-websvr-newpt] quit
```

Enable re-DHCP portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch-Vlan-interface100] portal enable method redhcp
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
```

Configure the BAS-IP as 20.20.20.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

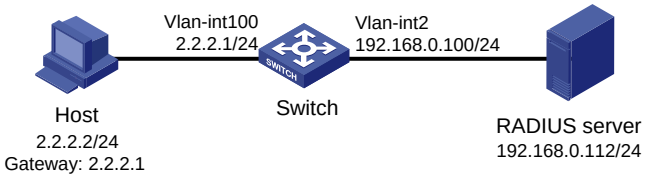
```
[Switch–Vlan-interface100] portal bas-ip 20.20.20.1
[Switch–Vlan-interface100] quit
```

Verifying the configuration

Verify the portal configuration by executing the **`display portal interface`** command. (Details not shown.)

Display information about preauthentication portal users.

```
[Switch] display portal user pre-auth interface vlan-interface 100
MAC                IP                 VLAN   Interface
0015-e9a6-7cfe     10.10.10.4         100     Vlan-interface100
  State: Online
  VPN instance: N/A
  Authorization information:
    User profile: N/A
    Session group profile: N/A
    ACL number: 3010 (active)
    Inbound CAR: N/A
    Outbound CAR: N/A
    Microsegment ID: N/A
```



Example: Configuring direct portal authentication using a local portal Web service

Network configuration

As shown in Figure 17, the host is directly connected to the switch (the access device). The host is assigned a public IP address either manually or through DHCP. The switch acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure direct portal authentication on the switch. Before a user passes portal authentication, the user can access only the portal Web server. After passing portal authentication, the user can access other network resources.

Figure 17 Network diagram

Prerequisites

- Configure IP addresses for the host, switch, and server as shown in Figure 17 and make sure they can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<Switch> system-view
[Switch] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 192.168.0.112
[Switch-radius-rs1] primary accounting 192.168.0.112
[Switch-radius-rs1] key authentication simple radius
[Switch-radius-rs1] key accounting simple radius
```

Exclude the ISP domain name from the username sent to the RADIUS server.

```
[Switch-radius-rs1] user-name-format without-domain
[Switch-radius-rs1] quit
```

Enable RADIUS session control.

```
[Switch] radius session-control enable
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure portal authentication:

Configure a portal Web server named **newpt** and specify **http://2.2.2.1:2331/portal** as the URL of the portal Web server. The IP address in the URL must be the IP address of a Layer 3 interface reachable to portal clients or a loopback interface (except 127.0.0.1) on the device.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://2.2.2.1:2331/portal
[Switch-portal-websvr-newpt] quit
```

Enable direct portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal enable method direct
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
[Switch–Vlan-interface100] quit
```

Create an HTTP-based local portal Web service and enter its view.

```
[Switch] portal local-web-server http
```

Specify file **defaultfile.zip** as the default authentication page file for the local portal Web service. (Make sure the file exists under the root directory of the switch.)

```
[Switch–portal-local-websvr-http] default-logon-page defaultfile.zip
```

Set the HTTP listening port number to 2331 for the local portal Web service.

```
[Switch–portal-local-webserver-http] tcp-port 2331
[Switch–portal-local-websvr-http] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[Switch] display portal interface vlan-interface 100
 Portal information of Vlan-interface 100
     M-LAG group ID: N/A
     M-LAG role    : N/A
     Authorization                   Strict checking
     ACL                             Disabled
     User profile                    Disabled
 IPv4:
     Portal status: Enabled
     Portal authentication method: Direct    authentication shared mode: Disabled
     Portal web server: newpt(active)
     Secondary portal Web server: Not configured
     Portal mac-trigger-server: Not configured
     Authentication domain: Not configured
     Pre-auth domain: Not configured
     User-dhcp-only: Disabled
     Pre-auth IP pool: Not configured
     Max users: Not configured
     Bas-ip: Not configured
     User detection:  Not configured
     Action for server detection:
         Server type    Server name                          Action
         --             --                                   --
     Layer3 source network:
         IP address              Mask

     Destination authenticate subnet:
         IP address              Mask
IPv6:
     Portal status: Disabled
     Portal authentication method: Disabled    authentication shared mode: Disabled
     Portal web server: Not configured
     Secondary portal Web server: Not configured
     Portal mac-trigger-server: Not configured
     Authentication domain: Not configured
     Pre-auth domain: Not configured
     User-dhcp-only: Disabled
     Pre-auth IP pool: Not configured
     Max users: Not configured
     Bas-ipv6: Not configured
```

```
    User detection: Not configured
    Action for server detection:
        Server type    Server name                          Action
        --             --                                   --
    Layer3 source network:
        IP address                                          Prefix length

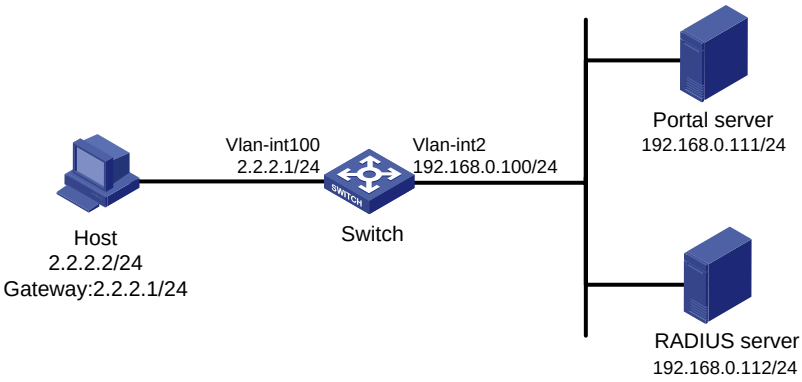
    Destination authenticate subnet:
        IP address                                          Prefix length
```

A user can perform portal authentication through a Web page. Before passing the authentication, the user can access only the authentication page **http://2.2.2.1:2331/portal** and all Web requests will be redirected to the authentication page. After passing the authentication, the user can access other network resources.

After the user passes authentication, use the following command to display information about the portal user.

```
[Switch] display portal user interface vlan-interface 100
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  0015-e9a6-7cfe    2.2.2.2           100     Vlan-interface100
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
    Microsegment ID: N/A
```

Example: Configuring MAC-based quick portal authentication



Network configuration

As shown in Figure 18, the host accesses the network through the switch. The host is assigned a public IP address either manually or through DHCP.

An IMC server acts as a portal server (portal authentication server and portal Web server) and a MAC binding server. A RADIUS server acts as the authentication and accounting server.

Configure direct portal authentication, so the host can access only the portal Web server before passing the authentication and can access other network resources after passing the authentication.

Figure 18 Network diagram

Prerequisites

- Configure IP addresses for the host, switch, and servers and make sure they can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.
- Configure the portal service on the IMC server, including setting portal server parameters, adding access devices, creating user IP address groups, and configuring device port groups to associate with IP address groups. This ensures coordinated implementation of portal authentication with the device.
- Configure the MAC binding server on the IMC server, including adding access policies, configuring access services and access users, setting system parameters (such as MAC-based quick portal authentication and terminal aging policy), and manually activate these parameters to apply them to the system. This helps achieve MAC address binding and MAC-based quick portal authentication for terminals.

Configuring the switch

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1** and enter its view.

   ```
   <Switch> system-view
   [Switch] radius scheme rs1
   ```

   # Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

   ```
   [Switch-radius-rs1] primary authentication 192.168.0.112
   [Switch-radius-rs1] primary accounting 192.168.0.112
   [Switch-radius-rs1] key authentication simple radius
   [Switch-radius-rs1] key accounting simple radius
   ```

   # Exclude the ISP domain name from the username sent to the RADIUS server.

   ```
   [Switch-radius-rs1] user-name-format without-domain
   [Switch-radius-rs1] quit
   ```

   # Enable RADIUS session control.

   ```
   [Switch] radius session-control enable
   ```

2. Configure an authentication domain:

   # Create an ISP domain named **dm1** and enter its view.

   ```
   [Switch] domain dm1
   ```

   # Configure AAA methods for the ISP domain.

   ```
   [Switch-isp-dm1] authentication portal radius-scheme rs1
   [Switch-isp-dm1] authorization portal radius-scheme rs1
   ```

```
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure portal authentication:

Configure a portal authentication server.

```
[Switch] portal server newpt
[Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
[Switch-portal-server-newpt] port 50100
[Switch-portal-server-newpt] quit
```

Configure a portal Web server.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Switch-portal-websvr-newpt] quit
```

Enable direct authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch-Vlan-interface100] portal enable method direct
```

Specify the portal Web server **newpt** on VLAN-interface 100.

```
[Switch-Vlan-interface100] portal apply web-server newpt
```

Configure the BAS-IP as 2.2.2.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

```
[Switch-Vlan-interface100] portal bas-ip 2.2.2.1
[Switch-Vlan-interface100] quit
```

4. Configure MAC-based quick portal authentication:

Create the MAC binding server **mts**.

```
[Switch] portal mac-trigger-server mts
```

Set the free-traffic threshold for portal users to 1024000 bytes.

```
[Switch-portal-mac-trigger-server-mts] free-traffic threshold 1024000
```

Specify the IP address of the MAC binding server as 192.168.0.111.

```
[Switch-portal-mac-trigger-server-mts] ip 192.168.0.111
[Switch-portal-mac-trigger-server-mts] quit
```

Specify the MAC binding server **mts** on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch-Vlan-interface100] portal apply mac-trigger-server mts
[Switch-Vlan-interface100] quit
```

Verifying the configuration

Display information about the MAC binding server.

```
[Switch] display portal mac-trigger-server name mts
Portal mac trigger server name: mts
  Version                    : 1.0
  Server type                : IMC
  IP                         : 192.168.0.111
  Port                       : 50100
  VPN instance               : Not configured
  Aging time                 : 300 seconds
```

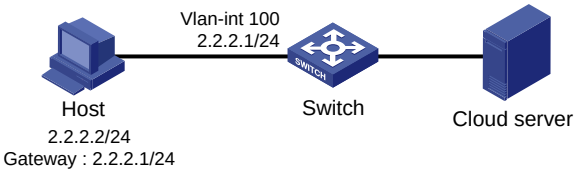
```
  Free-traffic threshold     : 1024000 bytes
  NAS-Port-Type              : Not configured
  Binding retry times        : 3
  Binding retry interval     : 1 seconds
  Authentication timeout     : 3 minutes
```

A user can perform portal authentication by using the iNode client or through a Web browser. Before passing the authentication, the user can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page. After passing the authentication, the user can access other network resources.

For the first portal authentication, the user is required to enter the username and password. When the user goes offline and then accesses the network again, the user does not need to enter the authentication username and password.

Display portal user information.

```
[Switch] display portal user interface vlan-interface 100
Total portal users: 1
Username: Client1
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  0015-e9a6-7cfe    2.2.2.2           100    Vlan-interface100
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
    Microsegment ID: N/A
```



Example: Configuring cloud MAC-trigger authentication

Network configuration

As shown in Figure 19, the host accesses the network through the switch. The host is assigned a public IP address either manually or through DHCP. A cloud server acts as a portal server (portal authentication server and portal Web server) and a MAC binding server.

Configure MAC-trigger authenticaiton (MAC-based quick portal authentication) that uses the cloud server, so the user can access only the portal Web server before passing the authentication and can access other network resources after passing the authentication. The user can pass portal authentication without entering a username or password when the user tries to come online again.

Figure 19 Network diagram

Configuring the cloud server

On the Oasis platform, enable **Auth free for reconnect** on the authentication template for the AC. (Details not shown.)

Configuring the switch

1. Configure IP addresses for the host, switch, and server and make sure they can reach each other. (Details not shown.)
2. Configure basic network functions:

   # Create VLAN 100. The host will use this VLAN to access the network.

   ```
   <Switch> system-view
   [Switch] vlan 100
   [Switch-vlan100] quit
   ```

   # Assign an IP address to the VLAN interface. (Details not shown.)

   # Enable DNS proxy.

   ```
   [Switch] dns proxy enable
   ```

3. Configure an authentication domain:

   # Create an ISP domain named **cloud** and enter its view.

   ```
   [Switch] domain cloud
   ```

   # Configure AAA methods for portal users in the ISP domain as none.

   ```
   [Switch-isp-cloud] authentication portal none
   [Switch-isp-cloud] authorization portal none
   [Switch-isp-cloud] accounting portal none
   [Switch-isp-cloud] quit
   ```

4. Configure cloud MAC-trigger authentication:

   # Configure a portal Web server named **wbs**.

   ```
   [Switch] portal web-server wbs
   [Switch-portal-websvr-wbs] url http://oasisauth.h3c.com
   [Switch-portal-websvr-wbs] server-type oauth
   [Switch-portal-websvr-wbs] url-parameter nas_id value
   cm-0-554212-210235A2G1B205000009
   [Switch-portal-websvr-wbs] url-parameter template_id value 4291
   ```

   # Create an HTTP-based local portal Web service and enter its view.

   ```
   [Switch] portal local-web-server http
   ```

   # Enable cloud MAC-trigger authentication.

   ```
   [Switch] portal mac-trigger-server abc
   [Switch-portal-extend-auth-server-abc] cloud-binding enable
   ```

   # Specify **https://oasisauth.h3c.com** as the URL of the cloud portal authentication server.

   ```
   [Switch-portal-extend-auth-server-abc] cloud-server url http://oasisauth.h3c.com
   [Switch-portal-extend-auth-server-abc] quit
   ```

   # Enable direct portal authentication on interface VLAN-interface 100.

   ```
   [Switch] interface vlan-interface 100
   [Switch-Vlan-interface100] portal enable method direct
   ```

   # Specify the authentication domain, portal Web server, and MAC binding server on interface VLAN-interface 100.

   ```
   [Switch-Vlan-interface100] portal domain cloud
   [Switch-Vlan-interface100] portal apply web-server cloud
   [Switch-Vlan-interface100] portal apply mac-trigger-server abc
   ```

Verifying the configuration

Display packet statistics for the cloud portal authentication server.

```
[Switch] display portal packet statistics extend-auth-server cloud
Extend-auth server : cloud
  Pkt-Type           Success      Error      Timeout      Conn-failure
  REQ_ACCESSTOKEN    1            0          0            0
  REQ_USERINFO       1            0          0            0
  RESP_ACCESSTOKEN   1            0          0            0
  RESP_USERINFO      1            0          0            0
  POST_ONLINEDATA    10           0          0            0
  RESP_ONLINEDATA    10           0          0            0
  POST_OFFLINEUSER   1            0          0            0
  REPORT_ONLINEUSER  2            0          0            0
  REQ_CLOUDBIND      2            0          0            0
  ESP_CLOUDBIND      2            0          0            0
  REQ_BINDUSERINFO   1            0          0            0
  RESP_BINDUSERINFO  1            0          0            0
  AUTHENTICATION     2            0          0            0
```

Before passing portal authentication, a user can access only the portal authentication page **http://oasisauth.h3c.com**. All Web requests from the user will be redirected to the portal authentication page. After passing portal authentication, the user can access other network resources.

The user needs to enter the username and password for the first authentication. If the user goes offline and then tries to come online, the user can directly access the network resources without entering the username and password.

Display information about portal users.

```
[Switch] display portal user interface vlan-interface 100
Total portal users: 1
Username: Client1
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC                IP                VLAN   Interface
  0015-e9a6-7cfe     2.2.2.2           --     vlan-interface 100
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
    Microsegment ID: N/A
```

Example: Configuring portal authentication to support M-LAG

Network configuration

As shown in Figure 20, the hosts access the network through Device C (Layer 2 device). Each host is assigned a public IP address either manually or through DHCP.

An IMC server acts as a portal server (portal authentication server and portal Web server). A RADIUS server acts as the authentication and accounting server.

Configure the devices as follows:

- Configure direct portal authentication, so the hosts can access only the portal server before passing the authentication and access other network resources after passing the authentication.
- Configure Device A and Device B to form an M-LAG system to load share traffic. When a device fails, the other device can take over to ensure service continuity.
- Set the authentication load sharing mode to distributed if a large number of portal users exist.

Figure 20 Network diagram

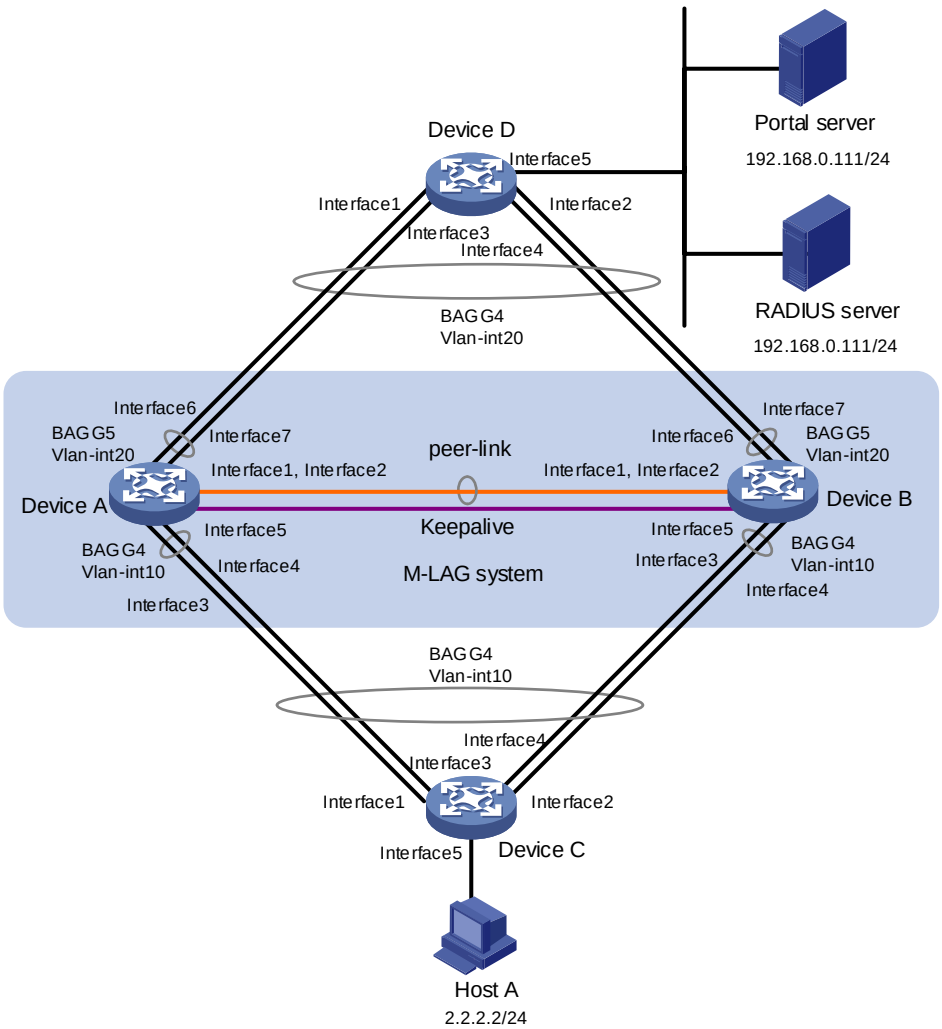


Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4
Interface5	GigabitEthernet1/0/5
Interface6	GigabitEthernet1/0/6

Interface7	GigabitEthernet1/0/7

Table 3 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Device A	Vlan-int10	2.2.2.1/24	Device B	Vlan-int10	2.2.2.1/24
Device A	Vlan-int20	3.3.3.1/24	Device B	Vlan-int20	3.3.3.1/24
Device A	GE1/0/3	1.1.1.1/24	Device B	GE1/0/3	1.1.1.2/24
Device C	Vlan-int10	2.2.2.3/24	Device D	Vlan-int10	3.3.3.3/24

Prerequisites

1. Configure IP addresses for the host, switch, and servers as shown in Figure 20 and make sure they can reach each other.
2. Configure the RADIUS server correctly to provide authentication and accounting functions.
3. Configure the portal service on the IMC server, including setting portal server parameters, adding access devices, creating user IP address groups, and configuring device port groups to associate with IP address groups. This ensures coordinated implementation of portal authentication with the device.

Configuring the M-LAG system

1. Configure Device A.

   # Configure M-LAG system settings.

   ```
   <DeviceA> system-view
   [DeviceA] m-lag system-mac 1-1-1
   [DeviceA] m-lag system-number 1
   [DeviceA] m-lag system-priority 123
   ```

   # Configure the destination and source IP addresses of keepalive packets.

   ```
   [DeviceA] m-lag keepalive ip destination 1.1.1.1 source 1.1.1.2
   ```

   # Configure port GigabitEthernet 1/0/3 to operate in Layer 3 mode and configure the source IP address of keepalive packets as the IP address of this port.

   ```
   [DeviceA] interface gigabitethernet 1/0/3
   [DeviceA-GigabitEthernet1/0/3] port link-mode route
   [DeviceA-GigabitEthernet1/0/3] ip address 1.1.1.2 24
   [DeviceA-GigabitEthernet1/0/3] quit
   ```

   # Exclude GigabitEthernet 1/0/5 (keepalive interface) from being shut down upon detection of multi-active collisions.

   ```
   [DeviceA] m-lag mad exclude interface gigabitethernet 1/0/5
   ```

   # Create Layer 2 aggregate interface Bridge-Aggregation 3 and set the aggregation mode to dynamic.

   ```
   [DeviceA] interface bridge-aggregation 3
   [DeviceA-Bridge-Aggregation3] link-aggregation mode dynamic
   [DeviceA-Bridge-Aggregation3] quit
   ```

   # Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 3.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] port link-aggregation group 3
   [DeviceA-GigabitEthernet1/0/1] quit
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] port link-aggregation group 3
   [DeviceA-GigabitEthernet1/0/2] quit
   ```

Configure Layer 2 aggregate interface Bridge-Aggregation 3 as a trunk port, add the interface to VLAN 10 and VLAN 20, and configure the interface as a peer-link interface.

```
[DeviceA] interface bridge-aggregation 3
[DeviceA-Bridge-Aggregation3] port link-type trunk
[DeviceA-Bridge-Aggregation3] port trunk permit vlan 10 20
[DeviceA-Bridge-Aggregation3] port m-lag peer-link 1
[DeviceA-Bridge-Aggregation3] quit
```

Allow packets from the peer-link interface to prevent packets from the peer end from being discarded due to portal deny rules.

```
[DeviceA] portal free-rule 1 source interface bridge-aggregation 3
```

Create Layer 2 aggregate interface Bridge-Aggregation 4 and set the aggregation mode to dynamic.

```
[DeviceA] interface bridge-aggregation 4
[DeviceA-Bridge-Aggregation4] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation4] quit
```

Assign GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to aggregation group 4.

```
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 4
[DeviceA-GigabitEthernet1/0/3] quit
[DeviceA] interface gigabitethernet 1/0/4
[DeviceA-GigabitEthernet1/0/4] port link-aggregation group 4
[DeviceA-GigabitEthernet1/0/4] quit
```

Add Layer 2 aggregate interface Bridge-Aggregation 4 to VLAN 10, and configure the interface as an M-LAG interface.

```
[DeviceA] interface bridge-aggregation 4
[DeviceA-Bridge-Aggregation4] port access vlan 10
[DeviceA-Bridge-Aggregation4] port m-lag group 4
[DeviceA-Bridge-Aggregation4] quit
```

Create Layer 2 aggregate interface Bridge-Aggregation 5 and set the aggregation mode to dynamic.

```
[DeviceA] interface bridge-aggregation 5
[DeviceA-Bridge-Aggregation5] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation5] quit
```

Assign GigabitEthernet 1/0/6 and GigabitEthernet 1/0/7 to aggregation group 5.

```
[DeviceA] interface gigabitethernet 1/0/6
[DeviceA-GigabitEthernet1/0/6] port link-aggregation group 5
[DeviceA-GigabitEthernet1/0/6] quit
[DeviceA] interface gigabitethernet 1/0/7
[DeviceA-GigabitEthernet1/0/7] port link-aggregation group 5
[DeviceA-GigabitEthernet1/0/7] quit
```

Add Layer 2 aggregate interface Bridge-Aggregation 5 to VLAN 10, and configure the interface as an M-LAG interface.

```
[DeviceA] interface bridge-aggregation 5
[DeviceA-Bridge-Aggregation5] port access vlan 20
[DeviceA-Bridge-Aggregation5] port m-lag group 5
[DeviceA-Bridge-Aggregation5] quit
```

2. Configure Device B in the same way Device A is configured.

3. Configure Device C.

Create Layer 2 aggregate interface Bridge-Aggregation 4 and set the aggregation mode to dynamic.

```
<DeviceC> system-view
[DeviceC] interface bridge-aggregation 4
[DeviceC-Bridge-Aggregation4] link-aggregation mode dynamic
[DeviceC-Bridge-Aggregation4] quit
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to aggregation group 4.

```
[DeviceC] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[DeviceC-if-range] port link-aggregation group 4
[DeviceC-if-range] quit
```

Add Layer 2 aggregate interface Bridge-Aggregation 4 to VLAN 100.

```
[DeviceC] interface bridge-aggregation 4
[DeviceC-Bridge-Aggregation4] port access vlan 10
[DeviceC-Bridge-Aggregation4] quit
```

Add GigabitEthernet 1/0/5 through GigabitEthernet 1/0/7 to VLAN 10.

```
[DeviceC] interface range gigabitethernet 1/0/5 to gigabitethernet 1/0/7
[DeviceC-if-range] port access vlan 10
[DeviceC-if-range] quit
```

4. Configure Device D in the same way Device C is configured.

Configuring portal authentication

1. Configure Device A.

a. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<DeviceA> system-view
[DeviceA] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[DeviceA-radius-rs1] primary authentication 192.168.0.112
[DeviceA-radius-rs1] primary accounting 192.168.0.112
[DeviceA-radius-rs1] key authentication simple radius
[DeviceA-radius-rs1] key accounting simple radius
```

Exclude the ISP domain name from the username sent to the RADIUS server.

```
[DeviceA-radius-rs1] user-name-format without-domain
[DeviceA-radius-rs1] quit
```

b. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[DeviceA] domain dm1
```

Configure AAA methods for the ISP domain.

```
[DeviceA-isp-dm1] authentication portal radius-scheme rs1
[DeviceA-isp-dm1] authorization portal radius-scheme rs1
[DeviceA-isp-dm1] accounting portal radius-scheme rs1
[DeviceA-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[DeviceA] domain default enable dm1
```

c. Configure portal authentication:

Configure a portal authentication server.

```
[DeviceA] portal server newpt
[DeviceA-portal-server-newpt] ip 192.168.0.111 key simple portal
[DeviceA-portal-server-newpt] port 50100
[DeviceA-portal-server-newpt] quit
```

Configure a portal Web server.

```
[DeviceA] portal web-server newpt
[DeviceA-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[DeviceA-portal-websvr-newpt] quit
```

Enable direct portal authentication on VLAN-interface 100.

```
[DeviceA] interface vlan 10
[DeviceA–Vlan-interface10] portal enable method direct
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[DeviceA–Vlan-interface10] portal apply web-server newpt
```

Configure the BAS-IP as 2.2.2.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

```
[DeviceA–Vlan-interface10] portal bas-ip 2.2.2.1
[DeviceA–Vlan-interface10] quit
```

Set the authentication load sharing mode to distributed and set the distribution criterion to even-IP.

```
[DeviceA] portal m-lag load-sharing-mode distributed even-ip
```

2. Configure Device B.

Set the authentication load sharing mode to distributed and set the distribution criterion to odd-IP.

```
[DeviceB] portal m-lag load-sharing-mode distributed odd-ip
```

Configure other configuration on Device B in the same way Device A is configured.

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[DeviceA] display portal interface vlan-interface 10
 Portal information of Vlan-interface10
     NAS-ID profile: Not configured

Troubleshooting portal

No portal authentication page is pushed for users

Symptom

When a user is redirected to the IMC portal authentication server, no portal authentication page or error message is prompted for the user. The login page is blank.

Analysis

The key configured on the portal access device and that configured on the portal authentication server are inconsistent. As a result, packet verification fails, and the portal authentication server refuses to push the authentication page.

Solution

Use the **display this** command in portal authentication server view on the access device to check whether a key is configured for the portal authentication server.

- If no key is configured, configure the right key.
- If a key is configured, use the **ip** or **ipv6** command in the portal authentication server view to correct the key, or correct the key configured for the access device on the portal authentication server.

Cannot log out portal users on the access device

Symptom

You cannot use the **portal delete-user** command on the access device to log out a portal user, but the portal user can log out by clicking the **Disconnect** button on the portal authentication client.

Analysis

When you execute the **portal delete-user** command on the access device to log out a user, the access device sends an unsolicited logout notification message to the portal authentication server. The destination port number in the logout notification is the listening port number of the portal authentication server configured on the access device. If this listening port number is not the actual listening port number configured on the server, the server cannot receive the notification. As a result, the server does not log out the user.

When a user uses the **Disconnect** button on the authentication client to log out, the portal authentication server sends an unsolicited logout request message to the access device. The access device uses the source port in the logout request as the destination port in the logout ACK message. As a result, the portal authentication server can definitely receive the logout ACK message and log out the user.

Solution

1. Use the **display portal server** command to display the listening port of the portal authentication server configured on the access device.
2. Use the **portal server** command in system view to change the listening port number to the actual listening port of the portal authentication server.

Cannot log out portal users on the RADIUS server

Symptom

The access device uses the IMC server as the RADIUS server to perform identity authentication for portal users. You cannot log out the portal users on the RADIUS server.

Analysis

The IMC server uses session control packets to send disconnection requests to the access device. On the access device, the listening UDP port for session control packets is disabled by default. Therefore, the access device cannot receive the portal user logout requests from the RADIUS server.

Solution

On the access device, execute the **radius session-control enable** command in system view to enable the RADIUS session control function.

Users logged out by the access device still exist on the portal authentication server

Symptom

After you log out a portal user on the access device, the user still exists on the portal authentication server.

Analysis

When you execute the **portal delete-user** command on the access device to log out a user, the access device sends an unsolicited logout notification to the portal authentication server. If the

BAS-IP or BAS-IPv6 address carried in the logout notification is different from the portal device IP address specified on the portal authentication server, the portal authentication server discards the logout notification. When sending of the logout notifications times out, the access device logs out the user. However, the portal authentication server does not receive the logout notification successfully, and therefore it regards the user is still online.

Solution

Configure the BAS-IP or BAS-IPv6 attribute on the interface enabled with portal authentication. Make sure the attribute value is the same as the portal device IP address specified on the portal authentication server.

Re-DHCP portal authenticated users cannot log in successfully

Symptom

The device performs re-DHCP portal authentication for users. A user enters the correct username and password, and the client successfully obtains the private and public IP addresses. However, the authentication result for the user is failure.

Analysis

When the access device detects that the client IP address is changed, it sends an unsolicited portal packet to notify of the IP change to the portal authentication server. The portal authentication server notifies of the authentication success only after it receives the IP change notification from both the access device and the client.

If the BAS-IP or BAS-IPv6 address carried in the portal notification packet is different from the portal device IP address specified on the portal authentication server, the portal authentication server discards the portal notification packet. As a result, the portal authentication server considers that the user has failed the authentication.

Solution

Configure the BAS-IP or BAS-IPv6 attribute on the interface enabled with portal authentication. Make sure the attribute value is the same as the portal device IP address specified on the portal authentication server.

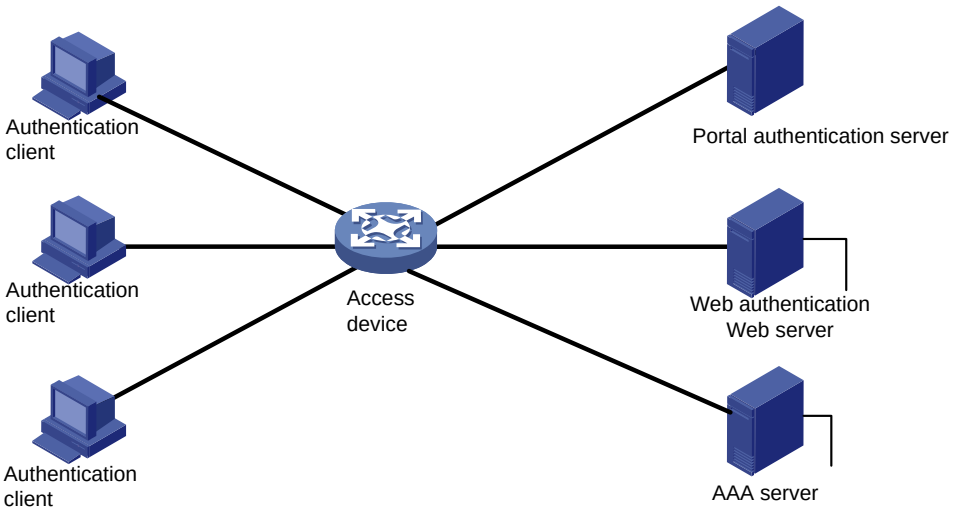
Configuring Web authentication

About Web authentication

Web authentication is deployed on Layer 2 interfaces of the access device to control user access to networks. The access device redirects unauthenticated users to the specified website. The users can access the resources on the website without authentication. If the users want to access other network resources, they must pass authentication.

Advantages of Web authentication



Web authentication has the following advantages:

- Allows users to perform authentication through webpages without installing client software.
- Provides ISPs with diversified management choices and extended functions. For example, the ISPs can place advertisements, provide community services, and publish information on the authentication page.

Web authentication system

A typical Web authentication system consists of the following basic components: authentication client, access device, Web server for Web authentication, portal authentication server, and AAA server.

Figure 1 Web authentication system using the local portal server

Authentication client

An authentication client is a Web browser that runs HTTP or HTTPS on the user endpoint.

Access device

An access device has the following functions:

- Redirects all user HTTP or HTTPS requests that do not match authentication-free rules to the Web authentication page before authentication.
- Interacts with the AAA server to complete authentication, authorization, and accounting. For more information about AAA, see "Configuring AAA."

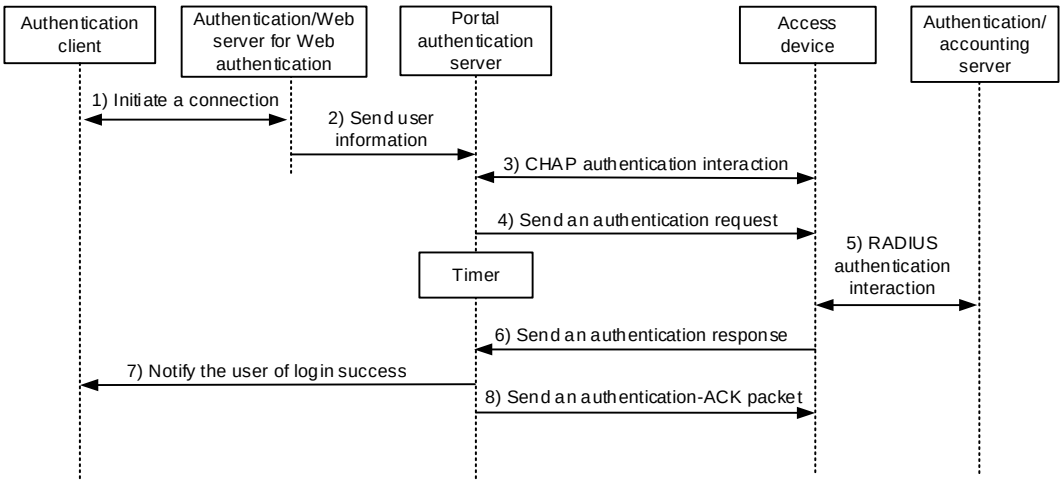
- Allows users that pass authentication to access authorized network resources.

Web server for Web authentication

A Web server pushes the Web authentication page to authentication clients and obtains user authentication information (username and password).

A Web server for Web authentication can be a local Web server or a remote Web server. A local Web server is usually integrated into the access device. A remote Web server is a portal Web server.

Portal authentication server



Web authentication uses a portal authentication server as the authentication server, which exchanges client authentication information with the access device.

AAA server

An AAA server interacts with the access device to implement user authentication, authorization, and accounting. A RADIUS server can perform authentication, authorization, and accounting for Web authentication users. An LDAP server can perform authentication for Web authentication users.

Web authentication process

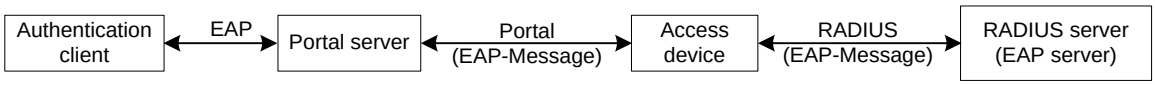
Figure 2 Web authentication process

The Web authentication process is as follows:

1. An unauthenticated user sends an HTTP or HTTPS request. When the access device receives the HTTP or HTTPS request on a Layer 2 Ethernet interface enabled with Web authentication, the request, it redirects the request to the Web authentication page. The user enters the username and password on the Web authentication page.

   If the user requests the Web authentication page or free Web resources, the access device permits the request. No Web authentication is performed.
2. The Web server for Web authentication sends the user information to the portal authentication.
3. The portal authentication server and the access device interact with each other to perform CHAP authentication. This step is skipped if PAP authentication is used. The authentication interaction type is determined by the portal authentication server.
4. The portal authentication sends an authentication request that contains the username and password of the user to the access device and starts a timer to wait for an authentication response.
5. The access device and the AAA server exchange RADIUS packets to authenticate the user.

6. The access device sends an authentication response indicating authentication success or failure to the portal authentication server.
7. The portal authentication server notifies the authentication result to the client.
8. If the user passes RADIUS authentication, the portal authentication server also sends an authentication-ACK packet to the access device.



Web authentication support for EAP

This feature is supported only when Web authentication uses a remote IMC portal authentication server and an iNode portal client.

Compared with username and password based authentication, digital certificate-based authentication ensures higher security.

The Extensible Authentication Protocol (EAP) supports several digital certificate-based authentication methods, for example, EAP-TLS. Working together with EAP, Web authentication can implement digital certificate-based user authentication.

Figure 3 Web authentication support for EAP protocol exchanges

As shown in Figure 3, the authentication client and the portal authentication server exchange EAP authentication packets. The portal authentication server and the access device exchange portal authentication packets that carry the EAP-Message attributes. The access device and the RADIUS server exchange RADIUS packets that carry the EAP-Message attributes. The RADIUS server that supports the EAP server function processes the EAP packets encapsulated in the EAP-Message attributes, and provides the EAP authentication result.

The access device does not process but only transports EAP-Message attributes between the portal authentication server and the RADIUS server. Therefore, the access device requires no additional configuration to support EAP authentication.

Web authentication support for VLAN assignment

Authorization VLAN

Web authentication uses VLANs authorized by the AAA server or the access device to control network resource access of authenticated users. The authorization VLAN information includes VLAN ID and VLAN name.

After a user passes Web authentication, the AAA server or the access device authorizes the user to access a VLAN. If the authorization VLAN does not exist, the access device first creates the VLAN and then assigns the user access interface as an untagged member to the VLAN. If the authorization VLAN already exists, the access device directly assigns the user access interface as an untagged member to the VLAN. Then, the user can access resources in the authorization VLAN.

Table 1 describes the way the access device handles authorization VLANs for Web authenticated users.

Table 1 VLAN manipulation

Port type	VLAN manipulation
• Access port • Trunk port • Hybrid port with MAC-based-VLAN disabled	The device assigns the port to the first authenticated user's authorization VLAN. The authorization VLAN becomes the PVID. All Web authentication users on the port must be assigned the same authorization VLAN. If a different authorization VLAN is assigned to a subsequent user, the user cannot pass Web authentication.

Port type	VLAN manipulation
Hybrid port with MAC-based VLAN enabled	The device maps the MAC address of each user to its own authorization VLAN regardless of whether the port is a tagged member. The PVID of the port does not change.

Auth-Fail VLAN

An Auth-Fail VLAN is a VLAN assigned to users who fail authentication. The Auth-Fail VLAN provides network resources such as the patch server, virus definitions server, client software server, and anti-virus software server to the users. The users can use these resources to upgrade their client software or other programs.

Web authentication supports Auth-Fail VLAN on an interface that performs MAC-based access control. If a user on the interface fails authentication, the access devices creates a MAC VLAN entry based on the MAC address of the user and adds the user to the Auth-Fail VLAN. Then, the user can access the authentication-free IP resources in the Auth-Fail VLAN. All HTTP or HTTPS requests to non-authentication-free IP resources will be redirected to the authentication page. If the user still fails authentication, the interface remains in the Auth-Fail VLAN. If the user passes authentication, the access device removes the interface from the Auth-Fail VLAN and assigns the interface to a VLAN as follows:

- If the authentication server assigns an authorization VLAN to the user, the access device assigns the interface to the authorization VLAN.
- If the authentication server does not assign an authorization VLAN to the user, the access device assigns the interface to the default VLAN.

Web authentication multi-VLAN mode

Web authentication supports single-VLAN or multi-VLAN mode on a port.

In multi-VLAN mode, the port forwards traffic from a user in different VLANs without reauthentication if the user has been authenticated and come online in any VLAN on the port.

In single-VLAN mode, the port reauthenticates an online user when traffic received from that user contains a VLAN tag different from the VLAN in which the user was authenticated. The authentication process differs depending on the MAC move setting in port security and the authorization VLAN assignment status, as follows:

- If no authorization VLAN has been assigned to the online user, the device first logs off the user and then reauthenticates the user in the new VLAN.
- If the online user has been assigned an authorization VLAN, the device handles the user depending on the MAC move setting in port security.
  - If MAC move is disabled in port security, the user cannot pass authentication and come online from the new VLAN until after it goes offline from the port.
  - If MAC move is enabled in port security, the user can pass authentication on the new VLAN and come online without having to first go offline from the port. After the user passes authentication on the new VLAN, the original authentication session of the user is deleted from the port.

  To enable the port security MAC move feature, use the **`port-security mac-move permit`** command.

Web authentication support for authorization ACLs

Web authentication uses ACLs authorized by the AAA server or the access device to control user access to network resources and limit user access rights. When a user passes authentication, the AAA server and the access device assigns an authorization ACL to the access interface of the user. The access device filters traffic from the user on the access interface according to the authorized ACL.

You must configure the authorization ACLs on the access device if you specify authorization ACLs on the authentication server.

To change the access control criteria for the user, you can specify a different authorization ACL on the authentication server or change rules in the authorization ACL on the access device.

The device supports the following types of authorization ACLs:

- Basic ACLs (ACL 2000 to ACL 2999).
- Advanced ACLs (ACL 3000 to ACL 3999).
- Layer 2 ACLs (ACL 4000 to ACL 4999).

For an authorization ACL to take effect, make sure the ACL exists and has ACL rules excluding rules configured with the **`counting`**, **`established`**, **`fragment`**, **`source-mac`**, or **`logging`** keyword. For more information about ACL rules, see ACL commands in *ACL and QoS Command Reference*.

In a microsegment network, if a user is assigned both an authorization microsegment and ACL, the authorization ACL does not take effect.

Web authentication support for microsegment assignment

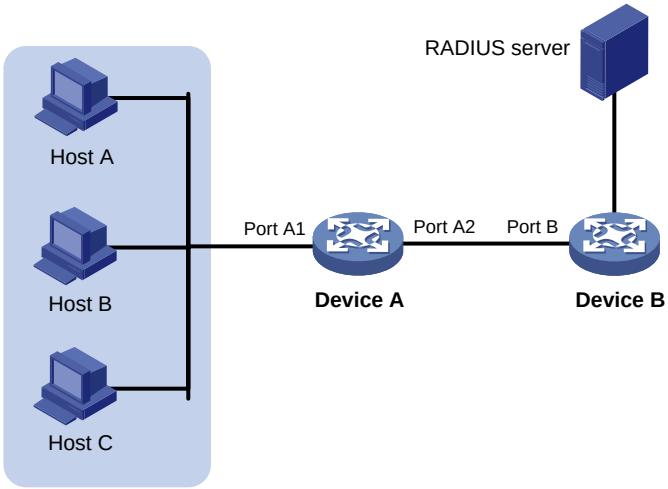
To implement fine-grained isolation of Web authentication user traffic, users are usually assigned to different groups based on their business requirements for group-based user access control. The IDs of the groups are called microsegments, which can be assigned to users by the RADIUS server. When a user comes online, the RADIUS server assigns an authorization microsegment to the user. The access device filters traffic from the user on the access port according to the authorization microsegment. The user can access the network resources in the microsegment.

In a non-microsegment network, do not configure authorization microsegments for users.

Restrictions and guidelines: Web authentication configuration

When you configure Web authentication, follow these restrictions and guidelines:

- Web authentication cannot be configured in conjunction with the following 802.1X settings:
  - Guest, Auth-Fail, and critical VLAN settings.
  - Guest, Auth-Fail, and critical VSI settings.
  - Critical microsegment settings.
- Web authentication cannot be configured in conjunction with the following MAC authentication settings:
  - Guest and critical VLAN settings.
  - Guest and critical VSI settings.
  - Critical microsegment settings.
- Auth-Fail VLAN is mutually exclusive with the port security preauthentication domain feature.



To redirect HTTPS requests for unauthenticated users correctly, make sure the packet incoming VLANs or VSIs have Layer 3 interfaces (VLAN or VSI interfaces) configured.

To access the resources in the authorization VLAN or Auth-Fail VLAN, a user must update the IP address of the client after being assigned to the authorization VLAN or Auth-Fail VLAN.

As a best practice, perform Web authentication on users directly connected to the device. As shown in Figure 4, if you enable Web authentication on Port B to authenticate non-directly connected users (the hosts), you must follow these restrictions and guidelines:

- If the RADIUS server assigns an authorization VLAN to the users, make sure the following conditions are met:
  - The link between Device A and Device B is a trunk link.
  - The PVIDs of Port A1 and Port B are the same as the authorization VLAN ID.
- If the RADIUS server does not assign an authorization VLAN to the users, make sure the PVIDs of Port A1 and Port B are the same.

Figure 4 Web authentication for non-directly connected users

Web authentication tasks at a glance

To configure Web authentication, perform the following tasks:

1. Configuring a remote Web authentication service

   Perform this task if a remote Web server is deployed on the network for Web authentication.

   a. Configuring a remote portal authentication server
   b. Configuring a remote Web server for Web authentication
   c. Obtaining user information from ARP or ND entries
2. Configuring a local Web authentication service

   Perform this task if the device is used as the local Web server for Web authentication.

   a. Configuring a local Web server for Web authentication
   b. Configuring a local portal service
3. Enabling Web authentication
4. (Optional.) Specifying a Web authentication domain
5. (Optional.) Setting the redirection wait time
6. (Optional.) Configuring the aging timer for temporary MAC address entries
7. (Optional.) Configuring Web authentication-free subnets or host names
8. (Optional.) Setting the maximum number of Web authentication users
9. (Optional.) Configuring online Web authentication user detection
10. (Optional.) Enabling online detection bypass for Web authentication users
11. (Optional.) Configuring an Auth-Fail VLAN
12. (Optional.) Configuring Web authentication to support Web proxy
13. Applying a portal MAC binding server for Web authentication

    This task is required to perform the MAC-based quick authentication.

14. (Optional.) Enabling Web authentication user logging

Prerequisites for Web authentication

The device supports two methods for Web authentication, which are local authentication and RADIUS authentication.

To use the RADIUS authentication method, you must complete the following tasks:

- Install a RADIUS server and configure the RADIUS server properly.
- Make sure the authentication client, the access device, and the RADIUS server can reach each other.
- Configure user accounts on the RADIUS server and configure the RADIUS client information on the access device.

To use the local authentication method, you must configure local users on the access device.

For more information about RADIUS clients and local users, see "Configuring AAA."

Configuring a remote Web server for Web authentication

About this task

In the view of a remote Web server, you can configure the Web server IP address, redirection URL, and the parameters to be carried in the redirection URL.

By default, the state of the Web server specified by the redirection URL is always **active**. The device cannot obtain the real server state. When primary and secondary Web servers are deployed for continuous authentication service, the device needs to quickly obtain the primary server's state changes to perform primary/secondary switchovers accordingly.

You can associate the Web server with a track entry that is associated with NQA, so the device can periodically detect the reachability of the server through NQA.

- The Track module changes the state of the track entry according to the NQA detection result. The device changes the state of the Web server according to the state of the track entry.
- In this way, if NQA detects that the Web server becomes reachable, the device will set the server state to active. If NQA detects that the Web server becomes unreachable, the device will set the server state to inactive.

For more information about the Track configuration, see *High Availability Configuration Guide*.

Restrictions and guidelines

To deploy both primary and secondary Web servers, you must associate the primary Web server with a track entry to monitor the reachability status of the server. Otherwise, the device cannot sense the reachability state changes of the primary server to perform primary/secondary switchovers.

The NQA detection for server reachability is performed according to the **`nqa schedule`** configuration, which schedules the NQA operation associated with the track entry. Configure the NQA operation time and other detection parameters as needed.

Procedure

1. Enter system view.

   `system-view`

2. Create a remote Web server for Web authentication and enter Web authentication remote Web server view.

web-auth remote server *server-name*

The local and remote Web servers cannot use the same name.

3. Specify the IP address of the remote Web server for Web authentication.

   IPv4:

   ip *ipv4-address*

   IPv6:

   ipv6 *ipv6-address*

   By default, no IP address is specified for the remote Web server for Web authentication.

   The IP address of the remote Web server must be the IP address of the portal Web server used for Web authentication.

   You can configure one IPv4 address and one IPv6 address for a remote Web server.

4. Configure the redirection URL of the remote Web server for Web authentication.

   url *url-string* [**track** *track-entry-number*]

   By default, no redirection URL is specified for a Web server for Web authentication.

   To provide Web authentication pages for both IPv4 and IPv6 Web authentication users, configure the redirection URL to carry the domain name of the Web server. For example: **https://example.com**, where **example.com** is the domain name of the Web server.

   A Web server can be associated with only one track entry. If you associate Track with the Web server multiple times, the most recent configuration takes effect.

5. (Optional.) Add parameters to the redirection URL of the remote Web server.

   url-parameter *parameter-name* { **original-url** | **source-address** | **source-mac** | **value** *expression* }

   By default, no parameters are added to the redirection URL of a Web server.

   You must use the URL parameter name supported by the Web browser. Different Web browsers support different URL parameter names.

6. (Optional.) Configure the unescaped special characters in the Web authentication URL redirected to users.

   url-unescape-chars *character-string*

   By default, the device escapes all special characters in the Web authentication URL redirected to users.

7. (Optional.) Configure the Web server to support the Oasis platform.

   server-type oauth

   By default, a Web authentication server does not support the Oasis platform.

   To use an Oasis server as a Web authentication server, execute this command to support the Oasis platform.

Configuring a remote portal authentication server

For information about configuring a remote portal authentication server, see "Configuring portal authentication."

Obtaining user information from ARP or ND entries

About this task

By default, the device obtains user information required by the portal authentication server from MIB entries. However, MIB entries do not contain the Layer 2 user information (such as MAC address and Layer 2 access interface) required for Web authentication. Users will fail the Web authentication as a result.

To resolve this issue, configure the device to obtain user information from ARP or ND entries.

Procedure

1. Enter system view.

   system-view

2. Configure the device to obtain portal user information from ARP or ND entries.

   portal access-info trust { **arp** | **nd** }

   By default, the device obtains user information from FIB entries.

   For more information about the configuration, see "Configuring portal authentication."

Configuring a local Web server for Web authentication

Restrictions and guidelines

Specify the IP address of a Layer 3 interface on the device that is routable to the Web client as the listening IP address of the local Web server for Web authentication. As a best practice, use the IP address of a loopback interface. A loopback interface has the following advantages:

- The status of a loopback interface is stable. There will be no authentication page access failures caused by interface failures.
- A loopback interface does not forward received packets to any networks, avoiding impact on system performances when there are many network access requests.

Procedure

1. Enter system view.

   system-view

2. Create a local Web server for Web authentication and enter Web authentication local Web server view.

   web-auth server *server-name*

   The local and remote Web servers cannot use the same name.

3. Specify the IP address and port number of the local Web server.

   IPv4:

   ip *ipv4-address* **port** *port-number*

   IPv6:

   ipv6 *ipv6-address* **port** *port-number*

   The port number of the local Web server must be the same as the listening port number of the local portal Web service.

   You can configure one IPv4 address and one IPv6 address for a local Web server.

4. Specify the redirection URL for the local Web server.

   url *url-string*

   By default, no redirection URL is specified for a Web server for Web authentication.

   The redirection URL must start with **http://** or **https://**. The IP address and port number in the specified redirection URL must be the same as those of the local Web server for Web authentication.

   To provide Web authentication pages for both IPv4 and IPv6 Web authentication users, configure the redirection URL to carry the domain name of the Web server.

5. (Optional.) Add parameters to the redirection URL of the local Web server.

   url-parameter *parameter-name* { **original-url** | **source-address** | **source-mac** | **value** *expression* }

   By default, no parameters are added to the redirection URL of a Web server.

   You must use the URL parameter name supported by the Web browser. Different Web browsers support different URL parameter names.

6. (Optional.) Configure the unescaped special characters in the Web authentication URL redirected to users.

   url-unescape-chars *character-string*

   By default, the device escapes all special characters in the Web authentication URL redirected to users.

7. (Optional.) Configure the Web server to support the Oasis platform.

   server-type oauth

   By default, a Web authentication server does not support the Oasis platform.

   To use an Oasis server as a Web authentication server, execute this command to support the Oasis platform.

Configuring a local portal service

For information about the local portal service configuration, see "Configuring portal authentication."

Enabling Web authentication

Restrictions and guidelines

For Web authentication to operate correctly, do not enable port security or configure the port security mode on the Layer 2 interface enabled with Web authentication. For more information about port security, see "Configuring port security."

To deploy both primary and secondary Web servers, follow these restrictions and guidelines:

- Only a remote Web server can be used as the primary Web server. A remote or local Web server can be used as the secondary Web server.
- Associate the primary Web server with a track entry (by using the **url** *url-string* **track** *track-entry-number* command) to monitor the reachability status of the server. Otherwise, the device cannot sense the reachability state changes of the primary server to perform primary/secondary switchovers.

The default HTTPS redirect listening port number on the device is 6654. To change the HTTPS redirect listening port number, see HTTP redirect configuration in *Layer 3—IP Services Configuration Guide*.

Procedure

1. Enter system view.

system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable Web authentication and specify Web servers for Web authentication.

   web-auth enable apply server *primary-server-name* [**secondary-server** *secondary-server-name*]

   By default, Web authentication is disabled.

Specifying a Web authentication domain

About this task

You can specify different authentication domains for Web authentication users on different interfaces. After you specify a Web authentication domain on an interface, the device uses the authentication domain for AAA of all Web authentication users on the interface, ignoring the domain names carried in the usernames.

The device selects the authentication domain for a Web authentication user on an interface in this order:

1. The authentication domain specified for the interface.
2. The authentication domain carried in the username.
3. The system default authentication domain.
4. The ISP domain configured to accommodate users assigned to nonexistent domains.

If the selected domain does not exist on the device, user authentication fails. For information about ISP domains, see "Configuring AAA."

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify an authentication domain for Web authentication users on the interface.

   web-auth domain *domain-name*

   By default, no authentication domain is specified for Web authentication users.

Setting the redirection wait time

About this task

The redirection wait time determines the length of time that the device waits to redirect a user to the specified webpage after the user passes Web authentication.

You need to change the redirection wait time in some scenarios, for example, when a user needs to update the client IP address after passing local Web authentication. To ensure that the specified webpage can be successfully opened, set the redirection wait time to be greater than the time that the user takes to update the IP address of the client.

Procedure

1. Enter system view.

   system-view

2. Enter Web authentication local Web server view.

web-auth server *server-name*

3. Set the redirection wait time.

   redirect-wait-time *period*

   By default, the redirection wait time for authenticated users is 5 seconds.

Configuring the aging timer for temporary MAC address entries

About this task

If Web authentication is enabled, the device generates a temporary MAC address entry when it detects traffic from a user for the first time. The entry records the MAC address, access interface, and VLAN ID of the user, as well as the aging time of the entry.

The aging timer works as follows:

- If the user does not initiate authentication when the aging timer expires, the device deletes the temporary entry.
- If the user passes authentication before the aging timer expires, the device deletes the aging timer and records online information for the Web authentication user.
- If the user fails authentication before the aging timer expires and an Auth-Fail VLAN is specified for Web authentication, the device binds the MAC address of the user to the Auth-Fail VLAN and reset the aging timer. If the user still fails authentication when the aging timer expires, the device deletes the temporary entry for the user.

Restrictions and guidelines

As a best practice, change the aging timer to a bigger value in the following cases:

- Web authentication users without access rights frequently send traffic in a short time. As a result, the access device continuously initiates the web authentication process, increasing the load on the device.
- When a user fails authentication, the user does not have enough time to obtain resources from the Auth-Fail VLAN, for example, it failed to download the virus patches.

Procedure

1. Enter system view.

   system-view

2. Configure the aging timer for temporary MAC address entries.

   web-auth timer temp-entry-aging *aging-time-value*

   By default, the aging timer for temporary MAC address entries is 60 seconds.

Configuring Web authentication-free subnets or host names

Configuring a Web authentication-free subnet

About this task

You can configure a Web authentication-free subnet so that users can freely access the network resources in the subnet without being authenticated.

Restrictions and guidelines

As a best practice, do not configure the same address value for a Web authentication-free subnet and a 802.1X free IP. Otherwise, when you cancel one of the configuration, the other configuration does not take effect, either.

Procedure

1. Enter system view.

   system-view

2. Configure a Web authentication-free subnet.

   web-auth free-ip *ip-address* { *mask-length* | *mask* }

   By default, no Web authentication-free subnets exist.

Configuring a Web authentication-free host name

About this task

You can configure Web authentication-free host names so that users can freely access the specified host resources without being authenticated.

Restrictions and guidelines

Web authentication-free host names support only precise matching. For example, Web authentication-free host name **abc.com.cn** matches only HTTP/HTTPS request packets that contain the host name of **abc.com.cn**. It does not match packets that contain host name **dfabc.com.cn**.

Prerequisites

Before configuring Web authentication-free destination host names, make sure a DNS server has been deployed on the network, or the host name-to-IPv4 address mappings have been configured by using the **ip host** command. For more information about the **ip host** command, see DNS commands in *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Configure a Web authentication-free host name.

   web-auth free-host *host-name*

   By default, no Web authentication-free host names exist.

Setting the maximum number of Web authentication users

Restrictions and guidelines

If the maximum number of online Web authentication users you set is less than that of the current online Web authentication users, the limit can be set successfully and does not impact the online Web authentication users. However, the system does not allow new Web authentication users to log in until the number drops down below the limit.

Procedure

1. Enter system view.

system-view

2. Enter interface view.
   interface *interface-type interface-number*
3. Set the maximum number of Web authentication users on the interface.
   web-auth max-user [**preauth-domain** | **auth-fail-domain**] *max-number*
   By default, the maximum number of Web authentication users is 1024.

Configuring online Web authentication user detection

About this task

This feature enables the device to detect packets of an online user at the specified detection interval. If no packet from the user is received within the interval, the device logs out the user and notifies the RADIUS server to stop accounting for the user.

Restrictions and guidelines

To prevent the device from mistakenly logging out users, set the detection interval to be the same as the aging time of MAC address entries.

On a Layer 2 aggregate interface, the real interval for logging out a user is greater than the specified detection interval. The maximum delay is 300 seconds.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable online Web authentication user detection.
   web-auth offline-detect interval *interval*
   By default, online Web authentication user detection is disabled.

Enabling online detection bypass for Web authentication users

About this task

By default, when all RADIUS servers in the ISP domain are unreachable and online Web authentication user detection is enabled, the device logs out the Web authentication users.

Enable online detection bypass for Web authentication users if you want to use online Web authentication user detection but retain the online users when all RADIUS servers are unreachable.

With online detection bypass enabled for Web authentication users, when all the RADIUS servers are unreachable, the device automatically disables online Web authentication user detection to keep the users online.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.

interface *interface-type interface-number*

3. Enable online detection bypass for Web authentication users.

   web-auth auth-server-unavailable escape

   By default, online detection bypass for Web authentication users is disabled when no RADIUS servers are reachable.

Configuring an Auth-Fail VLAN

Restrictions and guidelines

To make the Auth-Fail VLAN take effect, you must also enable MAC-based VLAN on the interface, and set the subnet of the Auth-Fail VLAN as the Web authentication-free subnet.

Because MAC-based VLAN takes effect only on Hybrid ports, Auth-Fail VLAN also takes effect only on Hybrid ports.

If a VLAN is specified as the super VLAN, do not configure the VLAN as an Auth-Fail VLAN of an interface. If a VLAN is specified as an Auth-Fail VLAN of an interface, do not configure the VLAN as a super VLAN.

Do not delete the VLAN that has been configured as an Auth-Fail VLAN. To delete this VLAN, first cancel the Auth-Fail VLAN configuration by using **undo web-auth auth-fail vlan** command.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure an Auth-Fail VLAN.

   web-auth auth-fail vlan *authfail-vlan-id*

   By default, no Auth-Fail VLAN is configured on an interface.

Configuring Web authentication multi-VLAN mode

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the multi-VLAN mode for Web authentication on the port.

   web-auth host-mode multi-vlan

   By default, Web authentication operates in single-VLAN mode on a port.

Configuring Web authentication to support Web proxy

About this task

By default, proxied HTTP or HTTPS requests cannot trigger Web authentication but are silently dropped. To allow such HTTP or HTTPS requests to trigger Web authentication, specify the port numbers of the Web proxy servers on the device.

Restrictions and guidelines

If a user's browser uses the Web Proxy Auto-Discovery (WPAD) protocol to discover Web proxy servers, follow these restrictions and guidelines:

- Add the port numbers of the Web proxy servers on the device.
- Configure a Web authentication-free rule on the device to allow user packets destined for the IP address of the WPAD server to pass without authentication.
- Users must add the IP address of the Web server for Web authentication as a proxy exception in their browsers. Then, HTTP or HTTPS packets that the users send to the Web server for Web authentication will not be sent to Web proxy servers.

Procedure

1. Enter system view.

   system-view

2. Add a Web proxy server port number.

   web-auth proxy [**https**] **port** *port-number*

   By default, no Web proxy server port numbers are configured on the device.

   Do not specify port number 80 or 443 because 80 and 443 are port numbers reserved for Web authentication.

   Do not specify the same Web proxy server port number for HTTP and HTTPS.

Applying a portal MAC binding server for Web authentication

About this task

In Web authentication scenarios where valid users need to frequently access the network, you can configure MAC-based quick authentication to allow the users to pass Web authentication without manually entering the authentication information.

MAC-based quick authentication is also called MAC-trigger authentication or transparent authentication. It requires a portal MAC binding server.

When a user accesses the network, the access device sends the user's MAC address in a query message to the portal MAC binding server. If the portal MAC binding server finds user authentication information bound to the MAC address, it sends the user authentication information to the access device to initiate Web authentication. The user is authenticated without entering the username and password.

Restrictions and guidelines

This feature supports only IPv4 portal MAC binding servers, and the server type must be Oasis platform.

To make the MAC-based quick authentication take effect, complete the following tasks:

- Complete the normal Layer 2 Web authentication configuration.
- Configure the IP address and port number of the portal MAC binding server to be used.
- Apply the portal MAC binding server to a Layer 2 Ethernet interface or Layer 2 aggregate interface.

Prerequisites

Before applying a portal MAC binding server for Web authentication, deploy the portal MAC binding server on the network.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Apply a portal MAC binding server to the interface.
   web-auth apply portal mac-trigger-server *server-name*
   By default, no portal MAC binding server is applied for Web authentication.

Enabling Web authentication user logging

About this task

Web authentication user logs can help troubleshoot and solve issues. This feature enables the device to generate logs about Web authentication users and send the logs to the information center. For the logs to be output correctly, you must also configure the information center on the device. With the information center, you can configure log output destinations and output rules. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Outputting a large number of Web authentication user logs might degrade device performance. As a best practice, enable Web authentication user logging only when necessary.

Procedure

1. Enter system view.
   system-view
2. Enable Web authentication user logging.
   web-auth access-user log enable [**abnormal-logoff** | **failed-login** | **normal-logoff** | **successful-login**] *
   By default, Web authentication user logging is disabled.

Display and maintenance commands for Web authentication

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display Web authentication configuration information on interfaces.	**display web-auth** [**interface** *interface-type interface-number*]
Display Web authentication-free subnets.	**display web-auth free-ip**

Task	Command
Display information about Web servers for Web authentication.	**display web-auth server** [*server-name*]
Display Web authentication user information.	**display web-auth user** [**m-lag** [**local** | **peer**]] [**interface** *interface-type interface-number* | **slot** *slot-number*]
Log off Web authentication users.	**reset web-auth access-user** [**interface** *interface-type interface-number* | **mac** *mac-address* | **username** *username*]

Web authentication configuration examples

Example: Configuring local Web authentication by using the AAA local authentication method

Network configuration

As shown in Figure 5, the host is directly connected to the device through GigabitEthernet 1/0/1.

Configure local Web authentication on GigabitEthernet 1/0/1, and configure the device to perform local authentication and authorization for the local Web authentication users.

Configure a local Web server on the device that uses the IP address of Loopback 0 and port 80 for Web authentication. Configure the device to use HTTP to transfer the authentication data.

Figure 5 Network diagram

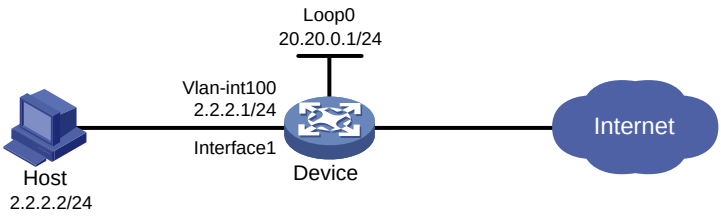


Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Prerequisites

Create VLANs, assign IP addresses to the VLAN interfaces, and assign interfaces to the VLANs.

Procedure

1. Configure a local user:

   # Create a local network access user named **localuser**.

   ```
   <Device>system-view
   [Device] local-user localuser class network
   ```

   # Set the password for user **localuser.**

   ```
   [Device-luser-network-localuser] password simple 123456TESTplat&!
   ```

   # Authorize the user to use LAN access services.

```
[Device-luser-network-localuser] service-type lan-access
[Device-luser-network-localuser] quit
```

2. Configure an ISP domain:

Create an ISP domain named **local**.

```
[Device] domain local
```

Configure the ISP domain to perform local authentication, authorization, and accounting for LAN access users.

```
[Device-isp-local] authentication lan-access local
[Device-isp-local] authorization lan-access local
[Device-isp-local] accounting lan-access local
[Device-isp-local] quit
```

3. Configure a local portal Web service:

Create an HTTP-based local portal Web service and enter its view.

```
[Device] portal local-web-server http
```

Specify file **defaultfile.zip** as the default authentication page file for the local portal Web service. (Make sure the authentication page file already exists in the root directory of the storage medium on the device.)

```
[Device-portal-local-websvr-http] default-logon-page defaultfile.zip
```

Specify the HTTP listening port number as 80 for the portal Web service.

```
[Device–portal-local-websvr-http] tcp-port 80
[Device-portal-local-websvr-http] quit
```

4. Configure local Web authentication:

Create a local Web server named **user** for Web authentication and enter its view.

```
[Device] web-auth server user
```

Configure the redirection URL for the local Web server as **http://20.20.0.1:80/portal/**.

```
[Device-web-auth-server-user] url http://20.20.0.1:80/portal/
```

Specify the IP address of the local Web server as 20.20.0.1 (the IP address of Loopback 0) and the port number as 80.

```
[Device-web-auth-server-user] ip 20.20.0.1 port 80
[Device-web-auth-server-user] quit
```

Specify ISP domain **local** as the Web authentication domain.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] web-auth domain local
```

Enable Web authentication that uses local Web server **user**.

```
[Device-GigabitEthernet1/0/1] web-auth enable apply server user
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Display online Web authentication user information after user **localuser** passes Web authentication.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: localuser
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 100
  Authorization VLAN: N/A
```

```
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization microsegment ID: N/A
```

Example: Configuring local Web authentication by using the AAA remote authentication method

Network configuration

As shown in Figure 6, the host is directly connected to the device through GigabitEthernet 1/0/1.

Configure local Web authentication on GigabitEthernet 1/0/1, and use a remote RADIUS server to perform authentication, authorization, and accounting for the local Web authentication users.

Configure a local Web server on the device that uses the IP address of Loopback 0 and port 80 for Web authentication. Configure the device to use HTTP to transfer the authentication data.

Figure 6 Network diagram

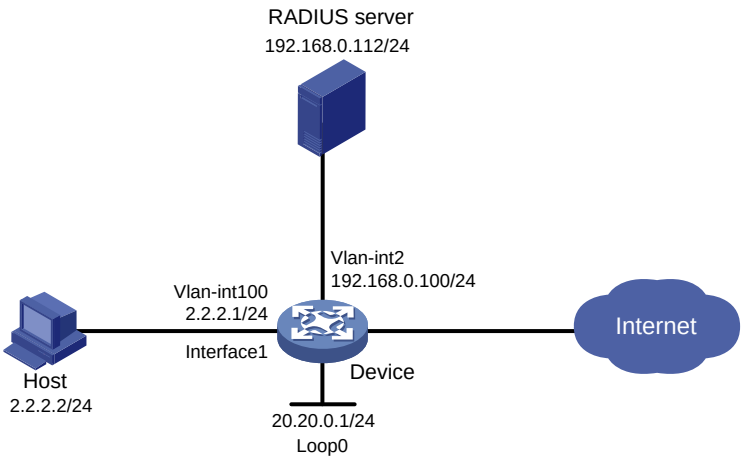

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Prerequisites

- Configure the RADIUS server properly to provide authentication, authorization, and accounting functions for users. In this example, the username is configured as **user1** on the RADIUS server.
- Create VLANs, assign IP addresses to the VLAN interfaces, and assign interfaces to the VLANs. Make sure the host, the RADIUS server, and the device can reach each other.

Procedure

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1**.

```
<Device> system-view
[Device] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Device-radius-rs1] primary authentication 192.168.0.112
```

```
[Device-radius-rs1] primary accounting 192.168.0.112
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
```

Exclude the ISP domain name from the username sent to the RADIUS server.

```
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
```

2. Configure an authentication domain:

Create an ISP domain named **dm1**.

```
[Device] domain dm1
```

Configure AAA methods for the ISP domain

```
[Device-isp-dm1] authentication lan-access radius-scheme rs1
[Device-isp-dm1] authorization lan-access radius-scheme rs1
[Device-isp-dm1] accounting lan-access radius-scheme rs1
[Device-isp-dm1] quit
```

3. Configure a local portal Web service:

Create an HTTP-based local portal Web service.

```
[Device] portal local-web-server http
```

Specify the file **defaultfile.zip** as the default authentication page file for the local portal Web service. (Make sure the authentication page file already exists in the root directory of the storage medium on the device.)

```
[Device-portal-local-websvr-http] default-logon-page defaultfile.zip
```

Specify 80 as the port number listened by the local portal Web service.

```
[Device–portal-local-websvr-http] tcp-port 80
[Device-portal-local-websvr-http] quit
```

4. Configure local Web authentication:

Create a local Web server named **user** for Web authentication and enter its view.

```
[Device] web-auth server user
```

Specify **http://20.20.0.1:80/portal/** as the redirection URL for the local Web server.

```
[Device-web-auth-server-user] url http://20.20.0.1:80/portal/
```

Specify the IP address of the local Web server as 20.20.0.1 (the IP address of Loopback 0) and the port number as 80.

```
[Device-web-auth-server-user] ip 20.20.0.1 port 80
[Device-web-auth-server-user] quit
```

Specify domain **dml** as the Web authentication domain.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] web-auth domain dm1
```

Enable Web authentication that uses local Web server **user**.

```
[Device-GigabitEthernet1/0/1] web-auth enable apply server user
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Display Web authentication user information after user **user1** passes Web authentication.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: user1
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
```

```
Initial VLAN: 100
Authorization VLAN: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization microsegment ID: N/A
```

Example: Configuring remote Web authentication by using the AAA local authentication method

Network configuration

As shown in Figure 7, the host is directly connected to the device through GigabitEthernet 1/0/1.

Configure remote Web authentication on GigabitEthernet 1/0/1, and configure the device to perform local authentication and authorization for the remote Web authentication users.

The remote Web server pushes Web authentication pages to users.

Figure 7 Network diagram

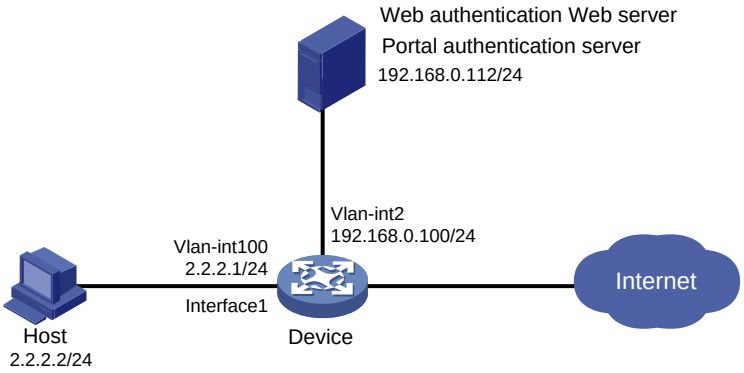

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Prerequisites

- Configure the portal authentication server properly to provide normal portal functions for users.
- Create VLANs, assign IP addresses to the VLAN interfaces, and assign interfaces to the VLANs. Make sure the host, the RADIUS server, and the device can reach each other.

Procedure

1. Configure a local user:

   # Create a local network access user named **localuser**.

   ```
   <Device>system-view
   [Device] local-user localuser class network
   ```

   # Set the password for user **localuser.**

   ```
   [Device-luser-network-localuser] password simple 123456TESTplat&!
   ```

   # Authorize the user to use LAN access services.

   ```
   [Device-luser-network-localuser] service-type lan-access
   [Device-luser-network-localuser] quit
   ```

2. Configure an ISP domain:

   # Create an ISP domain named **local**.

   ```
   [Device] domain local
   ```

   # Configure the ISP domain to perform local authentication, authorization, and accounting for LAN access users.

   ```
   [Device-isp-local] authentication lan-access local
   [Device-isp-local] authorization lan-access local
   [Device-isp-local] accounting lan-access local
   [Device-isp-local] quit
   ```

3. Configure the portal authentication server:

   ```
   [Device] portal server newpt
   [Device-portal-server-newpt] ip 192.168.0.112 key simple portal
   [Device-portal-server-newpt] port 50100
   [Device-portal-server-newpt] quit
   ```

4. Configure remote Web authentication:

   # Create a remote Web server named **user** for Web authentication and enter its view.

   ```
   [Device] web-auth remote server user
   ```

   # Configure the redirection URL of the remote Web server as **https://192.168.0.112:8080/portal/**.

   ```
   [Device-web-auth-remote-server-user] url https://192.168.0.112:8080/portal/
   ```

   # Configure the IP address of the remote Web server as 192.168.0.112.

   ```
   [Device-web-auth-remote-server-user] ip 192.168.0.112
   [Device-web-auth-remote-server-user] quit
   ```

   # Specify an authentication domain for Web authentication users.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] web-auth domain local
   ```

   # Enable Web authentication that uses remote Web server **user**.

   ```
   [Device-GigabitEthernet1/0/1] web-auth enable apply server user
   [Device-GigabitEthernet1/0/1] quit
   ```

5. Configure the device to obtain user information from ARP entries.

   ```
   [Device] portal access-info trust arp
   ```

Verifying the configuration

Display Web authentication user information after user **user1** passes Web authentication.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: user1
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 100
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
  Authorization user profile: N/A
  Authorization microsegment ID: N/A
```

Example: Configuring remote Web authentication by using the AAA remote authentication method

Network configuration

As shown in Figure 8, the host is directly connected to the device through GigabitEthernet 1/0/1.

Configure remote Web authentication on GigabitEthernet 1/0/1, and use a remote RADIUS server to perform authentication, authorization, and accounting for the remote Web authentication users.

The remote Web server pushes Web authentication pages to users.

Figure 8 Network diagram

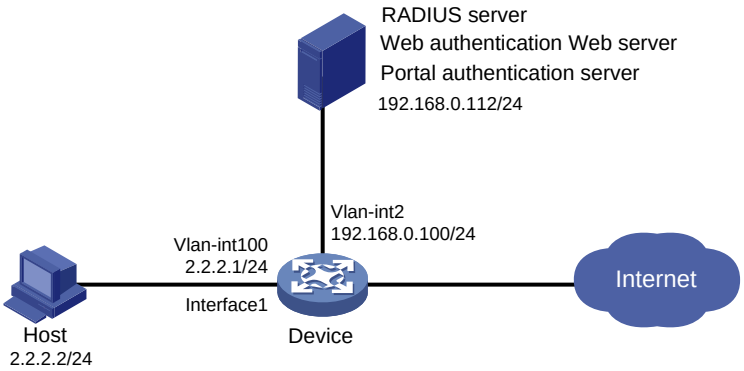

Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Prerequisites

- Configure the RADIUS server properly to provide authentication, authorization, and accounting functions for users. In this example, the username is configured as **user1** on the RADIUS server.
- Configure the portal authentication server properly to provide normal portal functions for users.
- Create VLANs, assign IP addresses to the VLAN interfaces, and assign interfaces to the VLANs. Make sure the host, the RADIUS server, and the device can reach each other.

Procedure

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1**.

```
<Device> system-view
[Device] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Device-radius-rs1] primary authentication 192.168.0.112
[Device-radius-rs1] primary accounting 192.168.0.112
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
```

Exclude the ISP domain name from the username sent to the RADIUS server.

```
[Device-radius-rs1] user-name-format without-domain
```

```
[Device-radius-rs1] quit
```

2. Configure an authentication domain:

   # Create an ISP domain named **dm1**.

   ```
   [Device] domain dm1
   ```

   # Configure AAA methods for the ISP domain

   ```
   [Device-isp-dm1] authentication lan-access radius-scheme rs1
   [Device-isp-dm1] authorization lan-access radius-scheme rs1
   [Device-isp-dm1] accounting lan-access radius-scheme rs1
   [Device-isp-dm1] quit
   ```

3. Configure the portal authentication server:

   ```
   [Device] portal server newpt
   [Device-portal-server-newpt] ip 192.168.0.112 key simple portal
   [Device-portal-server-newpt] port 50100
   [Device-portal-server-newpt] quit
   ```

4. Configure remote Web authentication:

   # Create a remote Web server named **user** for Web authentication and enter its view.

   ```
   [Device] web-auth remote server user
   ```

   # Configure the redirection URL of the remote Web server as **https://192.168.0.112:8080/portal/**.

   ```
   [Device-web-auth-remote-server-user] url https://192.168.0.112:8080/portal/
   ```

   # Configure the IP address of the remote Web server as 192.168.0.112.

   ```
   [Device-web-auth-remote-server-user] ip 192.168.0.112
   [Device-web-auth-remote-server-user] quit
   ```

   # Specify an authentication domain for Web authentication users.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] web-auth domain dm1
   ```

   # Enable Web authentication that uses remote Web server **user**.

   ```
   [Device-GigabitEthernet1/0/1] web-auth enable apply server user
   [Device-GigabitEthernet1/0/1] quit
   ```

5. Configure the device to obtain user information from ARP entries.

   ```
   [Device] portal access-info trust arp
   ```

Verifying the configuration

Display Web authentication user information after user **user1** passes Web authentication.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: user1
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 100
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
  Authorization user profile: N/A
  Authorization microsegment ID: N/A
```

Troubleshooting Web authentication

Failure to come online (local authentication interface using the default ISP domain

Symptom

No authentication domain is specified for the local authentication interface. A user fails to pass Web authentication to come online.

Analysis

If no Web authentication domain is specified, the system default ISP domain (domain **system**) is used for Web authentication. The system default domain uses the local authentication method by default. Using these default domain settings, the local authentication should have operated correctly.

The local authentication fails might because that the authentication method of the system default domain is changed or the system default domain is changed.

Solution

To resolve the problem, perform the following tasks:

1. Use the **`display domain`** command to identify whether the AAA methods for Web users in the system default domain are local.
2. If the AAA methods for Web users in the system default domain are not local, reconfigure the AAA methods as local.

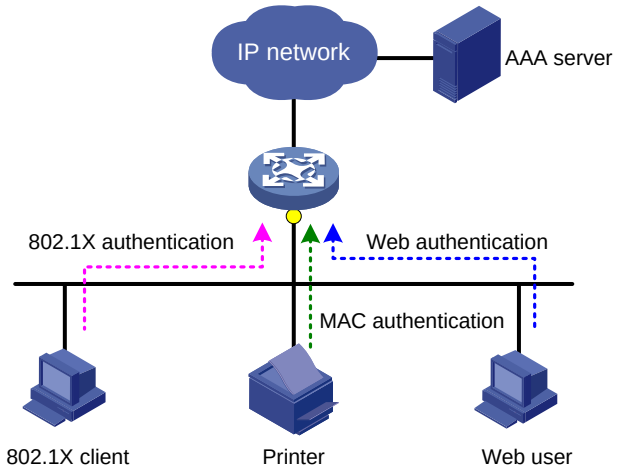
Configuring triple authentication



About triple authentication

Triple authentication enables an access port to perform Web, MAC, and 802.1X authentication. A terminal can access the network if it passes one type of authentication. For more information about 802.1X authentication, MAC authentication, and Web authentication, see "Configuring 802.1X authentication", "Configuring MAC authentication", and "Configuring Web authentication."

Typical network of triple authentication

Triple authentication is suitable for a LAN that comprises terminals that require different authentication services, as shown in Figure 1. The triple authentication-enabled access port can perform MAC authentication for the printer, 802.1X authentication for the PC installed with the 802.1X client, and Web authentication for the Web user.

Figure 1 Triple authentication network diagram

Triple authentication mechanism

The three types of authentication are triggered by different packets:

- The access port performs MAC authentication for a terminal when it receives an ARP or DHCP broadcast packet from the terminal for the first time. If the terminal passes MAC authentication, the terminal can access the network. If the MAC authentication fails, the access port performs 802.1X or Web authentication.
- The access port performs 802.1X authentication when it receives an EAP packet from an 802.1X client or a third-party client. If the unicast trigger feature of 802.1X is enabled on the access port, any packet from the client can trigger an 802.1X authentication.
- The access port performs Web authentication when it receives an HTTP packet from a terminal.

If a terminal triggers different types of authentication, the authentications are processed at the same time. The failure of one type of authentication does not affect the others. When a terminal passes one type of authentication, the other types of authentication are processed as follows:

- If the terminal first passes MAC authentication, Web authentication is terminated immediately, but 802.1X authentication will proceed. If the terminal also passes 802.1X authentication, the 802.1X authentication information will overwrite the MAC authentication information for the

terminal. If the terminal fails 802.1X authentication, the user stays online as a MAC authentication user, and only 802.1X authentication can be triggered again.

- If the terminal first passes 802.1X or Web authentication, the other types of authentication are terminated immediately and cannot be triggered again.

Triple authentication support for VLAN assignment

Authorization VLAN

After a user passes authentication, the authentication server assigns an authorization VLAN to the access port for the user. The user can then access the network resources in the authorized VLAN.

Authentication failure VLAN

The access port adds a user to an authentication failure VLAN configured on the port after the user fails authentication.

- For an 802.1X authentication user—Adds the user to the Auth-Fail VLAN configured for 802.1X authentication.
- For a Web authentication user—Adds the user to the Auth-Fail VLAN configured for Web authentication.
- For a MAC authentication user—Adds the user to the guest VLAN configured for MAC authentication.

If a user in the MAC authentication guest VLAN fails 802.1X authentication, the user is moved to the 802.1X Auth-Fail VLAN.

Server-unreachable VLAN

If a user fails authentication due to the unreachable server, the access port adds the user to an server-unreachable VLAN.

- For an 802.1X authentication user—Adds the user to the critical VLAN configured for 802.1X authentication.
- For a Web authentication user—Adds the user to the Auth-Fail VLAN configured for Web authentication.
- For a MAC authentication user—Adds the user to the critical VLAN configured for MAC authentication.

The access port supports configuring all types of server-unreachable VLANs at the same time. A user is added to the server-unreachable VLAN as follows:

- If the user does not undergo 802.1X authentication, the user is added to the server-unreachable VLAN configured for the last authentication.
- If the user in the Web Auth-Fail VLAN or MAC authentication critical VLAN also fails 802.1X authentication, the user is added to the 802.1X authentication critical VLAN.

Triple authentication support for ACL authorization

After a user passes authentication, the authentication server assigns an authorization ACL to the access port for the user. The access port uses the ACL to filter traffic for the user.

To use ACL authorization, you must specify authorization ACLs on the authentication server and configure the ACLs on the access device. You can change the user's access authorization by changing the authorization ACL on the authentication server or changing rules of the authorization ACL on the access device.

Triple authentication support for online user detection

You can configure the following features to detect the online status of users:

- Enable online user detection for Web authentication users.
- Enable the online user handshake or periodic online user reauthentication feature for 802.1X users.
- Enable offline detection for MAC authentication users.

Restrictions and guidelines: Triple authentication

In triple authentication, 802.1X authentication must use the MAC-based access control method.

If Web authentication is enabled on a port, configure the subnets of the server-unreachable VLANs of the port as Web authentication-free subnets. This ensures that an authentication-failed user can access the server-unreachable VLAN.

Do not configure both Web authentication-free IPs and 802.1X free IPs. If you do so, only 802.1X free IPs take effect.

Web authentication cannot be configured in conjunction with the following settings:

- Guest VLAN, Auth-Fail VLAN, and critical VLAN of 802.1 X authentication.
- Guest VLAN and critical VLAN of MAC authentication.

Triple authentication tasks at a glance

Choose the following tasks as needed:

- Configure 802.1X authentication

  For more information, see "Configuring 802.1X."
- Configure MAC authentication

  For more information, see "Configuring MAC authentication."
- Configure Web authentication

  For more information, see "Configuring Web authentication."

In triple authentication, if the above three authentication methods are configured, use the **`port-security triple-auth-order mac-dot1x-web`** command to specify the authentication order as MAC authentication, 802.1X authentication, and Web authentication. For more information about the **`port-security triple-auth-order mac-dot1x-web`** command, see port security commands in *Security Command Reference*.

Triple authentication configuration examples

Example: Configuring basic triple authentication

Network configuration

As shown in Figure 2, the terminals are connected to the device to access the IP network. Configure triple authentication on the device's Layer 2 interface that connects to the terminals. A terminal passing one of the three authentication methods, 802.1X authentication, Web authentication, and MAC authentication, can access the IP network.

- Assign IP addresses on subnet 192.168.1.0/24 to the terminals.

- Use the remote RADIUS server to perform authentication, authorization, and accounting. Configure the device to send usernames carrying no ISP domain names to the RADIUS server.
- Configure the local Web authentication server on the device to use listening IP address 4.4.4.4. Configure the device to send a default authentication page to the Web user and forward authentication data by using HTTP.

Figure 2 Network diagram

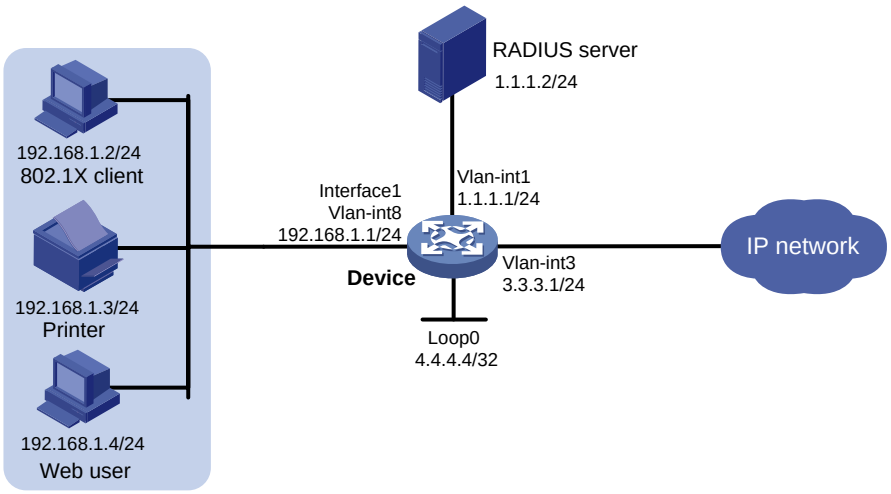


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Make sure that the terminals, the server, and the device can reach each other. (Details not shown.)
2. Configure the RADIUS server to provide normal authentication, authorization, and accounting for users. In this example, configure the following on the RADIUS server:
   - An 802.1X user with username **userdot**.
   - A Web authentication user with username **userpt**.
   - A MAC authentication user with a username and password both being the MAC address of the printer **f07d6870725f**.
3. Configure Web authentication:

   # Configure VLANs and IP addresses for the VLAN interfaces, and add ports to specific VLANs. (Details not shown.)

   # Create an HTTP-based local portal Web service, and specify file **defaultfile.zip** as the default authentication page file of the local portal Web service. (Make sure the authentication page file already exists in the root directory of the storage medium on the device.)

   ```
   <Device> system-view
   [Device] portal local-web-server http
   [Device-portal-local-websvr-http] default-logon-page defaultfile.zip
   [Device-portal-local-websvr-http] quit
   ```

   # Assign IP address 4.4.4.4 to Loopback 0.

   ```
   [Device] interface loopback 0
   [Device-LoopBack0] ip address 4.4.4.4 32
   [Device-LoopBack0] quit
   ```

Create a Web authentication server named **webserver** and enter its view.

```
[Device] web-auth server webserver
```

Configure the redirection URL for the Web authentication server as **https://4.4.4.4/portal/**.

```
[Device-web-auth-server-webserver] url https://4.4.4.4/portal/
```

Specify 4.4.4.4 as the IP address and 80 as the port number of the Web authentication server.

```
[Device-web-auth-server-webserver] ip 4.4.4.4 port 80
[Device-web-auth-server-webserver] quit
```

Enable Web authentication on GigabitEthernet 1/0/1 and specify Web authentication server **webserver** on the interface.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] web-auth enable apply server webserver
[Device–GigabitEthernet1/0/1] quit
```

4. Configure 802.1X authentication:

Enable 802.1X authentication globally.

```
[Device] dot1x
```

Enable 802.1X authentication (MAC-based access control required) on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] dot1x port-method macbased
[Device–GigabitEthernet1/0/1] dot1x
[Device–GigabitEthernet1/0/1] quit
```

5. Configure MAC authentication:

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Enable MAC authentication on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] mac-authentication
[Device–GigabitEthernet1/0/1] quit
```

6. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1**.

```
[Device] radius scheme rs1
```

Specify the primary authentication and accounting servers and keys.

```
[Device-radius-rs1] primary authentication 1.1.1.2
[Device-radius-rs1] primary accounting 1.1.1.2
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
```

Specify usernames sent to the RADIUS server to carry no domain names.

```
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
```

7. Configure an ISP domain:

Create an ISP domain named **triple**.

```
[Device] domain triple
```

Configure the domain to use RADIUS scheme **rs1** for authentication, authorization and accounting of LAN access users.

```
[Device-isp-triple] authentication lan-access radius-scheme rs1
[Device-isp-triple] authorization lan-access radius-scheme rs1
[Device-isp-triple] accounting lan-access radius-scheme rs1
```

```
[Device-isp-triple] quit
```

Configure domain **triple** as the default domain. If a username entered by a user includes no ISP domain name, the AAA method of the default domain is used.

```
[Device] domain default enable triple
```

Verifying the configuration

1. Verify that the Web user can pass Web authentication.

   # On the Web user terminal, use a Web browser to access an external network and then enter the correct username and password on the authentication page **https://4.4.4.4/portal/logon.html**. (Details not shown.)

   # Display information about online Web authentication users.

```
[Device] display web-auth user
  Total online web-auth users: 1
User Name: localuser
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 8
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
  Authorization user profile: N/A
```

2. Verify that the printer can pass MAC authentication.

   # Connect the printer to the network. (Details not shown.)

   # Display information about online MAC authentication users.

```
[Device] display mac-authentication connection
Total connections: 1
Slot ID: 1
User MAC address: f07d-6870-725f
Access interface: GigabitEthernet1/0/1
Username: f07d6870725f
User access state: Successful
Authentication domain: triple
Initial VLAN: 8
Authorization untagged VLAN: N/A
Authorization tagged VLAN: N/A
Authorization VSI: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: N/A
Online from: 2015/01/04 18:01:43
Online duration: 0h 0m 2s
```

3. Verify that the 802.1X client can pass 802.1X authentication.

   # On the 802.1X client, initiate 802.1X authentication and then enter the correct username and password. (Details not shown.)

   # Display information about online 802.1X users.

```
[Device] display dot1x connection
Total connections: 1
```

```
Slot ID: 1
User MAC address: 7446-a091-84fe
Access interface: GigabitEthernet1/0/1
Username: userdot
User access state: Successful
Authentication domain: triple
IPv4 address: 192.168.1.2
Authentication method: CHAP
Initial VLAN: 8
Authorization untagged VLAN: N/A
Authorization tagged VLAN list: N/A
Authorization VSI: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: N/A
Online from: 2015/01/04 18:13:01
Online duration: 0h 0m 14s
```

Example: Configuring triple authentication to support authorization VLAN and authentication failure VLAN

Network configuration

As shown in Figure 3, the terminals are connected to the device to access the IP network. Configure triple authentication on the device's Layer 2 interface connected to the terminals. A terminal passing one of the three authentication methods, 802.1X authentication, Web authentication, and MAC authentication, can access the IP network.

- The Web authentication terminal uses DHCP to get an IP address in 192.168.1.0/24 before authentication and in 3.3.3.0/24 after passing authentication. If the terminal fails authentication, it requests IP addresses in 2.2.2.0/24 through DHCP.

  You can use the access device or an attached device as the DHCP server. In this example, the access device (the device) provides the DHCP service.
- The 802.1X terminal uses DHCP to get an IP address in 192.168.1.0/24 before authentication and in 3.3.3.0/24 after passing authentication. If the terminal fails authentication, it requests IP addresses in 2.2.2.0/24 through DHCP.
- After passing authentication, the printer obtains IP address 3.3.3.111/24 that is bound with its MAC address through DHCP.
- Use the remote RADIUS server to perform authentication, authorization, and accounting. Configure the device to remove the ISP domain names from usernames sent to the RADIUS server.
- Configure the local Web authentication server on the device to use listening IP address 4.4.4.4. Configure the device to forward authentication data by using HTTP.
- Configure VLAN 3 as the authorization VLAN. Users passing authentication are added to this VLAN.
- Configure VLAN 2 as the authentication failure VLAN. Users failing authentication are added to this VLAN.

Figure 3 Network diagram

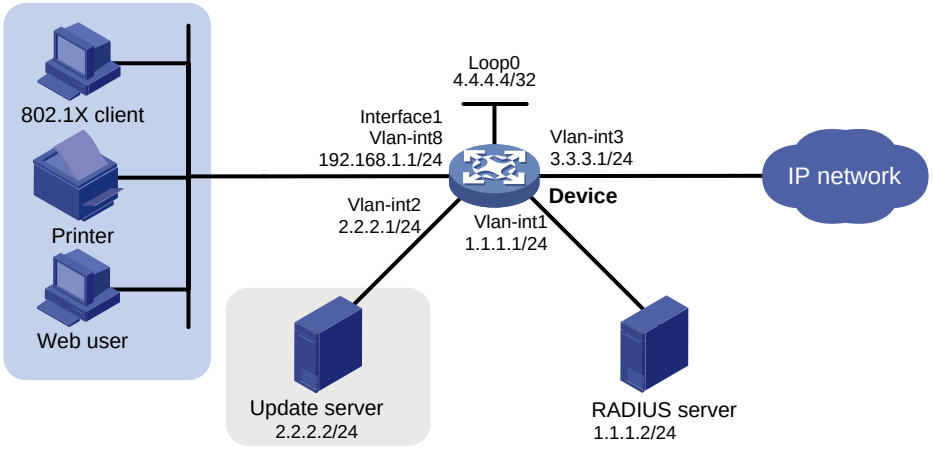

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Make sure the terminals, the servers, and the device can reach each other. (Details not shown.)
2. Configure the RADIUS server to provide normal authentication, authorization, and accounting for users. In this example, configure the following on the RADIUS server:
   - An 802.1X user with username **userdot**.
   - A Web authentication user with username **userpt**.
   - A MAC authentication user with a username and password both being the MAC address of the printer **f07d6870725f**.
   - An authorization VLAN (VLAN 3).
3. Configure the IP address of the update server as an authentication-free IP address.

   ```
   <Device> system-view
   [Device] web-auth free-ip 2.2.2.2 24
   ```
4. Configure DHCP:

   # Configure VLANs and IP addresses for the VLAN interfaces, and add ports to specific VLANs. (Details not shown.)

   # Enable DHCP.

   ```
   [Device] dhcp enable
   ```

   # Exclude the IP address of the update server from dynamic address assignment.

   ```
   [Device] dhcp server forbidden-ip 2.2.2.2
   ```

   # Configure DHCP address pool 1 to assign IP addresses and other configuration parameters to clients on subnet 192.168.1.0.

   ```
   [Device] dhcp server ip-pool 1
   [Device-dhcp-pool-1] network 192.168.1.0 mask 255.255.255.0
   [Device-dhcp-pool-1] expired day 0 hour 0 minute 1
   [Device-dhcp-pool-1] gateway-list 192.168.1.1
   [Device-dhcp-pool-1] quit
   ```

   # Configure DHCP address pool 2 to assign IP address and other configuration parameters to clients on subnet 2.2.2.0.

```
[Device] dhcp server ip-pool 2
[Device-dhcp-pool-2] network 2.2.2.0 mask 255.255.255.0
[Device-dhcp-pool-2] expired day 0 hour 0 minute 1
[Device-dhcp-pool-2] gateway-list 2.2.2.1
[Device-dhcp-pool-2] quit
```

Configure DHCP address pool 3 to assign IP address and other configuration parameters to clients on subnet 3.3.3.0.

```
[Device] dhcp server ip-pool 3
[Device-dhcp-pool-3] network 3.3.3.0 mask 255.255.255.0
[Device-dhcp-pool-3] expired day 0 hour 0 minute 1
[Device-dhcp-pool-3] gateway-list 3.3.3.1
[Device-dhcp-pool-3] quit
```

Configure DHCP address pool 4, and bind the printer's MAC address f07d-6870-725f to IP address 3.3.3.111/24 in this address pool.

```
[Device] dhcp server ip-pool 4
[Device-dhcp-pool-4] static-bind ip-address 3.3.3.111 mask 255.255.255.0
client-identifier f07d-6870-725f
[Device-dhcp-pool-4] quit
```

5. Configure Web authentication:

Create an HTTP-based local portal Web service, and specify file **defaultfile.zip** as the default authentication page file of the local portal Web service. (Make sure the authentication page file already exists in the root directory of the storage medium on the device.)

```
[Device] portal local-web-server http
[Device-portal-local-websvr-http] default-logon-page defaultfile.zip
[Device-portal-local-websvr-http] quit
```

Assign IP address 4.4.4.4 to Loopback 0.

```
[Device] interface loopback 0
[Device-LoopBack0] ip address 4.4.4.4 32
[Device-LoopBack0] quit
```

Create a Web authentication server named **webserver**.

```
[Device] web-auth server webserver
```

Configure the redirection URL of the Web authentication server as **https://4.4.4.4/portal/**.

```
[Device-web-auth-server-webserver] url https://4.4.4.4/portal/
```

Specify 4.4.4.4 as the IP address and 80 as the port number of the Web authentication server.

```
[Device-web-auth-server-webserver] ip 4.4.4.4 port 80
[Device-web-auth-server-webserver] quit
```

Configure the IP address of the update server as an authentication-free IP address.

```
[Device] web-auth free-ip 2.2.2.2 24
```

Enable Web authentication on GigabitEthernet 1/0/1 and specify VLAN 2 as the Auth-Fail VLAN.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] port link-type hybrid
[Device–GigabitEthernet1/0/1] mac-vlan enable
[Device–GigabitEthernet1/0/1] web-auth enable apply server webserver
[Device–GigabitEthernet1/0/1] web-auth auth-fail vlan 2
[Device–GigabitEthernet1/0/1] quit
```

6. Configure 802.1X authentication:

Enable 802.1X authentication globally.

```
[Device] dot1x
```

Enable 802.1X authentication (MAC-based access control required) on GigabitEthernet 1/0/1, and specify VLAN 2 as the Auth-Fail VLAN.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] dot1x port-method macbased
[Device–GigabitEthernet1/0/1] dot1x
[Device–GigabitEthernet1/0/1] dot1x auth-fail vlan 2
[Device–GigabitEthernet1/0/1] quit
```

7. Configure MAC authentication:

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Enable MAC authentication on GigabitEthernet 1/0/1, and specify VLAN 2 as the guest VLAN.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] mac-authentication
[Device–GigabitEthernet1/0/1] mac-authentication guest-vlan 2
[Device–GigabitEthernet1/0/1] quit
```

8. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1**.

```
[Device] radius scheme rs1
```

Specify the primary authentication and accounting servers and keys.

```
[Device-radius-rs1] primary authentication 1.1.1.2
[Device-radius-rs1] primary accounting 1.1.1.2
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
```

Specify usernames sent to the RADIUS server to carry no domain names.

```
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
```

9. Configure an ISP domain:

Create an ISP domain named **triple**.

```
[Device] domain triple
```

Configure the domain to use RADIUS scheme **rs1** for authentication, authorization and accounting of LAN access users.

```
[Device-isp-triple] authentication lan-access radius-scheme rs1
[Device-isp-triple] authorization lan-access radius-scheme rs1
[Device-isp-triple] accounting lan-access radius-scheme rs1
[Device-isp-triple] quit
```

Configure domain **triple** as the default domain. If a username entered by a user includes no ISP domain name, the AAA methods of the default domain is used.

```
[Device] domain default enable triple
```

Verifying the configuration

1. Verify that the Web user can pass Web authentication.

On the Web user terminal, use a Web browser to access an external network and then enter the correct username and password on the authentication page **https://4.4.4.4/portal/logon.html**. (Details not shown.)

Use the **display web-auth user** command to display information about online users.

```
[Device] display web-auth user
  Total online web-auth users: 1
```

```
User Name: userpt
  MAC address: 6805-ca17-4a0b
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 8
  Authorization VLAN: 3
  Authorization ACL ID: N/A
  Authorization user profile: N/A
```

2. Verify that the printer can pass MAC authentication.

Connect the printer to the network. (Details not shown.)

Display information about online MAC authentication users.

```
[Device] display mac-authentication connection
Total connections: 1
Slot ID: 1
User MAC address: f07d-6870-725f
Access interface: GigabitEthernet1/0/1
Username: f07d6870725f
User access state: Successful
Authentication domain: triple
Initial VLAN: 8
Authorization untagged VLAN: 3
Authorization tagged VLAN: N/A
Authorization VSI: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: N/A
Online from: 2015/01/04 18:01:43
Online duration: 0h 0m 2s
```

3. Verify that the 802.1X user can pass 802.1X authentication.

On the 802.1X client, initiate 802.1X authentication and enter the correct username and password. (Details not shown.)

Display information about online 802.1X users.

```
[Device] display dot1x connection
Total connections: 1
Slot ID: 1
User MAC address: 7446-a091-84fe
Access interface: GigabitEthernet1/0/1
Username: userdot
User access state: Successful
Authentication domain: triple
IPv4 address: 3.3.3.3
Authentication method: CHAP
Initial VLAN: 8
Authorization untagged VLAN: 3
Authorization tagged VLAN list: N/A
```

```
Authorization VSI: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: N/A
Online from: 2015/01/04 18:13:01
Online duration: 0h 0m 14s
```

4. Verify that users that pass authentication have been assigned authorization VLANs.

Display MAC-VLAN entries of online users.

```
[Device] display mac-vlan all
  The following MAC VLAN addresses exist:
  S:Static  D:Dynamic
  MAC ADDR         MASK             VLAN ID   PRIO   STATE
  ------------------------------------------------------------
  6805-ca17-4a0b   ffff-ffff-ffff   3         0      D
  f07d-6870-725f   ffff-ffff-ffff   3         0      D
  7446-a091-84fe   ffff-ffff-ffff   3         0      D
  Total MAC VLAN address count:3
```

5. Verify that online users have been assigned IP addresses.

```
[Device] display dhcp server ip-in-use
IP address       Client-identifier/    Lease expiration          Type
                  Hardware address
 3.3.3.111        01f0-7d68-7072-5f     Jan  4 18:14:17 2015      Auto:(C)
 3.3.3.2          0168-05ca-174a-0b     Jan  4 18:15:01 2015      Auto:(C)
 3.3.3.3          0174-46a0-9184-fe     Jan  4 18:15:03 2015      Auto:(C)
```

6. When a terminal fails authentication, it is added to VLAN 2. You can use the previous display commands to display the MAC-VLAN entry and IP address of the terminal. (Details not shown.)

Configuring port security

About port security

Port security not only provides port security modes to enhance network access security, but also provides MAC-based network access control for 802.1X, MAC authentication, Web authentication, and static users.

Major port security functions

Port security provides multiple security modes, intrusion detection and port security protection, and unified management of access authentication.

Multiple port security modes

Port security provides different security modes to control MAC address learning on ports and define combinations of authentication methods. It enables the device to learn legitimate source MAC addresses and simplifies the procedure to configure basic port authentication for desired network management.

Intrusion detection and port security protection

Typically, you use the intrusion detection and port security protection features in conjunction with port security modes to enhance security.

NTK

The need to know (NTK) feature prevents traffic interception by checking the destination MAC address in the outbound frames. The feature ensures that frames are sent only to the following hosts:

- Hosts that have passed authentication.
- Hosts whose MAC addresses have been learned or configured on the access device.

The NTK feature supports the following modes:

- **ntk-withbroadcasts**—Forwards only broadcast and unicast frames with a known destination MAC address.
- **ntk-withmulticasts**—Forwards only broadcast, multicast, and unicast frames with a known destination MAC address.
- **ntkauto**—Forwards only broadcast, multicast, and unicast frames with a known destination MAC address, and only when the port has online users.
- **ntkonly**—Forwards only unicast frames with a known destination MAC address.

Intrusion protection

The intrusion protection feature checks the source MAC address in inbound frames for illegal frames, and takes a predefined action on each detected illegal frame. The action can be disabling the port temporarily, disabling the port permanently, or blocking frames from the illegal MAC address for a period set by the MAC block timer.

A frame is illegal if its source MAC address cannot be learned in a port security mode or it is from a client that has failed 802.1X or MAC authentication.

Intrusion protection takes one of the following actions on a port in response to illegal frames:

- **blockmac**—Adds the source MAC addresses of illegal frames to the blocked MAC address list, and then discards frames sourced from blocked MAC addresses for a period set by the block timer. A blocked MAC address will be unblocked when the block timer expires.

- **disableport**—Disables the port until you bring it up manually.
- **disableport-temporarily**—Disables the port for a period of time. The period can be configured with the **`port-security timer disableport`** command.

Unified management of access authentication on ports

Port security enables centralized configuration and management of authentication methods (802.1X, MAC authentication, Web authentication, and static users) on ports, as well as centralized management of access users.

Port security modes

Port security supports the following categories of security modes:

- **MAC learning control**—Includes two modes: autoLearn and secure. MAC address learning is permitted on a port in autoLearn mode and disabled in secure mode.
- **Authentication**—Security modes in this category implement MAC authentication, 802.1X authentication, or a combination of these two authentication methods.

Controlling MAC address learning

- autoLearn.

  A port in this mode can learn MAC addresses. The automatically learned MAC addresses are not added to the MAC address table as dynamic MAC address. Instead, these MAC addresses are added to the secure MAC address table as secure MAC addresses. You can also configure secure MAC addresses by using the **`port-security mac-address security`** command.

  A port in autoLearn mode allows frames sourced from the following MAC addresses to pass:

  - Secure MAC addresses.
  - MAC addresses configured by using the **`mac-address dynamic`** and **`mac-address static`** commands.

  When the number of secure MAC addresses reaches the upper limit, the port transitions to secure mode.

- secure.

  MAC address learning is disabled on a port in secure mode. You configure MAC addresses by using the **`mac-address static`** and **`mac-address dynamic`** commands. For more information about configuring MAC address table entries, see *Layer 2—LAN Switching Configuration Guide*.

  A port in secure mode allows only frames sourced from the following MAC addresses to pass:

  - Secure MAC addresses.
  - MAC addresses configured by using the **`mac-address dynamic`** and **`mac-address static`** commands.

Performing authentication

For the ease of memory, use the following conventions to interprete the names of port security modes for authentication:

- **userLogin** specifies 802.1X authentication and port-based access control. **userLogin** with **Secure** specifies 802.1X authentication and MAC-based access control. **Ext** indicates allowing multiple 802.1X users to be authenticated and serviced at the same time. A security mode without **Ext** allows only one user to pass 802.1X authentication.
- **macAddress** specifies MAC authentication.
- **Else** specifies that the authentication method before **Else** is applied first. If the authentication fails, whether to turn to the authentication method following **Else** depends on the protocol type of the authentication request.

- **Or** specifies that the authentication method following **Or** is applied first. If the authentication fails, the authentication method before **Or** is applied.
- **And** indicates that the authentication method before **And** is applied first. After the authentication succeeds, the system turns to the authentication method that follows **And** upon receiving the request of the authentication method.

Performing 802.1X authentication

- userLogin.

  A port in this mode performs 802.1X authentication and implements port-based access control. The port can service multiple 802.1X users. Once an 802.1X user passes authentication on the port, any subsequent 802.1X users can access the network through the port without authentication.

- userLoginMab

  Perform port-based 802.1X MAC bypass authentication for users. If the device does not receive an EAP message from a user on a port in userLoginMab mode, the device authenticates the user by using the MAC address of the client as the username. After a successful authentication, the user will come online as an 802.1X user. On a port in this mode, after an 802.1X user passes authentication, the subsequent users can access the network without authentication.

- userLoginSecure.

  A port in this mode performs 802.1X authentication and implements MAC-based access control. The port services only one user passing 802.1X authentication.

- userLoginSecureExt.

  This mode is similar to the userLoginSecure mode except that this mode supports multiple online 802.1X users.

- userLoginWithOUI.

  This mode is similar to the userLoginSecure mode. The difference is that a port in this mode also permits frames from one user whose MAC address contains a specific OUI.

  In this mode, the port performs OUI check at first. If the OUI check fails, the port performs 802.1X authentication. The port permits frames that pass OUI check or 802.1X authentication.

NOTE:

An OUI is a 24-bit number that uniquely identifies a vendor, manufacturer, or organization. In MAC addresses, the first three octets are the OUI.

Performing MAC authentication

macAddressWithRadius: A port in this mode performs MAC authentication, and services multiple users.

Performing a combination of MAC authentication and 802.1X authentication

- macAddressOrUserLoginSecure.

  This mode is the combination of the macAddressWithRadius and userLoginSecure modes. The mode allows one 802.1X authentication user and multiple MAC authentication users to log in.

  In this mode, the port performs 802.1X authentication first. By default, if 802.1X authentication fails, MAC authentication is performed.

  However, the port in this mode processes authentication differently when the following conditions exist:

  - The port is enabled with parallel processing of MAC authentication and 802.1X authentication.
  - The port is enabled with the 802.1X unicast trigger.
  - The port receives a packet from an unknown MAC address.

Under such conditions, the port sends a unicast EAP-Request/Identity packet to the MAC address to initiate 802.1X authentication. After that, the port immediately processes MAC authentication without waiting for the 802.1X authentication result.

- macAddressOrUserLoginSecureExt.

  This mode is similar to the macAddressOrUserLoginSecure mode, except that this mode supports multiple 802.1X and MAC authentication users.

- macAddressElseUserLoginSecure.

  This mode is the combination of the macAddressWithRadius and userLoginSecure modes, with MAC authentication having a higher priority as the **Else** keyword implies. The mode allows one 802.1X authentication user and multiple MAC authentication users to log in.

  In this mode, the port performs MAC authentication upon receiving non-802.1X frames. Upon receiving 802.1X frames, the port performs MAC authentication and then, if the authentication fails, 802.1X authentication.

- macAddressElseUserLoginSecureExt.

  This mode is similar to the macAddressElseUserLoginSecure mode except that this mode supports multiple 802.1X and MAC authentication users as the **Ext** keyword implies.

- macAddressAndUserLoginSecureExt.

  In this mode, a user must pass both MAC authentication and 802.1X authentication to access the authorized network resources.

  The device uses the following process to handle an access user on a port operating in this mode:

  a. Performs MAC authentication for the user.

  b. Marks the user as a temporary MAC authentication user when the user passes MAC authentication. A temporary MAC authentication user can access only resources in the 802.1X guest VLAN or VSI.

  c. After receiving 802.1X protocol packets from the user on the port, the device performs 802.1X authentication for the user.

  d. After the user passes 802.1X authentication on the port, the device removes the temporary MAC authentication user entry. Then, the user comes online as an 802.1X user.

- macAddressAndUserLoginSecureExt.

  In this mode, a user must pass both MAC authentication and 802.1X authentication to access the authorized network resources.

  The device uses the following process to handle an access user on a port operating in this mode:

  a. Performs MAC authentication for the user.

  b. Marks the user as a temporary MAC authentication user when the user passes MAC authentication. A temporary MAC authentication user can access only resources in the 802.1X guest VLAN.

  c. After receiving 802.1X protocol packets from the user on the port, the device performs 802.1X authentication for the user.

  d. After the user passes 802.1X authentication on the port, the device removes the temporary MAC authentication user entry. Then, the user comes online as an 802.1X user.

- macAddressAndUserLoginSecureExt.

  In this mode, a user must pass both MAC authentication and 802.1X authentication to access the authorized network resources.

  The device uses the following process to handle an access user on a port operating in this mode:

  a. Performs MAC authentication for the user.

b. Marks the user as a temporary MAC authentication user when the user passes MAC authentication. A temporary MAC authentication user can access only resources in the 802.1X guest VLAN or guest VSI.

c. After receiving 802.1X protocol packets from the user on the port, the device performs 802.1X authentication for the user.

d. After the user passes 802.1X authentication on the port, the device removes the temporary MAC authentication user entry. Then, the user comes online as an 802.1X user.

Workflow in a port security mode

Upon receiving a frame, the port in a security mode searches the MAC address table for the source MAC address.

- If a match is found, the port forwards the frame.
- If no match is found, the port learns the MAC address or performs authentication, depending on the security mode.
  - If MAC address learning or user authentication succeeds, the device adds the MAC address to the MAC address table and forwards the frame.
  - If MAC address learning or user authentication fails, the device determines that the frame is illegal. It then takes the predefined NTK or intrusion protection action on the port or sends SNMP notifications.

Outgoing frames are not restricted by port security's NTK action unless they trigger the NTK feature.

Table 1 describes the port security modes and the security features.

Table 1 Port security modes

Purpose	Security mode		Features that can be triggered
Turning off the port security feature	noRestrictions (the default mode) In this mode, port security is disabled on the port and access to the port is not restricted.		N/A
Controlling MAC address learning	autoLearn		NTK/intrusion protection
	secure		
Performing authentication	userLogin		NTK (**ntkauto** mode)
	userLoginMab		
	userLoginSecure		NTK/intrusion protection
	userLoginSecureExt		
	userLoginWithOUI		
Performing authentication	macAddressWithRadius		NTK/intrusion protection
Performing authentication	Or	macAddressOrUserLoginSecure	NTK/intrusion protection
		macAddressOrUserLoginSecureExt	
	Else	macAddressElseUserLoginSecure	
		macAddressElseUserLoginSecureExt	
	And	macAddressAndUserLoginSecureExt	

The mode names are illustrated as follows:

- **userLogin** specifies 802.1X authentication and port-based access control. **userLogin** with **Secure** specifies 802.1X authentication and MAC-based access control. **Ext** indicates allowing

multiple 802.1X users to be authenticated and serviced at the same time. A security mode without **Ext** allows only one user to pass 802.1X authentication.

- **macAddress** specifies MAC authentication.
- **Else** specifies that the authentication method before **Else** is applied first. If the authentication fails, whether to turn to the authentication method following **Else** depends on the protocol type of the authentication request.
- **Or** specifies that the authentication method following **Or** is applied first. If the authentication fails, the authentication method before **Or** is applied.
- **And** indicates that the authentication method before **And** is applied first. After the authentication succeeds, the system turns to the authentication method that follows **And** upon receiving the request of the authentication method.

Secure MAC addresses

When port security is enabled, a port in a port security mode for MAC learning control permits only packets from the following types of MAC addresses to pass through:

- The secure MAC addresses on the port.
- The MAC addresses manually configured by using the **`mac-address dynamic`** command or the **`mac-address static`** command.

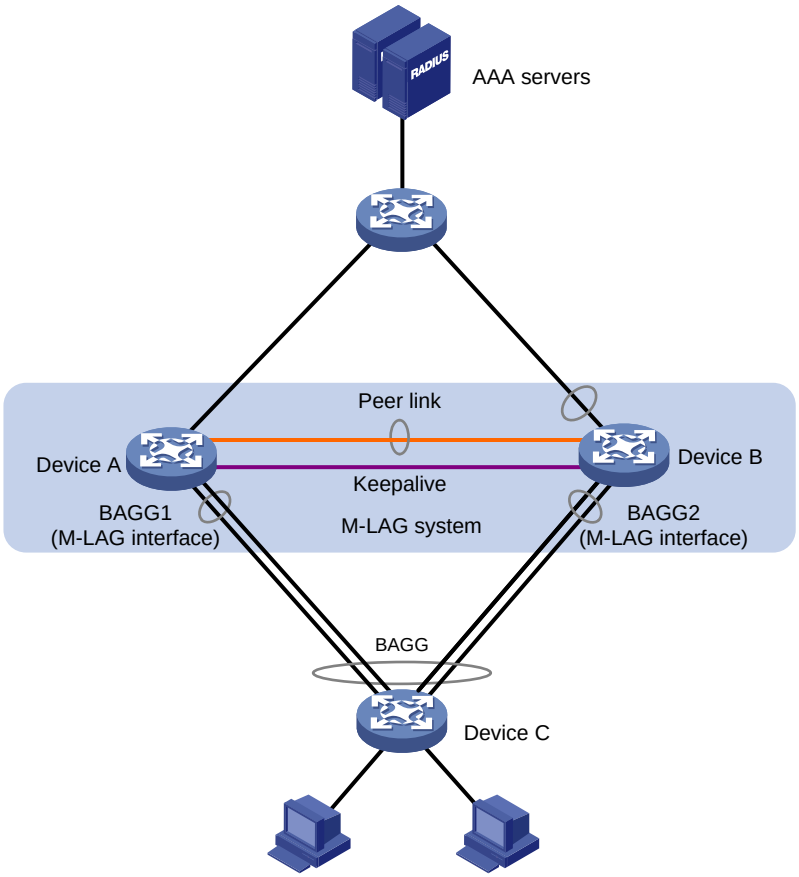
Secure MAC addresses include static, sticky, and dynamic secure MAC addresses, as shown in Table 2.

Table 2 Comparison of static, sticky, and dynamic secure MAC addresses

Type	Address sources	Can be saved and survive a device reboot?	Aging mechanism
Static	Manually added (by using the **`port-security mac-address security`** command without the **`sticky`** keyword).	Yes.	Not available. The static secure MAC addresses never age out unless you perform any of the following tasks: • Manually remove these MAC addresses. • Change the port security mode. • Disable the port security feature.
Sticky	• Manually added (by using the **`port-security mac-address security`** command with the **`sticky`** keyword). • Converted from dynamic secure MAC addresses. • Automatically learned when the dynamic secure MAC feature is disabled.	Yes. The secure MAC aging timer restarts at a reboot.	By default, sticky MAC addresses do not age out. However, you can configure an aging timer or use the aging timer together with the inactivity aging feature to remove old sticky MAC addresses. • If only the aging timer is configured, the aging timer counts up regardless of whether traffic data has been sent from the sticky MAC addresses. • If both the aging timer and the inactivity aging feature are configured, the aging timer restarts once traffic data is detected from the sticky MAC addresses.
Dynamic	• Converted from sticky MAC	No. All dynamic secure	Same as sticky MAC addresses.

Type	Address sources	Can be saved and survive a device reboot?	Aging mechanism
	addresses. • Automatically learned after the dynamic secure MAC feature is enabled.	MAC addresses are lost at reboot.	

Authentication load sharing modes in M-LAG environments



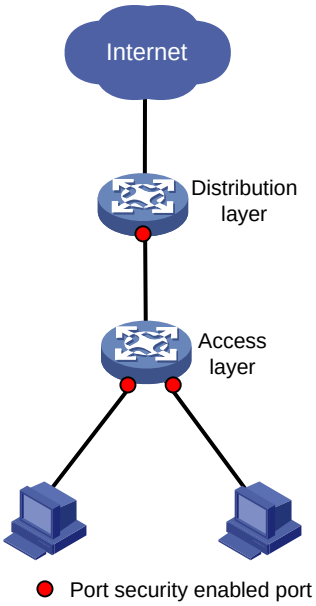
As shown in Figure 1, use M-LAG to configure Device A and Device B into an M-LAG system for load sharing and node redundancy. When one of the devices fails, traffic is switched to the other device to ensure service continuity.

For users attached to the M-LAG interfaces on an M-LAG system, port security provides the following authentication load sharing modes:

- **Centralized mode**—In this mode, the primary M-LAG member device processes authentication services for all users attached to any M-LAG interfaces in the system.
- **Distributed modes**—In a distributed mode, both M-LAG member devices provide authentication services for users attached to the M-LAG interfaces. Port security provides the following distributed authentication processing modes:
  - **Distributed local mode**—Each M-LAG member device processes authentication for users attached to their local M-LAG interfaces.
  - **Distributed even-/odd-MAC mode**—In this mode, one M-LAG member device processes authentication for packets with an even source MAC address and the other M-LAG member device processes authentication for packets with an odd source MAC address. In this mode, you must configure one M-LAG member device to process authentication for even source MAC addresses and configure the other M-LAG member device to process authentication for odd source MAC addresses.

One M-LAG member device automatically synchronizes user data to the other M-LAG member device upon each successful user authentication. This ensures that when one M-LAG member device fails, the other member device can take over to process authentication services for all users.

Figure 1 M-LAG network diagram



Port security application scenarios

Port security is typically used in the scenarios shown in Figure 2.

- Used on access devices to prevent fake users from launching attacks through ports other than those used by legitimate users.
  - If the access location of users is fixed but the link is unreliable, enable port security to convert their MAC addresses to sticky MAC addresses. This ensures that their MAC address bindings can be saved to the configuration file to persist throu gh device reboot or port state change between up and down.
  - If there are only a few users and their access location is fixed, manually configure their MAC addresses as static secure MAC addresses, which never age out.
  - If users frequently move between ports, configure port security to convert their MAC addresses to dynamic secure MAC addresses. This action ensures prompt removal of port and MAC bindings for inactive users, preventing unnecessary use of port and MAC binding resources. It also eliminates MAC entry conflicts to ensure that users can move between ports.
- Used on distribution devices to control the number of access users, preventing network congestion caused by excessive network accesses.

Figure 2 Port security application scenarios

Restrictions and guidelines: Port security configuration

This feature applies to networks, such as a WLAN, that require different authentication methods for different users on a port.

As a best practice, use the 802.1X authentication or MAC authentication feature rather than port security for scenarios that require only 802.1X authentication or MAC authentication. For more information about 802.1X and MAC authentication, see "Configuring 802.1X" and "Configuring MAC authentication."

The **`secure`** and **`userlogin-withoui`** port security modes are not supported on Layer 2 aggregate interfaces. Other port security settings are supported on both Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces.

After a Layer 2 Ethernet interface is added to an aggregation group, port security settings on the interface do not take effect.

Do not delete a Layer 2 aggregate interface if the interface has online 802.1X or MAC authentication users.

When RADIUS DAS is enabled, an M-LAG system does not support the following operations:

- Shuts down or reboots the access ports for 802.1X, Web authentication, MAC authentication users by sending CoA messages.
- Reauthenticates these users by sending CoA messages.

For more information about RADIUS DAS, see "Configuring AAA."

In an M-LAG scenario with load sharing in even-/odd-MAC mode, make sure the port security settings match on both devices except for the different processing modes. For other load sharing modes, keep all port security settings identical on both devices.

To ensure a successful HTTPS redirect for users in either of the following situations, make sure VLAN interfaces or VSI interfaces exist for the VLANs or VSIs that transport their packets:

- The users are assigned a redirect URL.

- EAD assistant is enabled.

Port security tasks at a glance

To configure port security, perform the following tasks:

1. Configuring basic features of port security
   - Enabling port security
   - Setting the port security mode
2. Configuring port security detection and protection

   You typically use port security detection and protection features in conjunction with port security modes for enhanced security.
   - (Optional.) Configuring NTK
   - (Optional.) Configuring intrusion protection
3. (Optional) Configuring secure MAC addresses and their control settings
   - (Optional.) Setting port security's limit on the number of secure MAC addresses on a port
   - (Optional.) Configuring secure MAC addresses
     - Adding a static secure MAC address
     - Adding a sticky MAC address
     - Converting sticky MAC addresses to dynamic secure MAC addresses
     - Configuring secure MAC address aging
4. (Optional.) Configuring extended features of port security

   The following features are applicable when port security is enabled or when 802.1X, MAC authentication or Web authentication is enabled.
   - Configuring an authentication load sharing mode for users attached to M-LAG interfaces

     Perform this task on an M-LAG system.
   - Configuring static users for port access authentication
     - Configuring a static user range for port access authentication
     - Enabling static user IP update
     - Setting the maximum number of concurrent static users allowed on a port
     - Specifying an ACL to match the MAC addresses of static users
   - Configuring port security authentication profile settings
     - Configuring a port security authentication profile
     - Configuring the port security authentication order (port security authentication profile view)
   - Configuring port security access policies
   - Ignoring authorization information from the server
   - Configuring MAC move
   - Enabling overwrite of local MAC entries with remote MAC entries for MAC addresses moved to a remote device
   - Enabling the authorization-fail-offline feature
   - Setting port security's limit on the number of MAC addresses for specific VLANs on a port
   - Enabling open authentication mode
   - Configuring free VLANs for port security
   - Applying a NAS-ID profile to port security

- Enabling the escape critical VSI feature for 802.1X and MAC authentication users
- Configuring single-access authentication
- Specifying a preauthentication domain for port security users on a port
- Specifying a domain for port security users redirected to an unavailable URL
- Setting port security timers
- Configuring the maximum number of reauthentication attempts for users in the preauthentication domain or Auth-Fail domain
- Enabling immediate reauthentication for users in the preauthentication domain or Auth-Fail domain when the authentication server becomes reachable
- Permitting MAC move between member ports in a TC group
- Enabling SNMP notifications for port security
- Enabling port security user logging

Enabling port security

Restrictions and guidelines

When you configure port security, follow these restrictions and guidelines:

- Executing the **`undo port-security enable`** command to disable port security will log off online users (if any).
- Enabling or disabling port security resets the following security settings to the default:
  - 802.1X access control mode, which is MAC-based.
  - Port authorization state, which is **auto**.

  These settings are not configurable after port security is enabled.

For more information about 802.1X authentication and MAC authentication configuration, see "Configuring 802.1X" and "Configuring MAC authentication."

Prerequisites

Before you enable port security, disable 802.1X and MAC authentication globally.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable port security.
   ```
   port-security enable
   ```
   By default, port security is disabled.

Setting the port security mode

Restrictions and guidelines

You can specify a port security mode when port security is disabled, but your configuration cannot take effect.

Changing the port security mode of a port logs off the online users of the port.

Do not enable 802.1X authentication or MAC authentication on a port where port security is enabled.

After enabling port security, you can change the port security mode of a port only when the port is operating in noRestrictions (the default) mode. To change the port security mode for a port in any

other mode, first use the **undo port-security port-mode** command to restore the default port security mode.

The device supports the URL attribute assigned by a RADIUS server in the following port security modes:

- mac-authentication.
- mac-else-userlogin-secure.
- mac-else-userlogin-secure-ext.
- userlogin-secure.
- userlogin-secure-ext.
- userlogin-secure-or-mac.
- userlogin-secure-or-mac-ext.
- userlogin-withoui.

During authentication, the HTTP or HTTPS requests of a user are redirected to the Web interface specified by the server-assigned URL attribute. After the user passes the Web authentication, the RADIUS server records the MAC address of the user and uses a DM (Disconnect Message) to log off the user. When the user initiates 802.1X or MAC authentication again, it will pass the authentication and come online successfully.

When the port security mode is **macAddressAndUserLoginSecureExt** on a port, follow these restrictions and guidelines:

- To make sure the 802.1X clients attached to the port can initiate authentication, enable unicast trigger on the port by using the **dot1x unicast-trigger** command.
- The MAC authentication guest VLAN or VSI on the port does not take effect. For the temporary MAC authentication users to access a limited set of resources, configure an 802.1X guest VLAN or VSI on the port.
- If accounting is not required for the temporary MAC authentication users, configure different ISP domains for MAC authentication users and 802.1X users. In the ISP domain for MAC authentication users, set the accounting method to none.

To perform 802.1X MAC bypass authentication for clients incapable of sending EAP messages on a port in userLoginMab mode, enable 802.1X unicast trigger on the port by executing the **dot1x unicast-trigger** command.

To redirect the HTTPS requests of port security users, specify the HTTPS redirect listening port on the device. For more information, see HTTP redirect in *Layer 3—IP Services Configuration Guide*.

Prerequisites

Before you set a port security mode for a port, complete the following tasks:

- Disable 802.1X and MAC authentication.
- If you are configuring the autoLearn mode, set port security's limit on the number of secure MAC addresses. You cannot change the setting when the port is operating in autoLearn mode.

Procedure

1. Enter system view.

   system-view

2. Set an OUI value for user authentication.

   port-security oui index *index-value* **mac-address** *oui-value*

   By default, no OUI values are configured for user authentication.

   This command is required only for the **userlogin-withoui** mode.

   You can set multiple OUIs, but when the port security mode is **userlogin-withoui**, the port allows one 802.1X user and only one user that matches one of the specified OUIs.

3. Enter interface view.

   interface *interface-type interface-number*

4. Set the port security mode.

   port-security port-mode { **autolearn** | **mac-and-userlogin-secure-ext** | **mac-authentication** | **mac-else-userlogin-secure** | **mac-else-userlogin-secure-ext** | **secure** | **userlogin** | **userlogin-mab** | **userlogin-secure** | **userlogin-secure-ext** | **userlogin-secure-or-mac** | **userlogin-secure-or-mac-ext** | **userlogin-withoui** }

   By default, a port operates in noRestrictions mode.

Setting port security's limit on the number of secure MAC addresses on a port

About this task

You can set the maximum number of secure MAC addresses that port security allows on a port for the following purposes:

- Controlling the number of concurrent users on the port.

  For a port operating in a security mode (except for autoLearn and secure), the upper limit equals the smaller of the following values:

  - The limit of the secure MAC addresses that port security allows.
  - The limit of concurrent users allowed by the authentication mode in use.

- Controlling the number of secure MAC addresses on the port in autoLearn mode.

  You can also set the maximum number of secure MAC addresses that port security allows for specific VLANs or each VLAN on a port. When the number of secure MAC addresses reaches the upper limit, the port transitions to secure mode. In secure mode, a port cannot learn MAC addresses.

Port security's limit on the number of secure MAC addresses on a port is independent of the MAC learning limit described in MAC address table configuration. For more information about MAC address table configuration, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the maximum number of secure MAC addresses allowed on a port.

   port-security max-mac-count *max-count* [**vlan** [*vlan-id-list*]]

   By default, port security does not limit the number of secure MAC addresses on a port.

Configuring secure MAC addresses

About secure MAC addresses

For more information about secure MAC addresses, see "Configuring secure MAC addresses."

Restrictions and guidelines

You can bind a secure MAC address to only one port in a VLAN.

You cannot add a MAC address to a VLAN as a static secure MAC address if it has been added as a sticky MAC address in that VLAN, and vice versa.

Prerequisites

Before you configure secure MAC addresses, complete the following tasks:

- Set port security's limit on the number of MAC addresses on the port. Perform this task before you enable autoLearn mode.
- Set the port security mode to autoLearn.
- Configure the port to permit packets of the specified VLAN to pass or add the port to the VLAN. Make sure the VLAN already exists.

Adding a static secure MAC address

1. Enter system view.

   system-view
2. Add a static secure MAC address.
   - Add a static secure MAC address in system view.

     port-security mac-address security *mac-address* **interface** *interface-type interface-number* **vlan** *vlan-id*
   - Execute the following commands in sequence to add a static secure MAC address in interface view:

     interface *interface-type interface-number*

     port-security mac-address security *mac-address* **vlan** *vlan-id*

   By default, no static secure MAC addresses exist.

Adding a sticky MAC address

About this task

When port security is enabled, the MAC addresses learned on a port in autoLearn mode are sticky MAC addresses by default. The following information describes the procedure to add a sticky MAC address manually.

Procedure

1. Enter system view.

   system-view
2. Add a sticky MAC address.
   - Add a sticky MAC address in system view.

     port-security mac-address security sticky *mac-address* **interface** *interface-type interface-number* **vlan** *vlan-id*
   - Execute the following commands in sequence to add a sticky MAC address in interface view:

     interface *interface-type interface-number*

     port-security mac-address security sticky *mac-address* **vlan** *vlan-id*

By default, no manually configured sticky MAC addresses exist.

Converting sticky MAC addresses to dynamic secure MAC addresses

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Convert sticky MAC addresses to dynamic secure MAC addresses.
   port-security mac-address dynamic

   By default, sticky MAC addresses can be saved to the configuration file. Once saved, they can survive a device reboot.

Configuring secure MAC address aging

About this task

By default, secure MAC addresses do not age out. This results in the following issues:

- If a legitimate user leaves a port and an illegitimate user uses the legitimate user's source MAC to access the network, the legitimate user cannot reconnect.
- When legitimate users move from one port to another port within the same VLAN, they cannot come online from the new port if their secure MAC entries on the original port do not age out.
- Legitimate users who have left still occupy the MAC address resources on the port, preventing other legitimate users from connecting to the network.

To enhance port security and improve port resource usage, you can have certain types of secure MAC addresses periodically age out.

Setting the secure MAC aging timer

1. Enter system view.
   system-view
2. Set the secure MAC aging timer.
   port-security timer autolearn aging [**second**] *time-value*

   By default, secure MAC addresses do not age out.

Enabling inactivity aging for secure MAC addresses

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable inactivity aging for secure MAC addresses.
   port-security mac-address aging-type inactivity

   By default, the inactivity aging feature is disabled for secure MAC addresses.

Configuring NTK

About this task

The NTK feature checks the destination MAC address in outbound frames to make sure frames are forwarded only to trustworthy devices.

The NTK feature supports the following modes:

- **ntkonly**—Forwards only unicast frames with a known destination MAC address.
- **ntk-withbroadcasts**—Forwards only broadcast and unicast frames with a known destination MAC address.
- **ntk-withmulticasts**—Forwards only broadcast, multicast, and unicast frames with a known destination MAC address.
- **ntkauto**—Forwards only broadcast, multicast, and unicast frames with a known destination MAC address, and only when the port has online users.

Restrictions and guidelines

The NTK feature drops any unicast frame with an unknown destination MAC address.

Not all port security modes support triggering the NTK feature. For more information, see the port security modes table in "Workflow in a port security mode."

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the NTK feature.

   port-security ntk-mode { **ntk-withbroadcasts** | **ntk-withmulticasts** | **ntkauto** | **ntkonly** }

   By default, NTK is disabled on a port and all frames are allowed to be sent.

Configuring intrusion protection

About this task

Intrusion protection takes one of the following actions on a port in response to illegal frames:

- **blockmac**—Adds the source MAC addresses of illegal frames to the blocked MAC address list, and then discards frames sourced from blocked MAC addresses for a period set by the block timer. A blocked MAC address will be unblocked when the block timer expires.
- **disableport**—Disables the port until you bring it up manually.
- **disableport-temporarily**—Disables the port for a period of time. The period can be configured with the **port-security timer disableport** command.

If the action is **disableport** or **disableport-temporarily**, you can also enable strict intrusion protection to enhance security. With strict intrusion protection, the port shuts down when it receives a frame whose source MAC address is a secure MAC address on another port in the same VLAN.

Restrictions and guidelines

On a port operating in either macAddressElseUserLoginSecure mode or macAddressElseUserLoginSecureExt mode, intrusion protection is triggered only after both MAC authentication and 802.1X authentication fail for the same frame.

Strict intrusion protection takes effect only when the intrusion protection action is **disableport** or **disableport-temporarily**. When strict intrusion protection is enabled on a port, you cannot change the intrusion protection action to **blockmac** on that port. To change the intrusion protection action to **blockmac**, you must first disable strict intrusion protection on that port.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the intrusion protection feature.
   port-security intrusion-mode { **blockmac** | **disableport** | **disableport-temporarily** }
   By default, intrusion protection is disabled.
4. (Optional.) Enable strict intrusion protection.
   port-security strict-intrusion-protection enable
   By default, strict intrusion protection is disabled.
5. Return to system view.
   quit
6. (Optional.) Set the silence timeout period during which a port remains disabled.
   port-security timer disableport *time-value*
   By default, the port silence timeout period is 20 seconds.
7. (Optional.) Set the block timer for blocked MAC addresses.
   port-security timer blockmac *time-value*
   By default, the block timer is 180 seconds.

Configuring an authentication load sharing mode for users attached to M-LAG interfaces

About this task

This feature takes effect only on 802.1X, Web authentication, and MAC authentication users attached to M-LAG interfaces in an M-LAG environment.

In an M-LAG system, the M-LAG member devices exchange configuration information with each other to check for configuration conflicts. If a configuration conflict exists, the M-LAG member devices do not allow new users to come online.

For more information about M-LAG, see *Layer 2—LAN Switching Configuration Guide*.

Restrictions and guidelines

CAUTION:
To avoid user logoffs caused by configuration conflicts, do not change the authentication load sharing mode for users on M-LAG interfaces when port security, 802.1X, Web authentication, or MAC authentication is enabled.

Make sure the M-LAG member devices are consistent in authentication load sharing settings for users attached to M-LAG interfaces.

- **Centralized mode**—Configure both devices to operate in centralized mode for user authentication.

- **Distributed local mode**—Configure both M-LAG member devices to operate in distributed local mode for user authentication.
- **Distributed even-/odd-MAC mode**—Configure one M-LAG member device in distributed even-MAC mode and the other to operate in distributed odd-MAC mode for user authentication.

To ensure correct user data processing, follow these guidelines when you configure the peer aggregate interfaces on each remote access device connected to the M-LAG interfaces:

- If the M-LAG system uses distributed local mode for user authentication, link-aggregation load sharing on the access device can only be based on one of the following criteria:
  - Destination IP address.
  - Destination MAC address.
  - Source IP address.
  - Source MAC address.
- In an 802.1X authentication scenario, you must configure the access device to ignore all packet fields except the source MAC if it uses the default link-aggregation load sharing mode.

In centralized mode, if all member ports of an M-LAG interface belong only to one M-LAG member device and the M-LAG interface forwards authentication traffic, users attached to the M-LAG interface cannot come online. To ensure that users attached to such M-LAG interfaces can come online, do not set the authentication load sharing mode to centralized mode.

For more information about M-LAG, see *Layer 2—LAN Switching Configuration Guide*. For more information about link aggregation load sharing, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Set the authentication load sharing mode for users attached to M-LAG interfaces.

   port-security m-lag load-sharing-mode { **centralized** | **distributed** { **even-mac** | **local** | **odd-mac** } }

   By default, centralized mode applies.

Ignoring authorization information from the server

About this task

You can configure a port to ignore the authorization information received from the server (local or remote) after an 802.1X or MAC authentication user passes authentication.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Ignore the authorization information received from the authentication server.

   port-security authorization ignore

   By default, a port uses the authorization information received from the authentication server.

Configuring MAC move

About this task

Port security MAC move takes effect on online users authenticated through 802.1X authentication, MAC authentication, or Web authentication in the following scenarios:

- **Inter-port move on a device**—An authenticated online user moves between ports on the device. The user VLAN or authentication method might change or stay unchanged after the move.
- **Inter-VLAN move on a port**—An authenticated online user moves between VLANs on a trunk or hybrid port. This mode takes effect only when the packets that trigger authentication are VLAN tagged.

Port security MAC move allows an authenticated online user on one port or VLAN to be reauthenticated and come online on another port or VLAN without going offline first. After the user passes authentication on the new port or VLAN, the system removes the authentication session of the user on the original port or VLAN. This action ensures that the user stays online on only one port in one VLAN.

NOTE:

For MAC authentication, the MAC move feature applies only when MAC authentication single-VLAN mode is used. The MAC move feature does not apply to MAC authentication users that move between VLANs on a port with MAC authentication multi-VLAN mode enabled.

If this feature is disabled, authenticated users must go offline first before they can be reauthenticated successfully on a new port or VLAN to come online.

For a user moving between ports, the port from which the user moves is called the source port and the port to which the user moves is called the destination port.

On the destination port, an authenticated user will reauthenticate in the VLAN authorized on the source port if the source port is enabled with MAC-based VLAN. If that VLAN is not permitted to pass through on the destination port, reauthentication will fail. To avoid this situation, enable VLAN check bypass on the destination port.

Restrictions and guidelines

As a best practice to minimize security risks, enable MAC move only if user roaming between ports is required.

Authenticated users cannot move between ports on a device or between VLANs on a port if the maximum number of online users on the authentication server has been reached.

MAC authentication multi-VLAN mode has higher priority than MAC move for users moving between VLANs on a port. If MAC authentication multi-VLAN mode is enabled, these users can come online in the new VLAN without being reauthenticated. To enable MAC authentication multi-VLAN mode, use the **`mac-authentication host-mode multi-vlan`** command. For more information about MAC authentication multi-VLAN mode, see "Configuring MAC authentication."

When you configure VLAN check bypass for users moving between ports, follow these guidelines:

- To ensure a successful reauthentication, enable VLAN check bypass on a destination port if the source port is enabled with MAC-based VLAN.
- If the destination port is an 802.1X-enabled trunk port, you must configure it to send 802.1X protocol packets without VLAN tags. For more information, see "Configuring 802.1X."

Procedure

1. Enter system view.

   `system-view`

2. Enable MAC move.

   port-security mac-move permit [**port** | **vlan**]

   By default, MAC move is disabled.
3. (Optional.) Enable VLAN check bypass for users moving between ports.
   a. Enter interface view.

      interface *interface-type interface-number*
   b. Enable VLAN check bypass for users moving to the port from other ports.

      port-security mac-move bypass-vlan-check

      By default, the VLAN check bypass feature is disabled.

Enabling overwrite of local MAC entries with remote MAC entries for MAC addresses moved to a remote device

About this task

This feature is typically used in an EVPN or M-LAG environment. It enables the device to overwrite local authenticated MAC entries with remote authenticated MAC entries received from remote devices over tunnels or the peer link immediately, without waiting for the local entries to age out. This overwrite mechanism ensures that the device can promptly update authenticated MAC entries to forward traffic correctly for port security users after they move to a remote device and reauthenticate to the network.

Procedure

1. Enter system view.

   system-view
2. Enable the device to overwrite the local MAC entry for a MAC address with the remote MAC entry for that MAC address after a MAC move

   port-security mac-move overwrite-local

   By default, the device overwrites the local MAC entry for a MAC address with the remote MAC entry for that MAC address after a MAC move.

Enabling the authorization-fail-offline feature

About the authorization-fail-offline feature

IMPORTANT:

The authorization-fail-offline feature takes effect only on port security users that have failed ACL authorization.

The authorization-fail-offline feature logs off port security users that have failed authorization.

A user fails authorization in the following situations:

- The device or server fails to assign the specified authorization attribute to the user.
- The device or server assigns authorization information that does not exist on the device to the user.

This feature does not apply to users that have failed VLAN authorization. The device logs off these users directly.

You can also enable the quiet timer feature for 802.1X or MAC authentication users that are logged off by the authorization-fail-offline feature. The device adds these users to the 802.1X or MAC authentication quiet queue. Within the quiet timer, the device does not process packets from these users or authenticate them. If you do not enable the quiet timer feature, the device immediately authenticates these users upon receiving packets from them.

Prerequisites

For the quiet timer feature to take effect, complete the following tasks:

- For 802.1X users, use the **dot1x quiet-period** command to enable the quiet timer and use the **dot1x timer quiet-period** command to set the timer.
- For MAC authentication users, use the **mac-authentication timer quiet** command to set the quiet timer for MAC authentication.

Procedure

1. Enter system view.

   system-view
2. Enable the authorization-fail-offline feature.

   port-security authorization-fail offline [**quiet-period**]

   By default, this feature is disabled, and the device does not log off users that have failed authorization.

Setting port security's limit on the number of MAC addresses for specific VLANs on a port

About this task

Typically, port security allows the access of the following types of MAC addresses on a port:

- MAC addresses that pass 802.1X authentication or MAC authentication.
- MAC addresses in the MAC authentication guest or critical VLAN, and MAC addresses in the MAC authentication guest or critical VSI, and MAC addresses in the MAC authentication critical microsegment.
- MAC addresses in the 802.1X guest, Auth-Fail, or critical VLAN and MAC addresses in the 802.1X guest, Auth-Fail, or critical VSI.
- MAC addresses that pass Web authentication and MAC addresses in the Web authentication Auth-Fail VLAN.

This feature limits the number of MAC addresses that port security allows to access a port through specific VLANs. Use this feature to prevent resource contentions among MAC addresses and ensure reliable performance for each access user on the port. When the number of MAC addresses in a VLAN on the port reaches the upper limit, the device denies any subsequent MAC addresses in the VLAN on the port.

Restrictions and guidelines

On a port, the maximum number of MAC addresses in a VLAN cannot be smaller than the number of existing MAC addresses in the VLAN. If the specified maximum number is smaller, the setting does not take effect.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

interface *interface-type interface-number*

3. Set port security's limit on the number of MAC addresses for specific VLANs on the port.
   port-security mac-limit *max-number* **per-vlan** *vlan-id-list*

   By default, no limit is set to the number of MAC addresses for specific VLANs on the port.

Enabling open authentication mode

About this task

When planning for initial network deployment, administrators must estimate the number of users and determine their authentication methods. This information prepares them to configure user information on the RADIUS server for future access control. If 802.1X or MAC address authentication is enabled on ports prematurely, some users might fail to come online due to mismatching user information on the RADIUS server, preventing administrators from gathering sufficient user data.

This feature enables access users (802.1X or MAC authentication users) of a port to come online and access the network even if they use nonexistent usernames or incorrect passwords.

Access users that come online in open authentication mode are called open users. Authorization and accounting are not available for open users. To display open user information, use the following commands:

- **display dot1x connection open**.
- **display mac-authentication connection open**.

Open users do not include those users that are normally authenticated to come online from a port in open authentication mode.

Restrictions and guidelines

When you configure open authentication mode, follow these restrictions and guidelines:

- If global open authentication mode is enabled, all ports are enabled with open authentication mode regardless of the port-specific open authentication mode setting. If global open authentication mode is disabled, whether a port is enabled with open authentication mode depends on the port-specific open authentication mode setting.
- The open authentication mode setting has lower priority than the 802.1X Auth-Fail VLAN and the MAC authentication guest VLAN. Open authentication mode does not take effect on a port if the port is also configured with the 802.1X Auth-Fail VLAN or the MAC authentication guest VLAN. For information about 802.1X authentication and MAC authentication, see "802.1X overview," "Configuring 802.1X," and "Configuring MAC authentication."
- The open authentication mode setting has lower priority than the 802.1X Auth-Fail VSI and the MAC authentication guest VSI. Open authentication mode does not take effect on a port if the port is also configured with the 802.1X Auth-Fail VSI or the MAC authentication guest VSI. For information about 802.1X authentication and MAC authentication, see "802.1X overview," "Configuring 802.1X," and "Configuring MAC authentication."

Procedure

1. Enter system view.
   system-view
2. Enable global open authentication mode.
   port-security authentication open global

   By default, global open authentication mode is disabled.
3. Enter interface view.
   interface *interface-type interface-number*

4. Enable open authentication mode on the port.

   port-security authentication open

   By default, open authentication mode is disabled on a port.

Configuring free VLANs for port security

About this task

This feature allows packets from the specified VLANs to not trigger 802.1X or MAC authentication on a port configured with any of the following features:

- 802.1X authentication.
- MAC authentication.
- One of the following port security modes:
  - userLogin.
  - userLoginSecure.
  - userLoginWithOUI.
  - userLoginSecureExt.
  - macAddressWithRadius.
  - macAddressOrUserLoginSecure.
  - macAddressElseUserLoginSecure.
  - macAddressOrUserLoginSecureExt.
  - macAddressElseUserLoginSecureExt.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure free VLANs for port security.

   port-security free-vlan *vlan-id-list*

   By default, no free VLANs for port security exist on a port.

Applying a NAS-ID profile to port security

About this task

By default, the device sends its device name in the NAS-Identifier attribute of all RADIUS requests.

A NAS-ID profile enables you to send different NAS-Identifier attribute strings in RADIUS requests from different VLANs. The strings can be organization names, service names, or any user categorization criteria, depending on the administrative requirements.

For example, map the NAS-ID **companyA** to all VLANs of company A. The device will send **companyA** in the NAS-Identifier attribute for the RADIUS server to identify requests from any Company A users.

Restrictions and guidelines

You can apply a NAS-ID profile to port security globally or on a port. On a port, the device selects a NAS-ID profile in the following order:

1. The port-specific NAS-ID profile.

2. The NAS-ID profile applied globally.

If no NAS-ID profile is applied or no matching binding is found in the selected profile, the device uses the device name as the NAS-ID.

For more information about the NAS-ID profile configuration, see "Configuring AAA."

Procedure

1. Enter system view.
   system-view
2. Apply a NAS-ID profile.
   - Apply a NAS-ID profile globally.
     port-security nas-id-profile *profile-name*
   - Execute the following commands in sequence to apply a NAS-ID profile to an interface:
     interface *interface-type interface-number*
     port-security nas-id-profile *profile-name*

   By default, no NAS-ID profile is applied in system view or in interface view.

Enabling the escape critical VSI feature for 802.1X and MAC authentication users

About this task

The escape critical VSI feature operates on VXLAN networks. It enables 802.1X and MAC authentication users to escape the authentication failure that occurs because the RADIUS server is malfunctioning.

You can enable this feature temporarily to prevent 802.1X and MAC authentication service interruption while you are troubleshooting a malfunctioning RADIUS server.

After the escape critical VSI feature is enabled on a port, the device performs the following operations when 802.1X or MAC authentication is triggered for a user:

1. Dynamically creates an Ethernet service instance that matches the user's access VLAN and MAC address on the access port.
2. Maps the Ethernet service instance to the 802.1X or MAC authentication critical VSI on the port.

The user can then come online without authentication and access resources in the VXLAN associated with the critical VSI.

The escape critical VSI feature does not affect 802.1X or MAC authentication users that have been online before this feature is enabled.

Restrictions and guidelines

For the escape critical VSI feature to work correctly on a port, make sure the port does not have the following settings:

- Web authentication.
- Guest, Auth-Fail, or critical VLAN for 802.1X authentication.
- Guest or critical VLAN for MAC authentication.

You can enable or disable this feature globally on all ports or on a per-port basis.

If the **mac-authentication critical vsi** *critical-vsi-name* **url-user-logoff** command is used in conjunction with this feature, MAC authentication users that have been assigned authorization URLs on the port will be logged off. For more information, see "Configuring MAC authentication."

When you disable the escape critical VSI both globally and on a port, the device logs off the users in the critical VSIs for 802.1X and MAC authentication on that port. The users must perform authentication to come online again on that port.

The escape critical VSI feature does not take effect on a new 802.1X or MAC authentication user if any of the following conditions exists:

- The 802.1X client and the device use different EAP message handling methods.
- 802.1X MAC address binding is enabled on the user's access port, but the MAC address of the 802.1X user is not bound to that port.
- The user's MAC address is an all-zero, all-F, or multicast MAC address.

Prerequisites

Before you enable the escape critical VSI feature on a port, configure an 802.1X critical VSI and a MAC authentication critical VSI on that port. For more information about critical VSI configuration, see "Configuring 802.1X" and "Configuring MAC authentication."

Procedure

1. Enter system view.

   system-view
2. Enable the escape critical VSI feature.
   - Enable the global escape critical VSI feature.

     port-security global escape critical-vsi
   - Execute the following commands in sequence to enable the escape critical VSI feature on a port:

     interface *interface-type interface-number*

     port-security escape critical-vsi

   By default, the escape critical VSI feature is disabled.

Configuring the trigger order for authentication methods on a port

About this task

This feature takes effect only on ports with triple authentication enabled. Triple authentication allows Web authentication, MAC authentication, and 802.1X authentication to be enabled concurrently on a Layer 2 port for user access. Different types of endpoint packets trigger different types of authentication first. For more information, see "Configuring triple authentication."

By default, if 802.1X unicast trigger is enabled, any packdets from endpoints will trigger 802.1X authentication. To enable any endpoint packets to trigger MAC authentication first, use this feature.

A port can run authentication processes concurrently for multiple authentication methods. The failure of one authentication does not affect the processes for other authentication methods. However, if an endpoint passes one authentication on a port, the device handles processes for other authentication methods on the port as follows:

- If the endpoint passes MAC authentication, the device generates a MAC authentication user entry on the port and continues to perform 802.1X authentication for the endpoint on the port. However, the device cannot continue Web authentication for the endpoint on the port.
  - If the endpoint passes 802.1X authentication after MAC authentication, the device generates an 802.1X user entry for the endpoint on the port. The 802.1X user entry overwrites the MAC authentication user entry.

    - If the endpoint does not pass 802.1X authentication after MAC authentication, the MAC authentication user entry is retained on the port. The endpoint can trigger 802.1X authentication again, but it cannot trigger Web authentication.
- If the endpoint fails MAC authentication but passes 802.1X or Web authentication, the device immediately stops all authentication methods on the port except the one the endpoint has passed. In addition, the device can no longer trigger authentication processes for the stopped authentication methods for the endpoint on the port.

Restrictions and guidelines

This feature takes effect only on ports with triple authentication enabled.

This feature causes users that are being authenticated to fail authentication. The users must retrigger authentication to come online. As a best practice to avoid users failing to come online, use this feature with caution.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure the trigger order for authentication methods on the port as MAC authentication, 802.1X authentication, and Web authentication.

   port-security triple-auth-order mac-dot1x-web

   By default, the authentication that is triggered first depends on the type of packets sent from endpoints in a triple authentication environment.

Configuring single-access authentication

About this task

By default, when multiple authentication methods are configured on an interface, a user can proceed with other methods after passing one. For more information, see triple authentication configuration in Security Configuration Guide. For example, if a client sends an EAP message after the client user has come online through MAC authentication, the device performs 802.1X authentication for the user. If 802.1X authentication succeeds, the user will come online as an 802.1X user.

If single-access authentication is enabled, users will not undergo any other authentication methods after they have authenticated with one method.

Restrictions and guidelines

If multi-authentication mode is used, this feature does not take effect.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable single-access authentication.

   port-security single-access enable

   By default, single-access authentication is disabled. When multiple authentication methods are configured on an interface, users can proceed with other methods of authentication after passing one.

Specifying a preauthentication domain for port security users on a port

About this task

A preauthentication domain accommodates 802.1X, Web authentication, and MAC authentication users that have not performed authentication. A preauthentication domain is applicable to the following scenarios:

- A user accesses the network for the first time. This scenario is applicable only to 802.1X and Web authentication users.
- A user fails authentication, but no Auth-Fail domain is configured.
- No server is reachable, but the critical domain is not configured.

When a port is configured with a preauthentication domain, authentication users that access that port will be assigned authorization attributes (including ACL, VSI, , microsegment, and VLAN) in the preauthentication domain after they are assigned to the preauthentication domain. They can access only network resources permitted in the preauthentication domain. If they pass authentication, AAA will assign new authorization information to them.

Restrictions and guidelines

If the ACL, VSI, , microsegment, and VLAN authorization settings in the current preauthentication domain have changes, the changes take effect only on users that are assigned to the preauthentication domain after the changes are made. Users that have been assigned to the preauthentication domain before the changes are made still use the original settings.

On a port, port security preauthentication domain is mutually exclusive with the following settings:

- 802.1X guest VLAN, guest VSI, Auth-Fail VLAN, Auth-Fail VSI, critical VLAN, critical VSI, critical microsegment, and critical profile settings.
- MAC authentication guest VLAN, guest VSI, critical VLAN, critical VSI, critical microsegment, and critical profile settings.
- Web authentication Auth-Fail VLAN settings.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Specify a preauthentication domain for port security users.

   port-security pre-auth domain *isp-name*

   By default, no preauthentication domain is specified for port security users on a port.

Specifying a domain for port security users redirected to an unavailable URL

About this task

During user authentication, if the Web server specified by the redirect URL is unavailable, users cannot be redirected to the Web authentication page on the Web server. As a result, the users cannot come online. To allow users to access the resources in an ISP domain when the redirect URL is unavailable, use this feature to specify that ISP domain for the users.

Restrictions and guidelines

This feature is applicable only to MAC authentication and Web authentication users.

This feature is mutually exclusive with the following 802.1X, MAC authentication, and Web authentication settings:

- Guest VLAN and VSI settings.
- Auth-Fail VLAN and VSI settings.
- Critical VLAN, VSI, and microsegment settings.
- Critical profile settings.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify a domain for port security users redirected to an unavailable URL.
   port-security url-unavailable domain *isp-name*
   By default, no domain is specified for port security users redirected to an unavailable URL.

Configuring static users for port access authentication

Configuring a static user range for port access authentication

About this task

Typically, administrators assign static IP addresses to dumb terminals such as printers. For such users, you can configure them as static users to facilitate flexible authentication. After you configure a dumb terminal as a static user, the device can use the static user information such as the user IP address as the username to perform authentication for the dumb terminal on the user's access interface. For this purpose, make sure 802.1X, Web authentication, or MAC authentication is enabled on the user's access interface.

The device uses the following rules to handle static users:

- If two users have different IP addresses and MAC addresses, the users are different static user. They both can come online.
- If a user that has the same MAC address as an online static user attempts to come online, the device does not trigger authentication for the new user, regardless of whether the users use the same IP address. To update the IP addresses of static users, use the **port-security static-user update-ip enable** command.
- If users that have the same IP address but different MAC addresses come online, the device handles the users as follows:
  - If a MAC address has been bound to the IP address, the user that has the bound MAC address can come online. Users with other MAC addresses cannot trigger authentication to come online.
  - If no MAC address is bound to the IP address, the device allows all users that have IP addresses belonging to a static user IP range to trigger authentication to come online.

Restrictions and guidelines

Modification to a static user range does not affect static users that are already online. The modification takes effect only on static users that will come online.

In the public network or the same VPN instance, the IP address ranges for all static user ranges cannot overlap.

When the usernames of static users are their IP or MAC addresses, do not enable RESTful server-assisted automatic MAC authentication user recovery. If you enable RESTful server-assisted automatic MAC authentication user recovery, the device will recover static users as MAC authentication users after the device reboots or recovers from a failure. For more information about RESTful server-assisted automatic MAC authentication user recovery, see "Configuring MAC authentication."

Procedure

1. Enter system view.

   system-view

2. Configure a static user range for port access authentication.

   port-security static-user { **ip** | **ipv6** } *start-ip-address* [*end-ip-address*] [**vpn-instance** *vpn-instance-name*] [**domain** *isp-name* | [**interface** *interface-type interface-number* [**detect**]] **vlan** *vlan-id* | **mac** *mac-address* | **keep-online**] *

   By default, no static user ranges are configured for port access authentication.

3. (Optional.) Configure the username format used by static users when they come online.

   port-security static-user user-name-format { **ip-address** | **mac-address** | **system-name** }

   By default, the username of a static user is in the format of *SysnameIP*, in which *Sysname* is the name of the access device and *IP* is the user IP address.

4. (Optional.) Configure the user account format when MAC addresses of static users are used as their usernames.

   port-security static-user user-name-format mac-address { **one-section** | { **six-section** | **three-section** } **delimiter** { **colon** | **hyphen** } } [**uppercase**] [**password-with-mac**]

   By default, a static user does not have a password when its MAC address is used as its username. The MAC address contains three hyphen-separated sections and letters in the MAC address are in lower case.

5. (Optional.) Configure a password for static users.

   port-security static-user password { **cipher** | **simple** } *string*

   By default, no password is configured for static users.

6. (Optional.) Set the offline detect period for static users.

   port-security static-user timer offline-detect time-value

   By default, the offline detect period is 5 minutes for static users.

7. (Optional.) Set the interval at which the device actively sends ARP packets to trigger authentication for static users.

   port-security static-user timer detect-period *time-value*

   By default, the device actively sends ARP packets to trigger authentication for static users at intervals of 3 minutes.

Enabling static user IP update

About this task

After you use the **port-security static-user** command to configure an IP address range for a static user range, endpoints at IP addresses in the specified IP address range will come online as static users. If the IP address of an endpoint changes, the endpoint might send abnormal ARP packets to the access device when it comes online. The source IP address of these ARP packets does not belong to the specified IP address range. This issue triggers the device to update the IP address of the endpoint when static user IP update is enabled. After address update, the endpoint is no longer a static user. As a result, the endpoint is logged off.

By default, the device does not update IP addresses for static users when it receives ARP packets with source IP address not belonging to the specified IP address range from these users. This setting prevents the ARP packets from logging off online static users. To trace IP address changes for endpoints, you can enable static user IP update to allow the device to update the IP addresses of static users.

Restrictions and guidelines

Use static user IP update in conjunction with DHCP snooping, ARP snooping, DHCPv6 snooping, or ND snooping. To receive notifications about IP address changes from a snooping module, you must enable the corresponding snooping feature.

Procedure

1. Enter system view.
   system-view
2. Enable static user IP update.
   port-security static-user update-ip enable
   By default, static user IP update is disabled.

Setting the maximum number of concurrent static users allowed on a port

About this task

Set the maximum number of concurrent static users on a port to prevent the system resources from being overused. When the maximum number is reached, the port denies subsequent static users.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the maximum number of concurrent static users allowed on the port.
   port-security static-user max-user *max-number*
   By default, a port supports a maximum of 4294967295 concurrent static users.

Specifying an ACL to match the MAC addresses of static users

About this task

Typically, endpoints that match static user IP ranges come online as static users. However, the device recognizes the endpoints as MAC authentication users instead of static users in the following situations:

- The first packet sent by an endpoint is a Layer 2 packet that does not contain an IP address. In this situation, the packet triggers MAC authentication first.
- An endpoint has both IPv4 and IPv6 addresses and the first packet sent by the endpoint is an IPv6 packet, but only static user IPv4 ranges are configured on the device. In this situation, the packet triggers MAC authentication first.

To resolve the issues, configure this feature to use MAC address as the criterion to match static users. With this feature, the device allows users that match the specified ACL to trigger authentication and come online only as static users. The users cannot trigger other authentication processes.

Restrictions and guidelines

The specified ACL must be a Layer 2 ACL. The ACL can contain only permit rules with the source MAC range criteria.

Procedure

1. Enter system view.

   system-view

2. Specify an ACL to match the MAC addresses of static users.

   port-security static-user match-mac acl *acl-number*

   By default, no ACL is specified to match the MAC addresses of static users.

Configuring a port security authentication profile

About this task

To implement fast port security authentication on users, the device uses port security authentication profiles for unified management of the access authentication configuration. In a port security authentication profile, you can bind 802.1X and MAC authentication access profiles and configure the authentication order to control user access.

After an interface is bound to a port security authentication profile, the interface uses the configuration of the bound profile to perform authentication for access users.

- For functions available in both interface view and port security authentication profile view (commands might differ), the functions configured in interface view are deleted regardless of whether they are configured in the profile view or not. To use those functions on the port, configure them in the bound port security authentication profile.
- For the functions available only in interface view, they can take effect on the interface after being configured.
- The authentication mode used on a port is determined by the 802.1X access profile and MAC authentication access profile bound to the port security authentication profile.

After an interface is bound to a port security authentication profile, the interface supports only MAC-based authentication. If you bind a MAC authentication access profile to the port security authentication profile, the interface will use MAC authentication. If you bind an 802.1X access profile

to the port security authentication profile, the interface will use 802.1X authentication in MAC-based access control.

Restrictions and guidelines

A port security authentication profile can be bound to different interfaces. An interface can be bound to only one port security authentication profile. To change the bound port security authentication profile of an interface, you must first unbind the profile from the interface.

After the authentication profile bound to an interface takes effect, deleting the bound authentication profile will cause abnormal disconnection of online users on the interface.

To avoid authentication anomalies, do not execute the **dot1x port-method portbased** command on an interface that is bound to a port security authentication profile.

Procedure

1. Enter system view.
   system-view
2. Create a port security authentication profile and enter its view.
   port-security authentication-profile name *profile-name*
   By default, no port security authentication profiles exist.
3. Bind an 802.1X access profile to the port security authentication profile.
   dot1x access-profile *profile-name*
   By default, no 802.1X access profile is bound to a port security authentication profile.
4. Bind a MAC authentication access profile to the port security authentication profile.
   mac-authentication access-profile *profile-name*
   By default, no MAC authentication access profile is bound to a port security authentication profile.
5. Exit port security authentication profile view.
   quit
6. Enter interface view.
   interface *interface-type interface-number*
7. Bind a port security authentication profile to the interface.
   port-security authentication-profile *profile-name*
   By default, no port security authentication profile is bound to an interface.

Configuring the port security authentication order (port security authentication profile view)

About this task

You can configure the access authentication order on a port enabled with both 802.1X and MAC authentication methods.

- In **dot1x-mac** order, for a port to perform MAC authentication and assign an authorization VLAN or authorization VSI before it joins the 802.1X guest VLAN or guest VSI, enable parallel 802.1X and MAC authentication processing by using the **port-security auth-order dot1x-mac parallel** command and enable 802.1X guest VLAN or VSI assignment delay. For information about the commands for enabling 802.1X guest VLAN or VSI assignment delay, see 802.1X commands in Security Command Reference.

- In **mac-dot1x** order, to allow a user to go online only after the user passes both MAC and 802.1X authentication, enable multi-authentication mode by using the **port-security auth-order mac-dot1x multiple** command.

Restrictions and guidelines

Changing the access authentication order by using the **port-security auth-order** command will result in authentication failure for users that are currently being authenticated. The users must trigger authentication again in order to go online. To avoid such authentication failures, change the authentication order only when necessary.

If parallel 802.1X and MAC authentication processing is enabled, do not configure MAC authentication delay as a best practice.

Procedure

1. Enter system view.

   system-view

2. Enter port security authentication profile view.

   port-security authentication-profile name *profile-name*

   By default, no port security authentication profiles exist.

3. Configure the port security authentication order.

   port-security auth-order { **dot1x-mac** [**parallel**] | **mac-dot1x** [**multiple**] }

   By default, after a port receives a packet with unknown source MAC address, it performs 802.1X authentication and then MAC authentication for the user.

Configuring port security access policies

About this task

To simplify port security configuration, you can configure a port security access policy and uniformly apply it to all interfaces. By configuring match criteria and actions in port security access policy view, you can control port access users more granularly.

Restrictions and guidelines

A port security access policy only takes effect on users that come online for the first time, and does not affect the re-authentication process of existing online users.

Procedure

1. Enter system view.

   system-view

2. Create a port security access policy and enter its view.

   port-security access-policy *policy-name*

   By default, no port security access policy exists.

3. Configure the match criteria and actions for port security access users.

   if-match [**not**] **acl mac** *acl-number* **action access-type** { **dot1x** | **mac-auth** | **static** | **web-auth** } *

   By default, no match criteria and actions are configured for port security access users.

4. Apply the port security access policy globally.

   port-security apply access-policy *policy-name*

   By default, no port security access policy is applied globally.

Configuring the action to be taken on online users when their access ports go down

About this task

By default, the device immediately logs off online users when their access ports go down. When the ports come up, the users must be reauthenticated to come online. To prevent users from having to repeatedly be reauthenticated and come online in the event of frequent port flapping, you can configure the following actions for online users as needed:

- **keep-online**—Allows online users to stay online when their access ports go down. When the ports come up, the users can come online without being reauthenticated.
- **offline-delay**—Delays logging off online users when their access ports go down.
  - If the access ports come up before the delay time expires, the users can come online without being reauthenticated.
  - If the access ports do not come up before the delay time expires, the users are logged off when the delay time expires. When the ports come up, the users must be reauthenticated to come online.

Restrictions and guidelines

This feature takes effect for online users on a port only when the port automatically goes down due to link abnormalities. It does not take effect when the port goes down manually by executing the **shutdown** command.

This feature takes effect for online users on a port only if you configure it when that access port is up. It does not take effect for online users on a port if that access port is down when you configure it. In this case, any modification or deletion to the feature configuration cannot take effect on that access port.

Procedure

1. Enter system view.

   system-view
2. Enter port security authentication profile view.

   port-security authentication-profile name *profile-name*

   By default, no port security authentication profiles exist.
3. Configure the action to be taken on online users when their access ports go down.

   port-security link-down action { **keep-online** | **offline-delay** *delay-value* }

   By default, the device immediately logs off online users when their access ports go down.

Setting port security timers

About this task

Port security supports the following timers for users that have not performed authentication or that have failed authentication:

- **Periodic reauthentication timer**—Sets the interval at which the device initiates reauthentication for online 802.1X, Web authentication, or MAC authentication users in the specified domain.
- **User aging timer**—Sets the period that the device must wait before it can remove online 802.1X, Web authentication, or MAC authentication users from the specified domain.

Procedure

1. Enter system view.

   system-view

2. Set a port security timer for specific users.

   port-security timer { **reauth-period** { **auth-fail-domain** | **preauth-domain** } | **user-aging** { **auth-fail-domain** | **critical-domain** | **preauth-domain** } } *time-value*

   By default, the period for the periodic reauthentication timer is 600 seconds and the period for the user aging timer is 23 hours.

Configuring the maximum number of reauthentication attempts for users in the preauthentication domain or Auth-Fail domain

About this task

By default, the device performs periodic reauthentication for users in the preauthentication domain and Auth-Fail domain, and the number of reauthentications is not limited. Because of limited system resources, unlimited number of reauthentications without success can lead to resource contention and degraded device performance. To ensure device performance, use this feature to set the maximum number of reauthentication attempts, preventing users from occupying system resources for an extended period.

With this feature, after the maximum number of reauthentications is reached for a preauthentication or Auth-Fail domain user, the device will not trigger periodic reauthentication for that user. The user remains in the current domain and can initiate reauthentication from the client.

Restrictions and guidelines

This feature takes effect only on users who join the preauthentication domain or Auth-Fail domain after the feature command is executed.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the maximum number of reauthentication attempts for users in the preauthentication domain or Auth-Fail domain.

   port-security re-authenticate max-attempt { **auth-fail-domain | preauth-domain** } *max-attempt*

   By default, the device does not limit the number of reauthentication attempts for users in the preauthentication domain or Auth-Fail domain.

Enabling immediate reauthentication for users in the preauthentication domain or Auth-Fail domain when the authentication server becomes reachable

About this task

When all the authentication servers are unreachable or have failed, users might be assigned to the preauthentication domain or Auth-Fail domain. In normal conditions, when the periodic reauthentication feature is enabled for users in the preauthentication domain or Auth-Fail domain, the device triggers reauthentication for users only after the set reauthentication period ends. To have the device immediately trigger reauthentication for these users when any one of the authentication servers become reachable, use this feature.

When the device triggers reauthentication for preauthentication or Auth-Fail domain users, the device sets the maximum reauthentication attempts for them to the value set by using the **port-security re-authenticate max-attempt** command.

Procedure

1. Enter system view.

   system-view

2. Enable immediate reauthentication for users in the preauthentication domain or Auth-Fail domain when the authentication server becomes reachable.

   port-security reauth-trigger server-reachable { **auth-fail-domain** | **preauth-domain** }

   By default, when the authentication server changes from unreachable to reachable, the device does not immediately trigger reauthentication for users in the preauthentication domain or Auth-Fail domain.

Permitting MAC move between member ports in a TC group

About this task

Application scenarios

When the network topology changes, the STP module sends a topology change (TC) event message to notify relevant devices that the network topology has changed. TC events might cause traffic forwarding exceptions on a member port in a TC group.

To resolve this issue, use this feature to permit MAC move between member ports in a TC group when the network topology changes. MAC move allows authenticated online users on a member port in a TC group to move to the other member port in the same TC group without being authenticated again. The process is as described in "Operating mechanism."

Use this feature on the device if the device is connected to users that cannot actively send packets to trigger MAC move when the network topology changes.

Operating mechanism

The operating mechanism of this feature is as follows:

- If a member port in a TC group is up and receives a TC event message, the device searches for online authenticated users that come online from that port. In addition, the device sends ARP or

NS detection packets to these users at detection intervals through the other member port in the same TC group.

- If the other member port receives a response packet for a user, that user moves to the other member port and comes online without being authenticated.
- If the other member port does not receive any response packets for a user after the device has made the maximum number of attempts for sending a detection packet, the device determines that the network topology of that TC group does not change. It does not move the user to the other member port.

- If the network topology changes because a member port in a TC group goes down, the device does not wait to receive TC event messages sent by the STP module or actively detect online authenticated users on that port from the other member port. Instead, it immediately moves the online authenticated users on that port to the other member port without authenticating them. To detect whether the users can come online correctly on the other member port, you can enable offline detection or ARP or NS packet detection on the other member port.

For more information about TC groups, see spanning tree configuration in *Layer 2—LAN Switching Configuration Guide*.

Restrictions and guidelines

This feature takes effect only on static users, MAC authentication users, and 802.1X users.

As a best practice to ensure successful MAC move between member ports in a TC group, the member ports in that TC group must use the same settings.

Procedure

1. Enter system view.

   `system-view`

2. Allow authenticated online users to move between member ports in the same TC group without being authenticated again.

   `port-security topology-change free-mac-move`

   By default, the device does not allow authenticated online users to move between member ports in the same TC group without being authenticated again.

3. Set the interval at which the device actively sends ARP or NS detection packets when the network topology changes.

   `port-security topology-change detect-period` *`time-value`*

   By default, the device actively sends ARP or NS detection packets at intervals of 5 seconds when the network topology changes.

4. Set the maximum number of attempts for sending an ARP or NS detection packet when the network topology changes.

   `port-security topology-change detect-retry` *`retries`*

   By default, the device attempts to send an ARP or NS detection packet for a maximum of three times when the network topology changes.

Enabling SNMP notifications for port security

About this task

Use this feature to report critical port security events to an NMS. For port security event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

system-view

2. Enable SNMP notifications for port security.

   snmp-agent trap enable port-security [**ac-creation-failure** | **acl-author-failure** | **acl-author-success** | **address-learned** | **dot1x-failure** | **dot1x-ip-change** | **dot1x-logoff** | **dot1x-logon** | **intrusion** | **intrusion-recover** | **mac-auth-failure** | **mac-auth-logoff** | **mac-auth-logon** | **mac-auth-ip-change** | **mac-auth-not-support** | **ntk-ineffective** | **port-mode-ineffective** | **url-author-failure** | **url-author-success**] *

   By default, SNMP notifications are disabled for port security.

Enabling port security user logging

About this task

This feature enables the device to generate logs about port security users and send the logs to the information center. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

To prevent excessive port security user log entries, use this feature only if you need to analyze abnormal port security user events.

Procedure

1. Enter system view.

   system-view

2. Enable port security user logging.

   port-security access-user log enable [**failed-authorization** | **mac-learning** | **violation** | **vlan-mac-limit**] *

   By default, port security user logging is disabled.

   If you do not specify any parameters, this command enables all types of port security user logs.

Display and maintenance commands for port security

Execute **display** commands in any view:

Task	Command
Display the port security configuration, operation information, and statistics.	**display port-security** [**interface** *interface-type interface-number*]
Display entries for online port security access users.	**display port-security access-user** [**m-lag** [**local** | **peer**]] [**access-type** { **dot1x** | **mac-auth** | **web-auth** | **static** } | **domain** *domain-name* | **microsegment** *microsegment-id* | **online-type** { **auth-fail-domain** | **critical-domain** | **preauth-domain** | **success** | **url-unavailable-domain** } | **slot** *slot-number*] * [**brief**] **display port-security access-user** [**m-lag**

Task	Command
	[**local** | **peer**]] [**access-type** { **dot1x** | **mac-auth** | **web-auth** | **static** } | **domain** *domain-name* | **online-type** { **auth-fail-domain** | **critical-domain** | **preauth-domain** | **success** | **url-unavailable-domain** } | **slot** *slot-number*] *
Display configuration information for port security authentication profiles	**display port-security authentication-profile** [**name** *profile-name*]
Display information about blocked MAC addresses.	**display port-security mac-address block** [**interface** *interface-type interface-number*] [**vlan** *vlan-id*] [**count**]
Display MAC address entries synchronized from the M-LAG peer.	**display port-security mac-address m-lag sync-from-peer** [**user-mac** *mac-address*]
Display MAC address entries synchronized to the M-LAG peer.	**display port-security mac-address m-lag sync-to-peer** [**interface** *interface-type interface-number* | **user-mac** *mac-address*]
Display information about secure MAC addresses.	**display port-security mac-address security** [**interface** *interface-type interface-number*] [**vlan** *vlan-id*] [**count**]
Display static user configuration information.	**display port-security static-user**
Display online static users.	**display port-security static-user connection** [[**m-lag** [**local** | **peer**]] [**interface** *interface-type interface-number* | **online-type** { **auth-fail-domain** | **critical-domain** | **preauth-domain** | **success** } | **slot** *slot-number* | **user-name** *user-name*] | { **ip** | **ipv6** } *ip-address* | **mac** *mac-address*]
Display port security statistics.	**display port-security statistics** [**slot** *slot-number*]
Log off online static users.	**reset port-security static-user** [**interface** *interface-type interface-number* | { **ip** | **ipv6** } *ip-address* | **mac** *mac-address* | **online-type** { **auth-fail-domain** | **critical-domain** | **preauth-domain** | **success** } | **user-name** *user-name*]
Clear port security statistics.	**reset port-security statistics**

Port security configuration examples

Example: Configuring port security in autoLearn mode

Network configuration

As shown in Figure 3, configure GigabitEthernet 1/0/1 on the device to meet the following requirements:

- Accept up to 64 users without authentication.
- Be permitted to learn and add MAC addresses as sticky MAC addresses, and set the secure MAC aging timer to 30 minutes.
- Stop learning MAC addresses after the number of secure MAC addresses reaches 64. If any frame with an unknown MAC address arrives, intrusion protection starts, and the port shuts down and stays silent for 30 seconds.

Figure 3 Network diagram

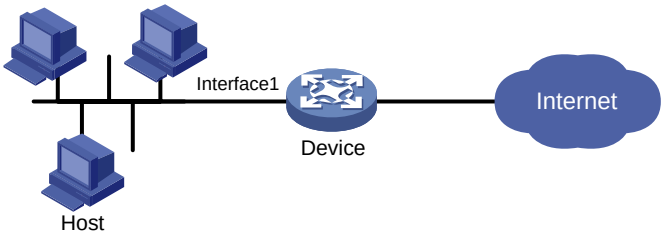


Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Enable port security.

```
<Device> system-view
[Device] port-security enable
```

Set the secure MAC aging timer to 30 minutes.

```
[Device] port-security timer autolearn aging 30
```

Set port security's limit on the number of secure MAC addresses to 64 on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] port-security max-mac-count 64
```

Set the port security mode to autoLearn.

```
[Device-GigabitEthernet1/0/1] port-security port-mode autolearn
```

Configure the port to be silent for 30 seconds after the intrusion protection feature is triggered.

```
[Device-GigabitEthernet1/0/1] port-security intrusion-mode disableport-temporarily
[Device-GigabitEthernet1/0/1] quit
[Device] port-security timer disableport 30
```

Verifying the configuration

Verify the port security configuration.

```
[Device] display port-security interface gigabitethernet 1/0/1
Global port security parameters:
```

```
  Port security                              : Enabled

#
```

Use the **`display port-security interface`** command to verify that the port security mode changes to **secure** after the number of MAC addresses learned by the port reaches 64.

Use the **`display interface`** command to verify that the port will be disabled for 30 seconds after it receives a frame with an unknown MAC address. (Details not shown.)

After the port is re-enabled, delete several secure MAC addresses. (Details not shown.)

Verify that the port security mode of the port changes to **autoLearn**, and the port can learn MAC addresses again. (Details not shown.)

Example: Configuring port security in userLoginWithOUI mode

Network configuration

As shown in Figure 4, a client is connected to the device through GigabitEthernet 1/0/1. The device authenticates the client with a RADIUS server in ISP domain **sun**. If the authentication succeeds, the client is authorized to access the Internet.

- The RADIUS server at 192.168.1.2 acts as the primary authentication server and the secondary accounting server. The RADIUS server at 192.168.1.3 acts as the secondary authentication

server and the primary accounting server. The shared key for authentication is **name**, and the shared key for accounting is **money**.

- All users use the authentication, authorization, and accounting methods of ISP domain **sun**.
- The RADIUS server response timeout time is 5 seconds. The maximum number of RADIUS packet retransmission attempts is 5. The device sends real-time accounting packets to the RADIUS server at 15-minute intervals, and sends usernames without domain names to the RADIUS server.

Configure GigabitEthernet 1/0/1 to allow only one 802.1X user and a user that uses one of the specified OUI values to be authenticated.

Figure 4 Network diagram

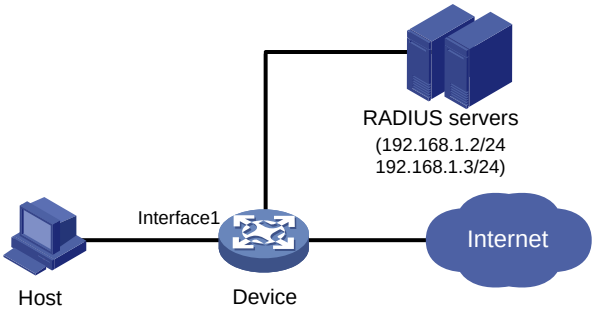

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

The following configuration steps cover some AAA/RADIUS configuration commands. For more information about the commands, see *Security Command Reference*.

Make sure the host and the RADIUS server can reach each other.

1. Configure AAA:

Configure a RADIUS scheme named **radsun**.

```
<Device> system-view
[Device] radius scheme radsun
[Device-radius-radsun] primary authentication 192.168.1.2
[Device-radius-radsun] primary accounting 192.168.1.3
[Device-radius-radsun] secondary authentication 192.168.1.3
[Device-radius-radsun] secondary accounting 192.168.1.2
[Device-radius-radsun] key authentication simple name
[Device-radius-radsun] key accounting simple money
[Device-radius-radsun] timer response-timeout 5
[Device-radius-radsun] retry 5
[Device-radius-radsun] timer realtime-accounting 15
[Device-radius-radsun] user-name-format without-domain
[Device-radius-radsun] quit
```

Configure ISP domain **sun**.

```
[Device] domain sun
[Device-isp-sun] authentication lan-access radius-scheme radsun
[Device-isp-sun] authorization lan-access radius-scheme radsun
```

```
[Device-isp-sun] accounting lan-access radius-scheme radsun
[Device-isp-sun] quit
```

2. Configure 802.1X:

Set the 802.1X authentication method to CHAP. By default, the authentication method for 802.1X is CHAP.

```
[Device] dot1x authentication-method chap
```

Specify ISP domain **sun** as the mandatory authentication domain for 802.1X users on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] dot1x mandatory-domain sun
[Device-GigabitEthernet1/0/1] quit
```

3. Configure port security:

Enable port security.

```
[Device] port-security enable
```

Add five OUI values. (You can add up to 16 OUI values. The port permits only one user matching one of the OUIs to pass authentication.)

```
[Device] port-security oui index 1 mac-address 1234-0100-1111
[Device] port-security oui index 2 mac-address 1234-0200-1111
[Device] port-security oui index 3 mac-address 1234-0300-1111
[Device] port-security oui index 4 mac-address 1234-0400-1111
[Device] port-security oui index 5 mac-address 1234-0500-1111
```

Set the port security mode to userLoginWithOUI.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] port-security port-mode userlogin-withoui
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify that GigabitEthernet 1/0/1 allows only one 802.1X user to be authenticated.

```
[Device] display port-security interface gigabitethernet 1/0/1

```

Example: Configuring port security in macAddressElseUserLoginSecure mode

Network configuration

As shown in Figure 5, a client is connected to the device through GigabitEthernet 1/0/1. The device authenticates the client by a RADIUS server in ISP domain **sun**. If the authentication succeeds, the client is authorized to access the Internet.

Configure GigabitEthernet 1/0/1 of the device to meet the following requirements:

- Allow more than one MAC authenticated user to log on.
- For 802.1X users, perform MAC authentication first and then, if MAC authentication fails, 802.1X authentication. Allow only one 802.1X user to log on.
- Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in upper case.
- Set the total number of MAC authenticated users and 802.1X authenticated users to 64.
- Enable NTK (**ntkonly** mode) to prevent frames from being sent to unknown MAC addresses.

Figure 5 Network diagram

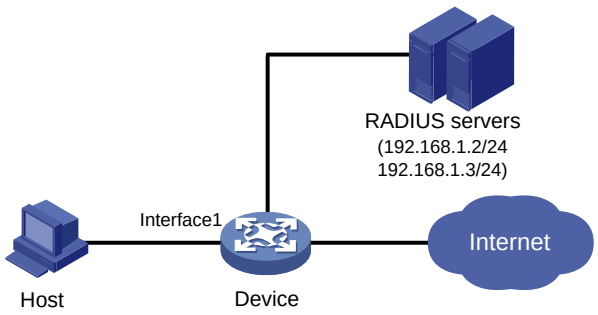

Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Make sure the host and the RADIUS server can reach each other.

1. Configure RADIUS authentication/accounting and ISP domain settings.
2. Configure port security:

   # Enable port security.

   ```
   <Device> system-view
   [Device] port-security enable
   ```

   # Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in upper case.

   ```
   [Device] mac-authentication user-name-format mac-address with-hyphen uppercase
   ```

   # Specify the MAC authentication domain.

   ```
   [Device] mac-authentication domain sun
   ```

   # Set the 802.1X authentication method to CHAP. By default, the authentication method for 802.1X is CHAP.

   ```
   [Device] dot1x authentication-method chap
   ```

   # Set port security's limit on the number of MAC addresses to 64 on the port.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] port-security max-mac-count 64
   ```

   # Set the port security mode to macAddressElseUserLoginSecure.

   ```
   [Device-GigabitEthernet1/0/1] port-security port-mode mac-else-userlogin-secure
   ```

   # Specify ISP domain **sun** as the mandatory authentication domain for 802.1X users.

   ```
   [Device-GigabitEthernet1/0/1] dot1x mandatory-domain sun
   ```

   # Set the NTK mode of the port to ntkonly.

   ```
   [Device-GigabitEthernet1/0/1] port-security ntk-mode ntkonly
   [Device-GigabitEthernet1/0/1] quit
   ```

Verifying the configuration

Verify the port security configuration.

```
[Device] display port-security interface gigabitethernet 1/0/1
Global port security parameters:
   Port security                          : Enabled

```

Verify that frames with an unknown destination MAC address, multicast address, or broadcast address are discarded. (Details not shown.)

Example: Configuring port security for M-LAG

Network configuration

As shown in Figure 6, Device A and Device B authenticate the host users to the Internet. Configure Device A and Device B as follows:

- Use RADIUS servers to perform authentication, authorization, and accounting for the users.
- Form an M-LAG system for node redundancy.
- Set the port security mode to **macAddressWithRadius** on their M-LAG interfaces. Set the authentication load sharing mode to distributed local mode for users attached to the M-LAG interfaces.
- To make sure the source IP address of the RADIUS packets sent for users attached to one member device does not change after a node failover, configure the following settings on each member device:
  - Configure one source IP address for local users and one for users attached to the peer member device. On each member device, use the active and standby M-LAG virtual IP addresses as the local and peer source IP addresses of the outgoing RADIUS packets, respectively.

Figure 6 Network diagram

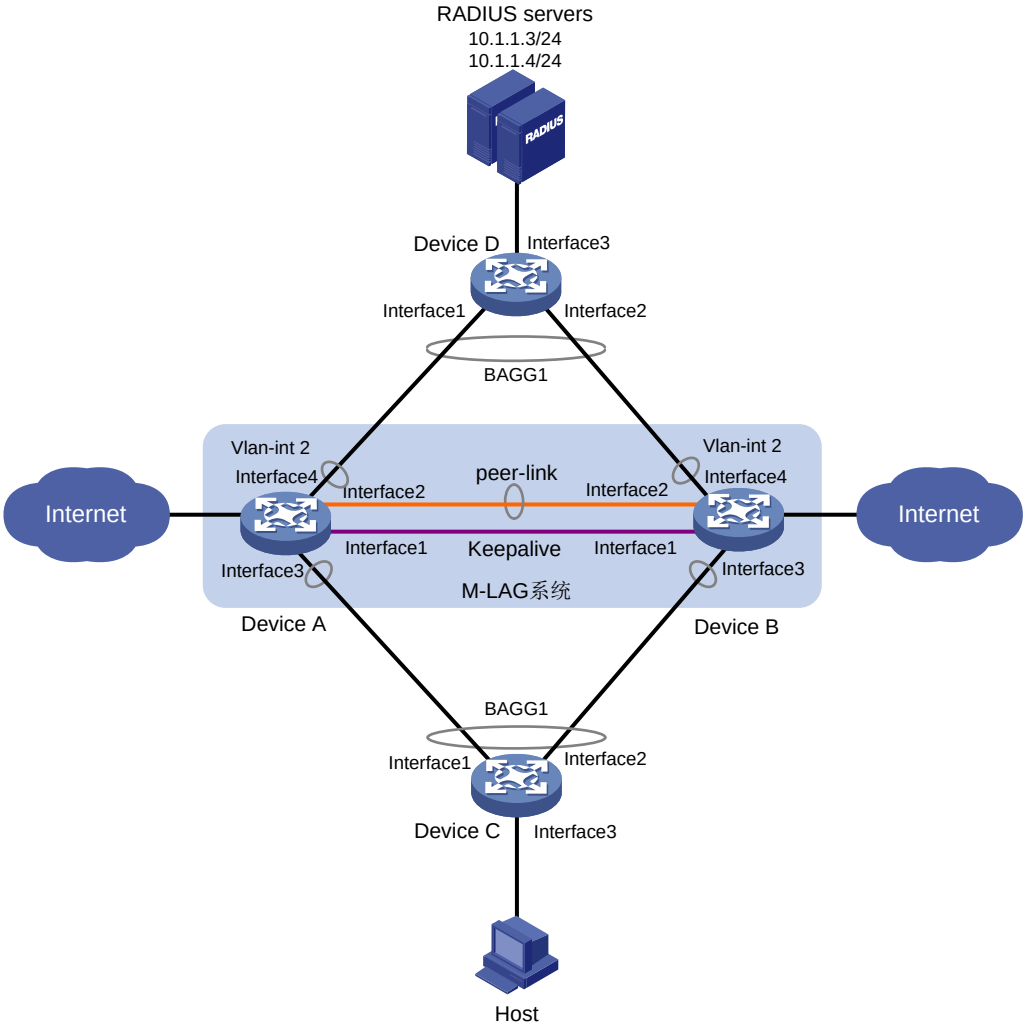

Table 6 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4

Table 7 IP assignment scheme

Device	Interface	M-LAG interface	IP address
Device A (M-LAG1)	GE1/0/1	Keepalive interface	1.1.1.2/24
	BAGG1 (GE1/0/2)	Peer link interface	-
	BAGG2 (GE1/0/4)	M-LAG interface	-
	BAGG3 (GE1/0/3)	M-LAG interface	-
	VLAN-interface 2	-	10.1.1.1/24
Device B (M-LAG2)	GE1/0/1	Keepalive interface	1.1.1.1/24
	BAGG1 (GE1/0/2)	Peer link interface	-

Device	Interface	M-LAG interface	IP address
	BAGG2 (GE1/0/4)	M-LAG interface	-
	BAGG3 (GE1/0/3)	M-LAG interface	-
	VLAN-interface 2	-	-

Restrictions and guidelines

The configuration procedure in this example uses some AAA and RADIUS commands. For more information about these commands, see *Security Command Reference*.

The configuration procedure in this example uses some M-LAG commands. For more information about these commands, see *Layer 2—LAN Switching Command Reference*.

Prerequisites

Make sure the host and RADIUS servers can reach each other.

Configure the RADIUS servers and add user accounts. Make sure the RADIUS servers can provide authentication, authorization, and accounting services.

Procedure

1. Configure Device A:

- Configure AAA:

  # Configure RADIUS scheme **radsun**.

```
<DeviceA> system-view
[DeviceA] radius scheme radsun
[DeviceA-radius-radsun] primary authentication 10.1.1.3
[DeviceA-radius-radsun] primary accounting 10.1.1.4
[DeviceA-radius-radsun] secondary authentication 10.1.1.4
[DeviceA-radius-radsun] secondary accounting 10.1.1.3
[DeviceA-radius-radsun] key authentication simple name
[DeviceA-radius-radsun] key accounting simple money
[DeviceA-radius-radsun] timer response-timeout 5
[DeviceA-radius-radsun] retry 5
[DeviceA-radius-radsun] timer realtime-accounting 15
[DeviceA-radius-radsun] user-name-format without-domain
```

  # Specify 10.1.1.1 as the source IP address of outgoing RADIUS packets for users attached to the local M-LAG interfaces. Specify 10.1.1.2 as the source IP address of outgoing RADIUS packets for users attached to the peer M-LAG interfaces.

```
[DeviceA-radius-radsun] nas-ip m-lag local 10.1.1.1
[DeviceA-radius-radsun] nas-ip m-lag peer 10.1.1.2
[DeviceA-radius-radsun] quit
```

  # Configure ISP domain **sun**.

```
[DeviceA] domain sun
[DeviceA-isp-sun] authentication lan-access radius-scheme radsun
[DeviceA-isp-sun] authorization lan-access radius-scheme radsun
[DeviceA-isp-sun] accounting lan-access radius-scheme radsun
[DeviceA-isp-sun] quit
```

- Configure M-LAG settings:

  # Configure M-LAG system settings.

```
[DeviceA] m-lag system-mac 1-1-1
[DeviceA] m-lag system-number 1
```

```
[DeviceA] m-lag system-priority 123
```

Configure the destination and source IP addresses of keepalive packets.

```
[DeviceA] m-lag keepalive ip destination 1.1.1.1 source 1.1.1.2
```

Configure port GigabitEthernet 1/0/1 to operate in Layer 3 mode and configure the source IP address of keepalive packets as the IP address of this port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-mode route
[DeviceA-GigabitEthernet1/0/1] ip address 1.1.1.2 24
[DeviceA-GigabitEthernet1/0/1] quit
```

Exclude GigabitEthernet 1/0/1 (keepalive interface) from being shut down upon detection of multi-active collisions.

```
[DeviceA] m-lag mad exclude interface gigabitethernet 1/0/1
```

Create Layer 2 aggregate interface **Bridge-Aggregation 1** and set the aggregation mode to dynamic.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation1] quit
```

Assign GigabitEthernet 1/0/2 to aggregation group 1.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/2] quit
```

Configure Layer 2 aggregate interface **Bridge-Aggregation 1** as a peer link interface.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] port m-lag peer-link 1
[DeviceA-Bridge-Aggregation1] quit
```

On the VLAN interface, specify 10.1.1.1 as the M-LAG virtual IPv4 address in active state and specify 10.1.1.2 as the M-LAG virtual IPv4 address in standby state.

```
[DeviceA] vlan 2
[DeviceA-vlan2] quit
[DeviceA] interface vlan-interface 2
[DeviceA-Vlan-interface2] port m-lag virtual-ip 10.1.1.1 24 active virtual-mac
11-1-1
[DeviceA-Vlan-interface2] port m-lag virtual-ip 10.1.1.2 24 standby virtual-mac
11-1-2
[DeviceA-Vlan-interface2] quit
```

Create Layer 2 aggregate interface **Bridge-Aggregation 2** and set the aggregation mode to dynamic.

```
[DeviceA] interface bridge-aggregation 2
[DeviceA-Bridge-Aggregation2] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation2] quit
```

Assign GigabitEthernet 1/0/4 to aggregation group 2.

```
[DeviceA] interface gigabitethernet 1/0/4
[DeviceA-GigabitEthernet1/0/4] port link-aggregation group 2
[DeviceA-GigabitEthernet1/0/4] quit
```

Assign Bridge-Aggregation 2 to M-LAG group 2.

```
[DeviceA] interface bridge-aggregation 2
[DeviceA-Bridge-Aggregation2] port m-lag group 2
[DeviceA-Bridge-Aggregation2] port access vlan 2
[DeviceA-Bridge-Aggregation2] quit
```

Create Layer 2 aggregate interface **Bridge-Aggregation 3** and set the aggregation mode to dynamic.

```
[DeviceA] interface bridge-aggregation 3
[DeviceA-Bridge-Aggregation3] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation3] quit
```

Assign GigabitEthernet 1/0/3 to aggregation group 3.

```
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 3
[DeviceA-GigabitEthernet1/0/3] quit
```

Assign Bridge-Aggregation 3 to M-LAG group 3.

```
[DeviceA] interface bridge-aggregation 3
[DeviceA-Bridge-Aggregation3] port m-lag group 3
[DeviceA-Bridge-Aggregation3] quit
```

- Configure port security settings:

  # Enable port security.

  ```
  [DeviceA] port-security enable
  ```

  # Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hyphenated hexadecimal notation, with letters in upper case.

  ```
  [DeviceA] mac-authentication user-name-format mac-address with-hyphen uppercase
  ```

  # Configure domain **sun** as the global MAC authentication domain on the device.

  ```
  [DeviceA] mac-authentication domain sun
  ```

  # Set the port security mode to **macAddressWithRadius** on Bridge-Aggregation 3.

  ```
  [DeviceA] interface bridge-aggregation 3
  [DeviceA-Bridge-Aggregation3] port-security port-mode mac-authentication
  ```

  # Configure domain **sun** as the MAC authentication domain on Bridge-Aggregation 3.

  ```
  [DeviceA-Bridge-Aggregation3] mac-authentication domain sun
  [DeviceA-Bridge-Aggregation3] quit
  ```

2. Configure Device B:

- Configure AAA settings:

  # Configure RADIUS scheme **radsun**.

  ```
  <DeviceB> system-view
  [DeviceB] radius scheme radsun
  [DeviceB-radius-radsun] primary authentication 10.1.1.3
  [DeviceB-radius-radsun] primary accounting 10.1.1.4
  [DeviceB-radius-radsun] secondary authentication 10.1.1.4
  [DeviceB-radius-radsun] secondary accounting 10.1.1.3
  [DeviceB-radius-radsun] key authentication simple name
  [DeviceB-radius-radsun] key accounting simple money
  [DeviceB-radius-radsun] timer response-timeout 5
  [DeviceB-radius-radsun] retry 5
  [DeviceB-radius-radsun] timer realtime-accounting 15
  [DeviceB-radius-radsun] user-name-format without-domain
  ```

  # Specify 10.1.1.2 as the source IP address of outgoing RADIUS packets for users attached to the local M-LAG interfaces. Specify 10.1.1.1 as the source IP address of outgoing RADIUS packets for users attached to the peer M-LAG interfaces.

  ```
  [DeviceB-radius-radsun] nas-ip m-lag local 10.1.1.2
  [DeviceB-radius-radsun] nas-ip m-lag peer 10.1.1.1
  ```

```
[DeviceB-radius-radsun] quit
```

Configure ISP domain **sun**.

```
[DeviceB] domain sun
[DeviceB-isp-sun] authentication lan-access radius-scheme radsun
[DeviceB-isp-sun] authorization lan-access radius-scheme radsun
[DeviceB-isp-sun] accounting lan-access radius-scheme radsun
[DeviceB-isp-sun] quit
```

- Configure M-LAG settings:

Configure M-LAG system settings.

```
[DeviceB] m-lag system-mac 1-1-1
[DeviceB] m-lag system-number 2
[DeviceB] m-lag system-priority 123
```

Configure the destination and source IP addresses of keepalive packets.

```
[DeviceB] m-lag keepalive ip destination 1.1.1.2 source 1.1.1.1
```

Configure GigabitEthernet 1/0/1 to operate in Layer 3 mode and configure the source IP address of keepalive packets as the IP address of this port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-mode route
[DeviceB-GigabitEthernet1/0/1] ip address 1.1.1.1 24
[DeviceB-GigabitEthernet1/0/1] quit
```

Exclude GigabitEthernet 1/0/1 (keepalive interface) from being shut down upon detection of multi-active collisions.

```
[DeviceB] m-lag mad exclude interface gigabitethernet 1/0/1
```

Create Layer 2 aggregate interface **Bridge-Aggregation 1** and set the aggregation mode to dynamic.

```
[DeviceB] interface bridge-aggregation 1
[DeviceB-Bridge-Aggregation1] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation1] quit
```

Assign GigabitEthernet 1/0/2 to aggregation group 1.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-aggregation group 1
[DeviceB-GigabitEthernet1/0/2] quit
```

Configure Layer 2 aggregate interface **Bridge-Aggregation 1** as a peer link interface.

```
[DeviceB] interface bridge-aggregation 1
[DeviceB-Bridge-Aggregation1] port m-lag peer-link 1
[DeviceB-Bridge-Aggregation1] quit
```

Create VLAN-interface 2. On the VLAN interface, specify 10.1.1.2 as the M-LAG virtual IPv4 address in active state and specify 10.1.1.1 as the M-LAG virtual IPv4 address in standby state.

```
[DeviceB] vlan 2
[DeviceB-vlan2] quit
[DeviceB] interface vlan-interface 2
[DeviceB-Vlan-interface2] port m-lag virtual-ip 10.1.1.2 24 active virtual-mac
11-1-2
[DeviceB-Vlan-interface2] port m-lag virtual-ip 10.1.1.1 24 standby virtual-mac
11-1-1
[DeviceB-Vlan-interface2] quit
```

Create Layer 2 aggregate interface **Bridge-Aggregation 2** and set the aggregation mode to dynamic.

```
[DeviceB] interface bridge-aggregation 2
[DeviceB-Bridge-Aggregation2] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation2] quit
```

Assign GigabitEthernet 1/0/4 to aggregation group 2.

```
[DeviceB] interface gigabitethernet 1/0/4
[DeviceB-GigabitEthernet1/0/4] port link-aggregation group 2
[DeviceB-GigabitEthernet1/0/4] quit
```

Assign Bridge-Aggregation 2 to M-LAG group 2.

```
[DeviceB] interface bridge-aggregation 2
[DeviceB-Bridge-Aggregation2] port m-lag group 2
[DeviceB-Bridge-Aggregation2] port access vlan 2
[DeviceB-Bridge-Aggregation2] quit
```

Create Layer 2 aggregate interface **Bridge-Aggregation 3** and set the aggregation mode to dynamic.

```
[DeviceB] interface bridge-aggregation 3
[DeviceB-Bridge-Aggregation3] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation3] quit
```

Assign GigabitEthernet 1/0/3 to aggregation group 3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-aggregation group 3
[DeviceB-GigabitEthernet1/0/3] quit
```

Assign Bridge-Aggregation 3 to M-LAG group 3.

```
[DeviceB] interface bridge-aggregation 3
[DeviceB-Bridge-Aggregation3] port m-lag group 3
[DeviceB-Bridge-Aggregation3] quit
```

- Configure port security settings:

  # Enable port security.

  ```
  [DeviceB] port-security enable
  ```

  # Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hyphenated hexadecimal notation, with letters in upper case.

  ```
  [DeviceB] mac-authentication user-name-format mac-address with-hyphen uppercase
  ```

  # Configure domain **sun** as the global MAC authentication domain on the device.

  ```
  [DeviceB] mac-authentication domain sun
  ```

  # Set the port security mode to **macAddressWithRadius** on Layer 2 aggregate interface **Bridge-Aggregation 3**.

  ```
  [DeviceB] interface bridge-aggregation 3
  [DeviceB-Bridge-Aggregation3] port-security port-mode mac-authentication
  ```

  # Configure domain **sun** as the MAC authentication domain on Bridge-Aggregation 3.

  ```
  [DeviceB-Bridge-Aggregation3] mac-authentication domain sun
  [DeviceB-Bridge-Aggregation3] quit
  ```

3. Configure Device C:

Create Layer 2 aggregate interface **Bridge-Aggregation 1** and set the aggregation mode to dynamic.

```
<DeviceC> system-view
[DeviceC] interface bridge-aggregation 1
[DeviceC-Bridge-Aggregation1] link-aggregation mode dynamic
[DeviceC-Bridge-Aggregation1] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 1.

```
[DeviceC] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/2
[DeviceC-if-range] port link-aggregation group 1
[DeviceC-if-range] quit
```

4. Configure Device D:

Create Layer 2 aggregate interface **Bridge-Aggregation 1** and set the aggregation mode to dynamic.

```
<DeviceD> system-view
[DeviceD] interface bridge-aggregation 1
[DeviceD-Bridge-Aggregation1] link-aggregation mode dynamic
[DeviceD-Bridge-Aggregation1] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 1.

```
[DeviceD] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/2
[DeviceD-if-range] port link-aggregation group 1
[DeviceD-if-range] quit
```

Verifying the configuration

1. On Device A:

Display M-LAG summary information on Device A to verify that Device A and Device B have formed an M-LAG system.

```
[DeviceA] display m-lag summary
Flags: A -- Aggregate interface down, B -- No peer M-LAG interface configured
       C -- Configuration consistency check failed

Peer-link interface: BAGG1
Peer-link interface state (cause): UP
Keepalive link state (cause): UP

                    M-LAG interface information
M-LAG IF      M-LAG group  Local state (cause)  Peer state  Remaining down time(s)
BAGG2         2            UP                   UP          -
BAGG3         3            UP                   UP          -
```

Display port security settings on Device A.

```
[DeviceA] display port-security interface bridge-aggregation 3
Global port security parameters:
   Port security                          : Enabled

Troubleshooting port security

Cannot set the port security mode

Symptom

Cannot set the port security mode for a port.

Analysis

For a port operating in a port security mode other than noRestrictions, you cannot change the port security mode by using the **`port-security port-mode`** command.

Solution

To resolve the issue:

1. Set the port security mode to noRestrictions.

   ```
   [Device-GigabitEthernet1/0/1] undo port-security port-mode
   ```

2. Set a new port security mode for the port, for example, autoLearn.

   ```
   [Device-GigabitEthernet1/0/1] port-security port-mode autolearn
   ```

3. If the issue persists, contact H3C Support.

Cannot configure secure MAC addresses

Symptom

Cannot configure secure MAC addresses.

Analysis

No secure MAC address can be configured on a port operating in a port security mode other than autoLearn.

Solution

To resolve the issue:

1. Set the port security mode to autoLearn.

```
[Device-GigabitEthernet1/0/1] undo port-security port-mode
[Device-GigabitEthernet1/0/1] port-security max-mac-count 64
[Device-GigabitEthernet1/0/1] port-security port-mode autolearn
[Device-GigabitEthernet1/0/1] port-security mac-address security 1-1-2 vlan 1
```

2. If the issue persists, contact H3C Support.

Configuring user profiles

About user profiles

A user profile defines a set of parameters, such as a QoS policy, for a user or a class of users. A user profile can be reused when a user connected to the network on a different interface.

The user profile application allows flexible traffic policing on a per-user basis. Each time a user passes authentication, the server sends the device the name of the user profile specified for the user. The device applies the parameters in the user profile to the user.

User profiles are typically used for resource allocation per user. For example, the interface-based traffic policing limits the total amount of bandwidth available to a group of users. However, user-profile-based traffic policing can limit the amount of bandwidth available to a single user.

Prerequisites for user profile

A user profile works with authentication methods. You must configure authentication for a user profile. For information about supported authentication methods, see the configuration guides for the related authentication modules.

Configuring a user profile

1. Enter system view.
   system-view
2. Create a user profile and enter user profile view.
   user-profile *profile-name*
3. Apply an existing QoS policy to the user profile.
   qos apply policy *policy-name* { **inbound** | **outbound** }
   By default, no QoS policy is applied to a user profile.
   For information about QoS policies, see *ACL and QoS Configuration Guide*.

Display and maintenance commands for user profiles

Execute **display** commands in any view.

Task	Command
Display configuration and online user information for the specified user profile or all user profiles.	**display user-profile** [**name** *profile-name*] [**slot** *slot-number*]

User profile configuration examples

Example: Configuring user profiles and QoS policies

Network configuration

As shown in Figure 1, the device performs local 802.1X authentication on the users in domain **user** for authentication and authorization efficiency.

Configure user profiles and QoS policies on the device to meet the following requirements:

- User A cannot access the Internet during 8: 30 and 12:00 every day even if User A passes 802.1X authentication.
- User B has an upload speed of 2 Mbps after passing 802.1X authentication.
- User C has a download speed of 4 Mbps after passing 802.1X authentication.

Figure 1 Network diagram

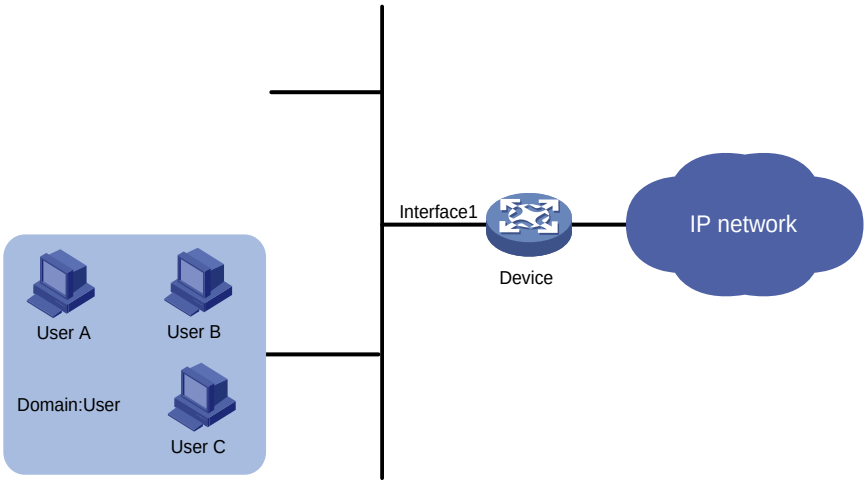

Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Configure a QoS policy for User A:

   # Create a periodic time range from 8:30 to 12:00 every day.

   ```
   <Device> system-view
   [Device] time-range for_usera 8:30 to 12:00 daily
   ```

   # Create IPv4 basic ACL 2000, and configure a rule to match all packets during the time range **for_usera**.

   ```
   [Device] acl basic 2000
   [Device-acl-basic-2000] rule permit time-range for_usera
   [Device-acl-basic-2000] quit
   ```

   # Create a traffic class named **for_usera**, and use ACL 2000 as the match criterion.

   ```
   [Device] traffic classifier for_usera
   [Device-classifier-for_usera] if-match acl 2000
   [Device-classifier-for_usera] quit
   ```

Create a traffic behavior named **for_usera**, and configure the deny action.

```
[Device] traffic behavior for_usera
[Device-behavior-for_usera] filter deny
[Device-behavior-for_usera] quit
```

Create a QoS policy named **for_usera**, and associate traffic class **for_usera** and traffic behavior **for_usera** in the QoS policy.

```
[Device] qos policy for_usera
[Device-qospolicy-for_usera] classifier for_usera behavior for_usera
[Device-qospolicy-for_usera] quit
```

2. Create a user profile for User A and apply the QoS policy to the user profile:

Create a user profile named **usera**.

```
[Device] user-profile usera
```

Apply QoS policy **for_usera** to the inbound direction of user profile **usera**.

```
[[Device-user-profile-usera] qos apply policy for_usera inbound
[Device-user-profile-usera] quit
```

3. Configure a QoS policy for limiting the traffic rate for User B:

Create a traffic class named **class** to match all packets.

```
[Device] traffic classifier class
[Device-classifier-class] if-match any
[Device-classifier-class] quit
```

Create a traffic behavior named **for_userb**, and configure a traffic policing action (CIR 2000 kbps).

```
[Device] traffic behavior for_userb
[Device-behavior-for_userb] car cir 2000
[Device-behavior-for_userb] quit
```

Create a QoS policy named **for_userb**, and associate traffic class **class** and traffic behavior **for_userb** in the QoS policy.

```
[Device] qos policy for_userb
[Device-qospolicy-for_userb] classifier class behavior for_userb
[Device-qospolicy-for_userb] quit
```

4. Create a user profile for User B and apply the QoS policy to the user profile:

Create a user profile named **userb**.

```
[Device] user-profile userb
```

Apply QoS policy **for_userb** to the inbound direction of user profile **userb**.

```
[Device-user-profile-userb] qos apply policy for_userb inbound
[Device-user-profile-userb] quit
```

5. Configure a QoS policy for limiting the traffic rate for User C:

Create a traffic behavior named **for_userc**, and configure a traffic policing action (CIR 4000 kbps).

```
[Device] traffic behavior for_userc
[Device-behavior-for_userc] car cir 4000
[Device-behavior-for_userc] quit
```

Create a QoS policy named **for_userc**, and associate traffic class **class** and traffic behavior **for_userc** in the QoS policy.

```
[Device] qos policy for_userc
[Device-qospolicy-for_userc] classifier class behavior for_userc
[Device-qospolicy-for_userc] quit
```

6. Create a user profile for User C and apply the QoS policy to the user profile:

Create a user profile named **userc**.

```
[Device] user-profile userc
```

Apply QoS policy **for_userc** to the outbound direction of user profile **userc**.

```
[Device-user-profile-userc] qos apply policy for_userc outbound
[Device-user-profile-userc] quit
```

7. Configure local users:

Create a local user named **usera**.

```
[Device] local-user usera class network
New local user added.
```

Set the password to **123456TESTusera&!** for user **usera**.

```
[Device-luser-network-usera] password simple 123456TESTusera&!
```

Authorize user **usera** to use the LAN access service.

```
[Device-luser-network-usera] service-type lan-access
```

Specify user profile **usera** as the authorization user profile for user **usera**.

```
[Device-luser-network-usera] authorization-attribute user-profile usera
[Device-luser-network-usera] quit
```

Create a local user named **userb**.

```
[Device] local-user userb class network
New local user added.
```

Set the password to **123456TESTuserb&!** for user **userb**.

```
[Device-luser-network-userb] password simple 123456TESTuserb&!
```

Authorize user **userb** to use the LAN access service.

```
[Device-luser-network-userb] service-type lan-access
```

Specify user profile **userb** as the authorization user profile for user **userb**.

```
[Device-luser-network-userb] authorization-attribute user-profile userb
[Device-luser-network-userb] quit
```

Create a local user named **userc**.

```
[Device] local-user userc class network
New local user added.
```

Set the password to **123456TESTuserc&!** for user **userc**.

```
[Device-luser-network-userc] password simple 123456TESTuserc&!
```

Authorize user **userc** to use the LAN access service.

```
[Device-luser-network-userc] service-type lan-access
```

Specify user profile **userc** as the authorization user profile for user **userc**.

```
[Device-luser-network-userc] authorization-attribute user-profile userc
[Device-luser-network-userc] quit
```

8. Configure the authentication, authorization, and accounting methods for local users:

```
[Device] domain user
[Device-isp-user] authentication lan-access local
[Device-isp-user] authorization lan-access local
[Device-isp-user] accounting login none
[Device-isp-user] quit
```

9. Configure 802.1X:

Enable 802.1X on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] dot1x
```

Enable MAC-based access control on the port. By default, a port uses MAC-based access control.

```
[Device-GigabitEthernet1/0/1] dot1x port-method macbased
[Device-GigabitEthernet1/0/1] quit
```

Enable 802.1X globally.

```
[Device] dot1x
```

Verifying the configuration

Verify that the three users can pass 802.1X authentication and that QoS policies take effect on these users. (Details not shown.)

Display user profile information.

```
<Device> display user-profile
  User-Profile: usera
    Inbound:
      Policy: for_usera

    slot 1:
      User -:
        Authentication type: 802.1X
        Network attributes:
          Interface    : GigabitEthernet1/0/1
          MAC address  : 6805-ca06-557b
          Service VLAN : 1

  User-Profile: userb
    Inbound:
      Policy: for_userb

    slot 1:
      User -:
        Authentication type: 802.1X
        Network attributes:
          Interface    : GigabitEthernet1/0/1
          MAC address  : 80c1-6ee0-2664
          Service VLAN : 1

  User-Profile: userc
    Outbound:
      Policy: for_userc

    slot 1:
      User -:
        Authentication type: 802.1X
        Network attributes:
          Interface    : GigabitEthernet1/0/1
          MAC address  : 6805-ca05-3efa
          Service VLAN : 1
```

Configuring password control

About password control

Password control allows you to implement the following features:

- Manage login and super password setup, expirations, and updates for local users.
- Control user login status based on predefined policies.

For more information about local users, see "Configuring AAA." For information about super passwords, see RBAC in *Fundamentals Configuration Guide*.

Password setting

Minimum password length

You can define the minimum length of user passwords. The system rejects the setting of a password that is shorter than the configured minimum length.

Password composition policy

A password can be a combination of characters from the following types:

- Uppercase letters A to Z.
- Lowercase letters a to z.
- Digits 0 to 9.
- Special characters in Table 1.

Table 1 Special Characters

Character name	Symbol	Character name	Symbol
Ampersand sign	&	Apostrophe	'
Asterisk	*	At sign	@
Back quote	`	Back slash	\
Blank space	N/A	Caret	^
Colon	:	Comma	,
Dollar sign	$	Dot	.
Equal sign	=	Exclamation point	!
Left angle bracket	<	Left brace	{
Left bracket	[	Left parenthesis	(
Minus sign	-	Percent sign	%
Plus sign	+	Pound sign	#
Quotation marks	"	Right angle bracket	>
Right brace	}	Right bracket	]
Right parenthesis	)	Semi-colon	;
Slash	/	Tilde	~

Character name	Symbol	Character name	Symbol
Underscore	_	Vertical bar	|

Depending on the system's security requirements, you can set the minimum number of character types a password must contain and the minimum number of characters for each type, as shown in Table 2.

Table 2 Password composition policy

Password combination level	Minimum number of character types	Minimum number of characters for each type
Level 1	One	One
Level 2	Two	One
Level 3	Three	One
Level 4	Four	One

When a user sets or changes a password, the system checks if the password meets the combination requirement. If it does not, the operation fails.

Password complexity checking policy

A less complicated password is more likely to be cracked, such as a password containing the username or repeated characters. For higher security, you can configure a password complexity checking policy to ensure that all user passwords are relatively complicated. When a user configures a password, the system checks the complexity of the password. If the password is complexity-incompliant, the configuration will fail.

You can apply the following password complexity requirements:

- A password cannot contain the username, the reverse of the username, or part of the username or the reverse of the username. For example, if the username is **abc**, a password such as **abc982**, **2cba**, **ab**, or **cb** is not complex enough.
- A password cannot contain three or more identical consecutive characters. For example, password **a111** is not complex enough.
- A password cannot contain multiple horizontally-adjacent characters on the keyboard. For example, if a password can contain only two horizontally-adjacent characters on the keyboard, **QWE12** and **EWQ21** do not meet the complexity requirements.

Password updating and expiration

Password updating

This feature allows you to set the minimum interval at which users can change their passwords. A user can only change the password once within the specified interval.

The minimum interval does not apply to the following situations:

- A user is prompted to change the password at first login.
- The password aging time expires.

Password expiration

Password expiration imposes a lifecycle on a user password. After the password expires, the user needs to change the password.

The system displays an error message for a login attempt with an expired password. The user is asked to provide a new password. The new password must be valid, and the user must enter exactly the same password when confirming it.

Telnet users, SSH users, and console users can change their own passwords. FTP users must have their passwords changed by the administrator.

Early notice on pending password expiration

When a user logs in, the system checks whether the password will expire in a time equal to or less than the specified notification period. If so, the system notifies the user when the password will expire and provides a choice for the user to change the password.

- If the user sets a new valid password, the system records the new password and the setup time.
- If the user does not or fails to change the password, the system allows the user to log in by using the current password until the password expires.

Telnet users, SSH users, and console users can change their own passwords. FTP users must have their passwords changed by the administrator.

Login with an expired password

You can allow a user to log in a certain number of times within a period of time after the password expires. For example, if you set the maximum number of logins with an expired password to 3 and the time period to 15 days, a user can log in three times within 15 days after the password expires.

Password history

This feature allows the system to store passwords that a user has used.

When a network access user changes the password, the system compares the new password with the current password and those stored in the password history records. The new password must be different from the current one and those stored in the history records by a minimum of four different characters. Otherwise, the system will display an error message, and the new password is not successfully set.

The local passwords and super passwords for device management users are stored in hash form and cannot be converted to plain texts. When a device management user changes a local password or super password, follow these rules:

- If the new password is set by using the hash method, the system will not compare the new password with the current one and those stored in the history password records.
- If the new password is set in plain text, the system compares the new password with the current password and those stored in the password history records. A new password must be different from those stored in the history password records. If the current password is required, the new password must also be different from the current one by a minimum of four different characters. Otherwise, the system will display an error message, and the new password is not successfully set.

You can set the maximum number of history password records for the system to maintain for each user. When the number of history password records exceeds the setting, the most recent record overwrites the earliest one.

Current login passwords are not stored in the password history for device management users. Device management users have their passwords saved in cipher text, which cannot be recovered to plaintext passwords.

User login control

First login

By default, if the global password control feature is enabled, users must change the password at first login before they can access the system. In this situation, password changes are not subject to the minimum password update interval. If it is not necessary for users to change the password at first login, disable the password change at first login feature.

Password control blacklist

The password control blacklist prevents abnormal users from logging in by recording the login failures and maintaining the status of blacklisted user accounts.

If an FTP or VTY user fails to log in, the system adds the user account and the user's IP address to the password control blacklist. If a console user fails to log in, the system adds the user account to the password control blacklist.

If a user uses the same user account to log in to the device from different IP addresses and fails the logins, the device will create a blacklist entry for each IP address for the user account. When the maximum number of blacklist entries for the user account is reached, a blacklist entry for a new IP address of the user account will overwrite the earliest blacklist entry for the user account.

Login attempt limit

Limiting the number of consecutive login failures can effectively prevent password guessing.

When the number of consecutive failed attempts reaches the maximum limit, login attempt limit limits the user in any of the following ways:

- For an FTP or VTY user, the system prohibits the user from using the user account to log in through the user's IP address. For a console user, the system prohibits the user from logging in through console user line. The locked user can use their own account to log in to the device only after the account is manually removed from the password control blacklist.
- Allows the user to continue using the user account. The user account is removed from the password control blacklist when the user uses this account to successfully log in to the device.
- Locks the user account and the user's IP address for a period of time.

  The user can use the account to log in when either of the following conditions exists:

  - The locking timer expires.
  - The account is manually removed from the password control blacklist before the locking timer expires.

NOTE:

This account is locked only for the user at the locked IP address. A user from an unlocked IP address can still use this account, and the user at the locked IP address can use other unlocked user accounts.

Maximum account idle time

You can set the maximum account idle time for user accounts. When an account is idle for this period of time since the last successful login, the account becomes invalid.

Login control with a weak password

The system checks for weak passwords for Telnet, SSH, HTTP, or HTTPS device management users. A password is weak if it does not meet the following requirements:

- Password composition restriction.
- Minimum password length restriction.
- Password complexity username checking policy.

By default, the system displays a message about a weak password but does not force the user to change it. To improve the device security, you can enable the mandatory weak password change feature, which forces the users to change the identified weak passwords. The users can log in to the device only after their passwords meet the password requirements.

Password not displayed in any form

For security purposes, nothing is displayed when a user enters a password.

Logging

The system generates a log each time a user changes its password successfully or is added to the password control blacklist because of login failures.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

Restrictions and guidelines: Password control configuration

IMPORTANT:

To successfully enable the global password control feature and allow device management users to log in to the device, make sure the device have sufficient storage space.

The password control features can be configured in several different views, and different views support different features. The settings configured in different views or for different objects have the following application ranges:

- Settings for super passwords apply only to super passwords.
- Settings in local user view apply only to the password of the local user.
- Settings in user group view apply to the passwords of the local users in the user group if you do not configure password policies for these users in local user view.
- Global settings in system view apply to the passwords of the local users in all user groups if you do not configure password policies for these users in both local user view and user group view.

For local user passwords, the settings with a smaller application scope have higher priority. The system prefers to use the non-default setting in local user view for a local user.

- If the default setting is configured for the local user, the system uses the non-default setting for the user group to which the local user belongs.
- If the default setting is configured for the user group, the system uses the global setting.

Password control tasks at a glance

To configure password control, perform the following tasks:

1. Enabling password control
2. (Optional.) Setting global password control parameters
3. (Optional.) Setting user group password control parameters
4. (Optional.) Setting local user password control parameters
5. (Optional.) Setting super password control parameters
6. (Optional.) Enabling SNMP notifications for password control

Enabling password control

About this task

For device management users, enabling global password control is a prerequisite for password control functions to take effect except for password composition policy, minimum password length, and username checking. For a specific password restriction setting (password expiration or password history management) to take effect, make sure you enable both the global password control feature and the specific password restriction.

For network access users, all password control functions take effect only after the global password control feature is enabled.

Restrictions and guidelines

After global password control is enabled, follow these restrictions and guidelines:

- You cannot display the password and super password configurations for device management users by using the corresponding **display** commands.
- You cannot display the password configuration for network access users by using the corresponding **display** command.
- The passwords configured for local users must contain a minimum of four different characters.
- In FIPS mode, the global password control feature is enabled for device management users and cannot be disabled for them.
- To ensure correct function of password control, configure the device to use NTP to obtain the UTC time. After global password control is enabled, password control will record the UTC time when the password is set. The recorded UTC time might not be consistent with the actual UTC time due to power failure or device reboot. The inconsistency will cause the password expiration feature to malfunction. For information about NTP, see *Network Management and Monitoring Configuration Guide*.
- The device automatically generates a .dat file and saves the file to the storage media. The file is used to record authentication and login information of the local users. Do not manually delete or modify the file.
- The global password control feature enables the system to record history passwords. When the number of history password records of a user reaches the maximum number, the newest history record overwrites the earliest one. To delete the existing history password records, use one of the following methods:
  - Use the **undo password-control enable** command to disable the password control feature globally.
  - Use the **reset password-control history-record** command to clear the passwords manually.

Procedure

1. Enter system view.

   system-view

2. Enable the global password control feature.

   In non-FIPS mode:

   password-control enable [**network-class**]

   By default, the global password control feature is disabled for device management and network access users.

   In FIPS mode:

   password-control enable [**network-class**]

By default, the global password control feature is enabled for device management users and cannot be disabled. The global password control feature is disabled for network access users.

3. (Optional.) Enable a password restriction feature.

   password-control { **aging** | **composition** | **history** | **length** } **enable**

   By default, all four password restriction features are enabled.

Setting global password control parameters

Restrictions and guidelines

The global password control parameters in system view apply to all device management and network access local users.

You can configure all password control features for device management users. The password aging time, minimum password length, password complexity policy, password composition policy, and user login attempt limit can be configured in system view, user group view, and local user view.

You can configure only the following password control features for network access users:

- Minimum password length.
- Password complexity policy.
- Password composition policy.
- Minimum password update interval.
- Maximum number of history password records for each user.

Where, the minimum password length, password complexity policy, and password composition policy can be configured in system view, user group view, and local user view.

The password settings with a smaller application scope have higher priority. For local users, password settings configured in local user view have the highest priority, and global settings in system view have the lowest priority.

The **password-control login-attempt** command takes effect immediately and can affect the users already in the password control blacklist. Other password control configurations do not take effect on users that have been logged in or passwords that have been configured.

Procedure

1. Enter system view.

   system-view

2. Configure password settings.
   - Set the minimum password length.

     In non-FIPS mode:

     password-control length *length*

     The default setting is 10 characters.

     In FIPS mode:

     password-control length *length*

     The default length is 15 characters.
   - Configure the password composition policy.

     In non-FIPS mode:

     password-control composition type-number *type-number* [**type-length** *type-length*]

     By default, a password must contain a minimum of two character types and a minimum of one character for each type.

In FIPS mode:

password-control composition type-number *type-number* [**type-length** *type-length*]

By default, a password must contain a minimum of four character types and a minimum of one character for each type.

- Configure the password complexity checking policy.

  password-control complexity { **adjacent-character** | **same-character** | **user-name** } **check**

  In non-FIPS mode:

  By default, username checking is enabled but repeated character checking and horizontally-adjacent character checking are disabled.

  In FIPS mode:

  By default, the system does not perform password complexity checking.

- Specify the maximum number of horizontally-adjacent characters on the keyboard that can be included in a password.

  password-control adjacent-character max-number *number*

  By default, a maximum of three horizontally-adjacent characters on the keyboard can be included in a password.

- Set the maximum number of history password records for each user.

  password-control history *max-record-number*

  The default setting is 4.

3. Configure password updating and expiration.

- Set the minimum password update interval.

  password-control update interval *interval*

  The default setting is 24 hours.

- Set the password aging time.

  password-control aging *aging-time*

  The default setting is 90 days.

- Set the number of days during which a user is notified of the pending password expiration.

  password-control alert-before-expire *alert-time*

  The default setting is 7 days.

- Set the maximum number of days and maximum number of times that a user can log in after the password expires.

  password-control expired-user-login delay *delay* **times** *times*

  By default, a user can log in three times within 30 days after the password expires.

4. Configure user login control.

- Enable the password control blacklist feature for all user line types.

  password-control blacklist all-line

  By default, the password control blacklist feature is disabled for all user line types. The password control blacklist feature is enabled only for FTP and VTY users when you enable the global password control feature.

- Add only usernames to the password control blacklist for users failing authentication.

  password-control blacklist user-info username-only

  By default, both usernames and IP addresses are added to the password control blacklist when the users fail authentication.

- Set the maximum number of blacklist entries for a user account.

password-control per-user blacklist-limit *max-number*

By default, the maximum number of blacklist entries for a user account is 32.

- Configure the login attempt limit.

  password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

  By default, the maximum number of login attempts is 3 and a user failing to log in after the specified number of attempts must wait for 1 minute before trying again.

- Set the maximum account idle time.

  password-control login idle-time *idle-time*

  The default setting is 90 days.

  If a user account is idle for this period of time, the account becomes invalid and can no longer be used to log in to the device. To disable the account idle time restriction, set the idle time value to 0.

- Set the user authentication timeout time.

  password-control authentication-timeout *timeout*

  The default setting is 600 seconds.

  This command takes effect only on Telnet and terminal users.

- Disable password change at first login.

  undo password-control change-password first-login enable

  By default, the password change at first login feature is enabled.

  In FIPS mode, the password change at first login feature cannot be disabled.

- Enable mandatory weak password change.

  password-control change-password weak-password enable

  In non-FIPS mode:

  By default, the mandatory weak password change feature is disabled.

  In FIPS mode:

  By default, the mandatory weak password change feature is enabled, and cannot be disabled.

Setting user group password control parameters

1. Enter system view.

   system-view

2. Create a user group and enter its view.

   user-group *group-name*

   For information about how to configure a user group, see "Configuring AAA."

3. Configure the password aging time for the user group.

   password-control aging *aging-time*

   By default, the password aging time of the user group equals the global password aging time.

4. Configure the minimum password length for the user group.

   password-control length *length*

   By default, the minimum password length of the user group equals the global minimum password length.

5. Configure the password composition policy for the user group.

password-control composition type-number *type-number* [**type-length** *type-length*]

By default, the password composition policy of the user group equals the global password composition policy.

6. Configure the password complexity checking policy for the user group.

   password-control complexity { **adjacent-character** | **same-character** | **user-name** } **check**

   By default, the password complexity checking policy of the user group equals the global password complexity checking policy.

7. Configure the login attempt limit.

   password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

   By default, the login-attempt policy of the user group equals the global login-attempt policy.

Setting local user password control parameters

1. Enter system view.

   system-view

2. Create a device management or network access user and enter its view.
   - Create a device management user and enter its view.

     local-user *user-name* **class manage**
   - Create a network access user and enter its view.

     local-user *user-name* **class network**

   By default, no local user exists.

   For information about local user configuration, see "Configuring AAA."

3. Configure the password aging time for the local user.

   password-control aging *aging-time*

   By default, the setting equals that for the user group to which the local user belongs. If no aging time is configured for the user group, the global setting applies to the local user.

   This command is available only for device management users.

4. Configure the minimum password length for the local user.

   password-control length *length*

   By default, the setting equals that for the user group to which the local user belongs. If no minimum password length is configured for the user group, the global setting applies to the local user.

5. Configure the password composition policy for the local user.

   password-control composition type-number *type-number* [**type-length** *type-length*]

   By default, the settings equal those for the user group to which the local user belongs. If no password composition policy is configured for the user group, the global settings apply to the local user.

6. Configure the password complexity checking policy for the local user.

   password-control complexity { **adjacent-character** | **same-character** | **user-name** } **check**

   By default, the settings equal those for the user group to which the local user belongs. If no password complexity checking policy is configured for the user group, the global settings apply to the local user.

7. Configure the login attempt limit.

   password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

   By default, the settings equal those for the user group to which the local user belongs. If no login-attempt policy is configured for the user group, the global settings apply to the local user.

   This command is available only for device management users.

Setting super password control parameters

1. Enter system view.

   system-view

2. Set the password aging time for super passwords.

   password-control super aging *aging-time*

   The default setting is 90 days.

3. Configure the minimum length for super passwords.

   In non-FIPS mode:

   password-control super length *length*

   The default setting is 10 characters.

   In FIPS mode:

   password-control super length *length*

   The default setting is 15 characters.

4. Configure the password composition policy for super passwords.

   In non-FIPS mode:

   password-control super composition type-number *type-number* [**type-length** *type-length*]

   By default, a super password must contain a minimum of two character types and a minimum of one character for each type.

   In FIPS mode:

   password-control super composition type-number *type-number* [**type-length** *type-length*]

   By default, a super password must contain a minimum of four character types and a minimum of one character for each type.

5. Configure the super password complexity checking policy.

   password-control super complexity { **adjacent-character** | **same-character** } **check**

   By default, the system does not perform password complexity checking on super passwords. That is, a super password can contain consecutive identical characters and horizontally-adjacent characters on the keyboard.

6. Specify the maximum number of horizontally-adjacent characters on the keyboard that can be included in a super password.

   password-control super adjacent-character max-number *number*

   By default, a maximum of three horizontally-adjacent characters on the keyboard can be included in a super password.

Enabling SNMP notifications for password control

About this task

Password control supports the following SNMP notifications:

- **convert-format-failed**: Sends SNMP notifications when converting memory data to file storage fails before writing user password records to the password record file.
- **copy-file-failed**: Sends SNMP notifications when the password records failed to be copied to the record file on the subordinate device.
- **notify-write-file-failed**: Sends SNMP notifications when a request message to write user passwords to the password record file failed to be issued.
- **open-file-failed**: Sends SNMP notifications when a .dat file failed to be created or opened due to a file system error.
- **space-not-enough**: Sends SNMP notifications when the space of the storage medium (flash or CF card) where a .dat file is saved is insufficient.
- **write-password-failed**: Sends SNMP notifications when user passwords failed to be written to the password record file.

If you enable SNMP notifications for the password control module, the module will generate notifications to report key events on the module. The generated notifications will be sent to the SNMP module on the device. You can configure SNMP notification settings as needed.

For more information about notifications, see SNMP configuration in Network Management and Monitoring Configuration Guide.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for password control.

   snmp-agent trap enable password-control [**convert-format-failed** | **copy-file-failed** | **notify-write-file-failed** | **open-file-failed** | **space-not-enough** | **write-password-failed**] *

   By default, SNMP notifications are disabled for password control.

Display and maintenance commands for password control

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display password control configuration.	**display password-control** [**super**]
Display information about users in the password control blacklist.	**display password-control blacklist** [**user-name** *user-name* | **ip** *ipv4-address* | **ipv6** *ipv6-address*]
Delete users from the password control blacklist.	**reset password-control blacklist** [**user-name** *user-name*]
Clear history password records.	**reset password-control history-record** [**user-name** *user-name* | **super** [**role**

	role-name] | **network-class** [**user-name** *user-name*]]

Password control configuration examples

Example: Configuring password control

Network configuration

Configure a global password control policy to meet the following requirements:

- A password must contain a minimum of 16 characters.
- A password must contain a minimum of four character types and a minimum of four characters for each type.
- An FTP or VTY user failing to provide the correct password in two successive login attempts is permanently prohibited from logging in with the current IP address.
- A user can log in five times within 60 days after the password expires.
- A password expires after 30 days.
- The minimum password update interval is 36 hours.
- The maximum account idle time is 30 days.
- A password cannot contain the username or the reverse of the username, or part of the username or the reverse of the username.
- A password cannot contain three or more identical consecutive characters.
- A password cannot contain more than four horizontally-adjacent characters on the keyboard.

Configure a super password control policy for user role **network-operator** to meet the following requirements:

- A super password must contain a minimum of 24 characters.
- A super password must contain a minimum of four character types and a minimum of five characters for each type.
- A super password cannot contain more than four horizontally-adjacent characters on the keyboard.

Configure a password control policy for local Telnet user **test** to meet the following requirements:

- The password must contain a minimum of 24 characters.
- The password must contain a minimum of four character types and a minimum of five characters for each type.
- The password for the local user expires after 20 days.

Procedure

Enable the password control feature globally.

```
<Sysname> system-view
[Sysname] password-control enable
```

Allow a maximum of two consecutive login failures on a user account, and lock the user account and the user's IP address permanently if the limit is reached.

```
[Sysname] password-control login-attempt 2 exceed lock
```

Set all passwords to expire after 30 days.

```
[Sysname] password-control aging 30
```

Globally set the minimum password length to 16 characters.

```
[Sysname] password-control length 16
```

Set the minimum password update interval to 36 hours.

```
[Sysname] password-control update-interval 36
```

Specify that a user can log in five times within 60 days after the password expires.

```
[Sysname] password-control expired-user-login delay 60 times 5
```

Set the maximum account idle time to 30 days.

```
[Sysname] password-control login idle-time 30
```

Enable username checking.

```
[Sysname] password-control complexity user-name check
```

Enable repeated character checking.

```
[Sysname] password-control complexity same-character check
```

Enable horizontally-adjacent character checking in the password complexity checking policy.

```
[Sysname] password-control complexity adjacent-character check
```

Refuse a password that contains more than four horizontally-adjacent characters on the keyboard.

```
[Sysname] password-control adjacent-character max-number 4
```

Globally specify that all passwords must each contain a minimum of four character types and a minimum of four characters for each type.

```
[Sysname] password-control composition type-number 4 type-length 4
```

Set the minimum super password length to 24 characters.

```
[Sysname] password-control super length 24
```

Specify that a super password must contain a minimum of four character types and a minimum of five characters for each type.

```
[Sysname] password-control super composition type-number 4 type-length 5
```

Enable horizontally-adjacent character checking in the super password complexity checking policy.

```
[Sysname] password-control super complexity adjacent-character check
```

Refuse a super password that contains more than four horizontally-adjacent characters on the keyboard.

```
[Sysname] password-control super adjacent-character max-number 4
```

Configure a super password used for switching to user role **network-operator** as **123456789ABGFTweuix@#$%!** in plain text.

```
[Sysname] super password role network-operator simple 123456789ABGFTweuix@#$%!
```

Create a device management user named **test**.

```
[Sysname] local-user test class manage
```

Set the service type of the user to **Telnet**.

```
[Sysname-luser-manage-test] service-type telnet
```

Set the minimum password length to 24 for the local user.

```
[Sysname-luser-manage-test] password-control length 24
```

Specify that the password of the local user must contain a minimum of four character types and a minimum of five characters for each type.

```
[Sysname-luser-manage-test] password-control composition type-number 4 type-length 5
```

Set the password for the local user to expire after 20 days.

```
[Sysname-luser-manage-test] password-control aging 20
```

Configure the password of the local user in interactive mode.

```
[Sysname-luser-manage-test] password
```

```
Password:
Confirm :
Updating user information. Please wait ... ...
[Sysname-luser-manage-test] quit
```

Verifying the configuration

Display the global password control configuration.

```
<Sysname> display password-control
 Global password control configurations:
 Password control:                    Enabled(device management users)
                                      Disabled (network access users)
 Password aging:                      Enabled (30 days)
 Password length:                     Enabled (16 characters)
 Password composition:                Enabled (4 types, 4 characters per type)
 Password history:                    Enabled (max history record:4)
 Early notice on password expiration:  7 days
 User authentication timeout:         600 seconds
 Maximum login attempts:              2
 Action for exceeding login attempts:  Lock
 Minimum interval between two updates: 36 hours
 User account idle time:              30 days
 Logins with aged password:           5 times in 60 days
 Password complexity:                 Enabled (username checking)
                                      Enabled (repeated characters checking)
 Password change:                     Enabled (first login)
                                      Disabled (mandatory weak password change)
                                      Enabled (max adjacent characters:4)
 All line:                            Disabled (all line blacklist)
```

Display the password control configuration for super passwords.

```
<Sysname> display password-control super
 Super password control configurations:
 Password aging:                      Enabled (90 days)
 Password length:                     Enabled (24 characters)
 Password composition:                Enabled (4 types, 5 characters per type)
Password complexity:                 Disabled (repeated characters checking)
                                      Enabled (max adjacent characters:4)
```

Display the password control configuration for local user **test**.

```
<Sysname> display local-user user-name test class manage
Total 1 local users matched.

Device management user test:
  State:                     Active
  Service type:              Telnet
  User group:                system
  Bind attributes:
  Authorization attributes:
    Work directory:          flash:
```

```
  User role list:          network-operator
Password control configurations:
  Password aging:          20 days
  Password length:         24 characters
  Password composition:    4 types, 5 characters per type
  Password complexity:     username checking
```

Example: Configuring keychains 2

Configuring keychains

About keychains

A keychain, a sequence of keys, provides dynamic authentication to ensure secure communication by periodically changing the key and authentication algorithm without service interruption.

A keychain operates in absolute time mode. In this mode, each time point during a key's lifetime is the UTC time and is not affected by the system's time zone or daylight saving time.

Each key in a keychain has a key string, authentication algorithm, sending lifetime, and receiving lifetime. When the system time is within the lifetime of a key in a keychain, an application uses the key to authenticate incoming and outgoing packets. The keys in the keychain take effect one by one according to the sequence of the configured lifetimes. In this way, the authentication algorithms and keys are dynamically changed to implement dynamic authentication.

Restrictions and guidelines: Keychain configuration

To make sure only one key in a keychain is used at a time to authenticate packets to a peer, set non-overlapping sending lifetimes for the keys in the keychain.

The keys used by the local device and the peer device must have the same authentication algorithm and key string.

Configuring a keychain

1. Enter system view.

   system-view

2. Create a keychain and enter keychain view.

   keychain *keychain-name* **mode absolute**

3. (Optional.) Configure TCP authentication.
   - Set the kind value in the TCP Enhanced Authentication Option.

     tcp-kind *kind-value*

     By default, the kind value is 254.
   - Set an algorithm ID for a TCP authentication algorithm.

     tcp-algorithm-id { **hmac-md5** | **hmac-sha-256** | **hamc-sm3** | **md5** | **sm3** } *algorithm-id*

     By default, the algorithm ID is 3 for the MD5 authentication algorithm, 51 for the SM3 authentication algorithm, 52 for the HMAC-SM3 authentication algorithm, 7 for the HMAC-SHA-256 authentication algorithm, and 5 for the HMAC-MD5 authentication algorithm.

   When the local device uses TCP to communicate with a peer device from another vendor, make sure both devices have the same kind value and algorithm ID settings. If they do not, modify the settings on the local device.

4. (Optional.) Set a tolerance time for accept keys in the keychain.

   accept-tolerance { *value* | **infinite** }

   By default, no tolerance time is configured for accept keys in a keychain.

If authentication information is changed, information mismatch occurs on the local and peer devices, and the service might be interrupted. Use this command to ensure continuous packet authentication.

5. Create a key and enter key view.

   key *key-id*

6. Configure the key.

   - Specify an authentication algorithm for the key.

     authentication-algorithm { **aes-128-cmac** | **aes-256-cmac** | **hmac-md5** | **hmac-sha-256** | **hmac-sm3** | **md5** | **sm3** }

     By default, no authentication algorithm is specified for a key.

   - Configure a key string for the key.

     key-string { **cipher** | **plain** } *string*

     By default, no key string is configured.

   - Set the sending lifetime in UTC mode for the key.

     send-lifetime utc *start-time start-date* { **duration** { *duration-value* | **infinite** } | **to** *end-time end-date* }

     By default, the sending lifetime is not configured for a key.

   - Set the receiving lifetime in UTC mode for the key.

     accept-lifetime utc *start-time start-date* { **duration** { *duration-value* | **infinite** } | **to** *end-time end-date* }

     By default, the receiving lifetime is not configured for a key.

   - (Optional.) Specify the key as the default send key.

     default-send-key

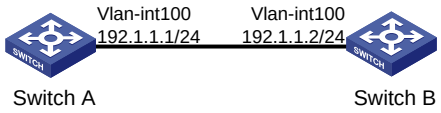
     By default, no default send key is configured for a keychain.

     You can specify only one key as the default send key in a keychain.

Display and maintenance commands for keychain

Execute **display** commands in any view.

Task	Command
Display keychain information.	**display keychain** [**name** *keychain-name* [**key** *key-id*]]



Keychain configuration example

Example: Configuring keychains

Network configuration

As shown in Figure 1, establish an OSPF neighbor relationship between Switch A and Switch B, and use a keychain to authenticate packets between the switches. Configure key 1 and key 2 for the keychain and make sure key 2 is used immediately when key 1 expires.

Figure 1 Network diagram

Procedure

1. Configure Switch A:

Configure IP addresses for interfaces. (Details not shown.)

Configure OSPF.

```
<SwitchA> system-view
[SwitchA] ospf 1 router-id 1.1.1.1
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 192.1.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
[SwitchA-ospf-1] quit
```

Create a keychain named **abc**, and specify the absolute time mode for it.

```
[SwitchA] keychain abc mode absolute
```

Create key **1** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[SwitchA-keychain-abc] key 1
[SwitchA-keychain-abc-key-1] authentication-algorithm md5
[SwitchA-keychain-abc-key-1] key-string plain 123456
[SwitchA-keychain-abc-key-1] send-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[SwitchA-keychain-abc-key-1] accept-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[SwitchA-keychain-abc-key-1] quit
```

Create key **2** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[SwitchA-keychain-abc] key 2
[SwitchA-keychain-abc-key-2] authentication-algorithm hmac-md5
[SwitchA-keychain-abc-key-2] key-string plain pwd123
[SwitchA-keychain-abc-key-2] send-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[SwitchA-keychain-abc-key-2] accept-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[SwitchA-keychain-abc-key-2] quit
[SwitchA-keychain-abc] quit
```

Configure VLAN-interface 100 to use keychain **abc** for authentication.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ospf authentication-mode keychain abc
[SwitchA-Vlan-interface100] quit
```

2. Configure Switch B:

Configure IP addresses for interfaces. (Details not shown.)

Configure OSPF.

```
[SwitchB] ospf 1 router-id 2.2.2.2
[SwitchB-ospf-1] area 0
```

```
[SwitchB-ospf-1-area-0.0.0.0] network 192.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

Create a keychain named **abc**, and specify the absolute time mode for it.

```
[SwitchB] keychain abc mode absolute
```

Create key **1** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[SwitchB-keychain-abc] key 1
[SwitchB-keychain-abc-key-1] authentication-algorithm md5
[SwitchB-keychain-abc-key-1] key-string plain 123456
[SwitchB-keychain-abc-key-1] send-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[SwitchB-keychain-abc-key-1] accept-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[SwitchB-keychain-abc-key-1] quit
```

Create key **2** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[SwitchB-keychain-abc] key 2
[SwitchB-keychain-abc-key-2] authentication-algorithm hmac-md5
[SwitchB-keychain-abc-key-2] key-string plain pwd123
[SwitchB-keychain-abc-key-2] send-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[SwitchB-keychain-abc-key-2] accept-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[SwitchB-keychain-abc-key-2] quit
[SwitchB-keychain-abc] quit
```

Configure VLAN-interface 100 to use keychain **abc** for authentication.

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ospf authentication-mode keychain abc
[SwitchB-Vlan-interface100] quit
```

Verifying the configuration

1. When the system time is within the lifetime from 10:00:00 to 11:00:00 on the day 2015/02/06, verify the status of the keys in keychain **abc**.

   # Display keychain information on Switch A. The output shows that key 1 is the valid key.

```
[SwitchA] display keychain

 Keychain name          : abc
   Mode                 : absolute
   Accept tolerance     : 0
   TCP kind value       : 254
   TCP algorithm value
     HMAC-MD5           : 5
     HMAC-SHA-256       : 7
     MD5                : 3
     HMAC-SM3           : 52
     SM3                : 51
   Default send key ID  : None
   Active send key ID   : 1
```

```
  Active accept key IDs: 1

  Key ID              : 1
    Key string        : $c$3$dYTC8QeOKJkwFwP2k/rWL+1p6uMTw3MqNg==
    Algorithm         : md5
    Send lifetime     : 10:00:00 2015/02/06 to 11:00:00 2015/02/06
    Send status       : Active
    Accept lifetime   : 10:00:00 2015/02/06 to 11:00:00 2015/02/06
    Accept status     : Active

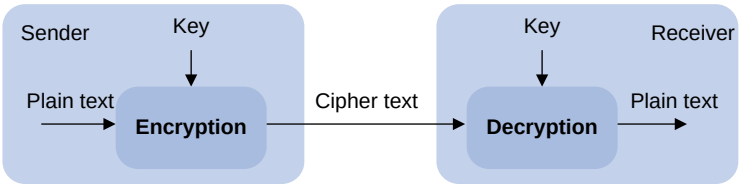
Managing public keys

About public key management



This chapter describes public key management for the following asymmetric key algorithms:

- Revest-Shamir-Adleman Algorithm (RSA).
- Digital Signature Algorithm (DSA).
- Elliptic Curve Digital Signature Algorithm (ECDSA).
- SM2 algorithm.

Asymmetric key algorithm overview

Asymmetric key algorithms are used by security applications to secure communications between two parties, as shown in Figure 1. Asymmetric key algorithms use two separate keys (one public and one private) for encryption and decryption. Symmetric key algorithms use only one key.

Figure 1 Encryption and decryption

A key owner can distribute the public key in plain text on the network but must keep the private key in privacy. It is mathematically infeasible to calculate the private key even if an attacker knows the algorithm and the public key.

The following asymmetric key algorithms are supported:

- Revest-Shamir-Adleman Algorithm (RSA).
- Digital Signature Algorithm (DSA).
- Elliptic Curve Digital Signature Algorithm (ECDSA).

Usage of asymmetric key algorithms

Security applications (such as SSH, SSL, and PKI) use the asymmetric key algorithms for the following purposes:

- **Encryption and decryption**—Any public key receiver can use the public key to encrypt information, but only the private key owner can decrypt the information.
- **Digital signature**—The key owner uses the private key to digitally sign information to be sent. The receiver decrypts the information with the sender's public key to verify information authenticity.

RSA, DSA, and ECDSA can all perform digital signature, but only RSA can perform encryption and decryption.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

Public key management tasks at a glance

To manage public keys, perform the following tasks:

1. Creating a local key pair
2. Distributing a local host public key

   Choose one of the following tasks:

   - Exporting a host public key
   - Displaying a host public key

   To enable the peer device to authenticate the local device, you must distribute the local device's public key to the peer device.
3. Configuring a peer host public key

   Choose one of the following tasks:

   - Importing a peer host public key from a public key file
   - Entering a peer host public key

   To encrypt information sent to a peer device or authenticate the digital signature of the peer device, you must configure the peer device's public key on the local device.
4. (Optional.) Destroying a local key pair
5. (Optional.) Configuring master keys

Creating a local key pair

Restrictions and guidelines

When you create a local key pair, follow these guidelines:

- The key algorithm must be the same as required by the security application.
- When you create an RSA or DSA key pair, enter an appropriate key modulus length at the prompt. The longer the key modulus length, the higher the security, and the longer the key generation time.

  When you create an ECDSA key pair, choose the appropriate elliptic curve. The elliptic curve determines the ECDSA key length. The longer the key length, the higher the security, and the longer the key generation time.

  See Table 1 for more information about key modulus lengths and key lengths.
- If you do not assign the key pair a name, the system assigns the default name to the key pair and marks the key pair as **default**. You can also assign the default name to another key pair, but the system does not mark the key pair as **default**. The key pair name must be unique among all manually named key pairs that use the same key algorithm. If a name conflict occurs, the system asks whether you want to overwrite the existing key pair.
- The key pairs are automatically saved and can survive system reboots.

Table 1 A comparison of different types of asymmetric key algorithms

Type	Generated key pairs	Modulus/key length
RSA	• In non-FIPS mode: ○ One host key pair, if you specify a key pair name. ○ One server key pair and one host key pair, if you do not specify a key pair name. Both key pairs use their default names. • In FIPS mode: One host key pair. **NOTE:** Only SSH 1.5 uses the RSA server key pair.	RSA key modulus length: • In non-FIPS mode: 512 to 4096 bits, 1024 bits by default. To ensure security, use a minimum of 768 bits. • In FIPS mode: A multiple of 256 bits in the range of 2048 to 4096 bits, 2048 bits by default.
DSA	One host key pair.	DSA key modulus length: • In non-FIPS mode: 512 to 2048 bits, 1024 bits by default. To ensure security, use a minimum of 768 bits. • In FIPS mode: The device does not support generating DSA host key pairs.
ECDSA	One host key pair.	ECDSA key length: • In non-FIPS mode: 192, 256, 384, or 521 bits. • In FIPS mode: 256, 384, or 521 bits.

Procedure

1. Enter system view.

   system-view

2. Create a local key pair.

   In non-FIPS mode:

   public-key local create { **dsa** | **ecdsa** [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**] | **rsa** } [**name** *key-name*]

   In FIPS mode:

   public-key local create { **ecdsa** [**secp256r1** | **secp384r1** | **secp521r1**] | **rsa** } [**name** *key-name*]

   By default, no local key pairs exist.

Distributing a local host public key

About distribution of local host public keys

You must distribute a local host public key to a peer device so the peer device can perform the following operations:

- Use the public key to encrypt information sent to the local device.
- Authenticate the digital signature signed by the local device.

To distribute a local host public key, you must first export or display the key.

- Export a host public key:
  - Export a host public key to a file.

- Export a host public key to the monitor screen, and then save it to a file.

  After the key is exported to a file, transfer the file to the peer device. On the peer device, import the key from the file.

- Display a host public key.

  After the key is displayed, record the key, for example, copy it to an unformatted file. On the peer device, you must literally enter the key.

Exporting a host public key

Restrictions and guidelines

When you export a host public key, follow these restrictions and guidelines:

- If you specify a file name in the command, the command exports the key to the specified file.
- If you do not specify a file name, the command exports the key to the monitor screen. You must manually save the exported key to a file.

Procedure

1. Enter system view.

   system-view

2. Export a local host public key.
   - Export an RSA host public key:

     In non-FIPS mode:

     public-key local export rsa [**name** *key-name*] { **openssh** | **ssh1** | **ssh2** } [*filename*]

     In FIPS mode:

     public-key local export rsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]
   - Export an ECDSA host public key.

     public-key local export ecdsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]
   - Export a DSA host public key.

     public-key local export dsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]

     This command is supported only in non-FIPS mode.

Displaying a host public key

Perform the following tasks in any view:

- Display local RSA public keys.

  display public-key local rsa public [**name** *key-name*]

  Do not distribute the RSA server public key **serverkey (default)** to a peer device.

- Display local ECDSA public keys.

  display public-key local ecdsa public [**name** *key-name*]

- Display local DSA public keys.

  display public-key local dsa public [**name** *key-name*]

Configuring a peer host public key

About peer host public key configuration

To encrypt information sent to a peer device or authenticate the digital signature of the peer device, you must configure the peer device's public key on the local device.

You can configure the peer host public key by using the following methods:

- Import the peer host public key from a public key file (recommended).
- Manually enter (type or copy) the peer host public key.

For information about how to obtain the host public key of a device, see "Distributing a local host public key."

Restrictions and guidelines for peer host public key configuration

When you configure a peer host public key, follow these restrictions and guidelines:

- When you manually enter the peer host public key, make sure the entered key is in the correct format. To obtain the peer host public key in the correct format, use the **display public-key local public** command to display the public key on the peer device and record the key. The format of the public key displayed in any other way might be incorrect. If the key is not in the correct format, the system discards the key and displays an error message.
- Always import rather than enter the peer host public key if you are not sure whether the device supports the format of the recorded peer host public key.

Importing a peer host public key from a public key file

About this task

Before you perform this task, make sure you have exported the host public key to a file on the peer device and obtained the file from the peer device. For information about exporting a host public key, see "Exporting a host public key."

After you import the key, the system automatically converts the imported public key to a string in the Public Key Cryptography Standards (PKCS) format.

Procedure

1. Enter system view.

   system-view

2. Import a peer host public key from a public key file.

   public-key peer *keyname* **import sshkey** *filename*

   By default, no peer host public keys exist.

Entering a peer host public key

About this task

Before you perform this task, make sure you have displayed the key on the peer device and recorded the key. For information about displaying a host public key, see "Displaying a host public key."

Procedure

1. Enter system view.
   system-view
2. Specify a name for the peer host public key and enter public key view.
   public-key peer *keyname*
3. Type or copy the key.
   You can use spaces and carriage returns, but the system does not save them.
4. Exit public key view.
   peer-public-key end
   When you exit public key view, the system automatically saves the peer host public key.

Destroying a local key pair

About this task

To ensure security, destroy the local key pair and generate a new key pair in any of the following situations:

- The local key has leaked. An intrusion event might occur.
- The storage media of the device is replaced.
- The local certificate has expired. For more information about local certificates, see "Configuring PKI."

Procedure

1. Enter system view.
   system-view
2. Destroy a local key pair.
   In non-FIPS mode:
   public-key local destroy { **dsa** | **ecdsa** | **rsa** } [**name** *key-name*]
   In FIPS mode:
   public-key local destroy { **ecdsa** | **rsa** } [**name** *key-name*]

Configuring master keys

Setting a master key

About this task

By default, a device uses the unified default master key to encrypt the key strings configured for each service module on the device. After you load the exported configuration file of a device on another device, you can use the default master key to decrypt and obtain the configured key strings. In this way, keys can be copied between devices, bringing security risks.

To improve the security and reliability of data, you can set a master key for the device. After you configure this feature on the device, you need to configure the relevant settings as prompted:

1. Validate your identity:
   - If the login authentication mode is **password** or **scheme**, the CLI prompts you to enter your password for login. After you pass the authentication, you go to step 2.

- If the login authentication mode is **none**, you do not need to perform identity authentication but go to step 2 directly.

  For more information about login authentication modes, see login management in *Fundamentals Configuration Guide*.

2. Select whether to enter the master key:
   - If you enter **N** or **n**, the device will automatically and randomly generate a master key.
   - If you enter **Y** or **y**, manually enter the prepared master key and confirm it.

The device stores the master key in the hard disk. Power-off or reboot of the device will not affect the set master key. The device uses the master key to encrypt the key strings configured for each service module on the device.

You can only use the **display master-key type** command to view the type of the master key. You cannot view or obtain the value of the master key by any means. This prevents copying the keys on the device to another device.

Restrictions and guidelines

When the storage space for master keys is insufficient, the device prompts whether to overwrite the oldest master key.

When the login authentication mode is **password** or **scheme**, you will be logged off after three consecutive authentication failures and thus cannot perform master key-related operations.

The minimum interval between setting master keys is 3 minutes.

Prerequisites

To manually enter a master key, prepare the master key and keep it safe before configuring this feature.

Procedure

1. Enter system view.
   system-view
2. Set a master key.
   set master-key

Clearing master keys

About this task

You can configure this feature to clear master keys in the following situations:

- You do not need to use the master key feature.
- The storage space for master keys is insufficient, and you want to clear existing master keys to release storage space.

The default master key of the device uses the fixed factory default value. With the **clear master-key** command executed, all set master keys will be cleared and the default fixed master key will be restored.

Procedure

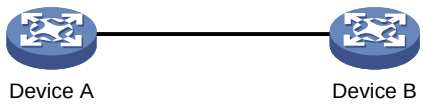
1. Enter system view.
   system-view
2. Clear master keys.
   clear master-key

Display and maintenance commands for public keys

Execute **display** commands in any view.

Task	Command
Display local public keys.	In non-FIPS mode: **display public-key local** { **dsa** | **ecdsa** | **rsa** } **public** [**name** *key-name*] In FIPS mode: **display public-key local** { **ecdsa** | **rsa** } **public** [**name** *key-name*]
Display peer host public keys.	**display public-key peer** [**brief** | **name** *publickey-name*]
Display the type of the current master key.	**display master-key type**

Examples of public key management



Example: Entering a peer host public key

Network configuration

As shown in Figure 2, to prevent illegal access, Device B authenticates Device A through a digital signature. Before configuring authentication parameters on Device B, use the following procedure to configure the public key of Device A on Device B:

- Create RSA key pairs on Device A and display the public keys of the RSA key pairs.
- Manually specify the RSA host public key of Device A on Device B.

Figure 2 Network diagram

Procedure

1. Configure Device A:

   # Create local RSA key pairs with the default names on Device A, and use the default key modulus length (1024 bits).

```
<DeviceA> system-view
[DeviceA] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
...
```

```
Create the key pair successfully.
```

Display all local RSA public keys.

```
[DeviceA] display public-key local rsa public

Example: Importing a public key from a public key file

Network configuration

As shown in Figure 3, Device B authenticates Device A through a digital signature. Before configuring authentication parameters on Device B, use the following procedure to configure the public key of Device A on Device B:

- Create RSA key pairs on Device A and export the RSA host public key to a file.
- Import the RSA host public key of Device A from the public key file to Device B.

Figure 3 Network diagram

Procedure

1. Configure Device A:

   # Create local RSA key pairs with the default names on Device A, and use the default key modulus length (1024 bits).

```
<DeviceA> system-view
[DeviceA] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...

[DeviceA] public-key local export rsa ssh2 devicea.pub
```

Enable the FTP server, create an FTP user with username **ftp** and password **123456TESTplat&!**, and configure the FTP user role as **network-admin**.

```
[DeviceA] ftp server enable
[DeviceA] local-user ftp
[DeviceA-luser-manage-ftp] password simple 123456TESTplat&!
[DeviceA-luser-manage-ftp] service-type ftp
[DeviceA-luser-manage-ftp] authorization-attribute user-role network-admin
[DeviceA-luser-manage-ftp] quit
```

2. Configure Device B:

Use FTP in binary mode to get public key file **devicea.pub** from Device A.

```
<DeviceB> ftp 10.1.1.1
Connected to 10.1.1.1 (10.1.1.1).
220 FTP service ready.
User(10.1.1.1:(none)):ftp
331 Password required for ftp.
Password:
230 User logged in.
Remote system type is UNIX.
Using binary mode to transfer files.
ftp> binary
200 TYPE is now 8-bit binary
ftp> get devicea.pub
227 Entering Passive Mode (10,1,1,1,118,252)
150 Accepted data connection
226 File successfully transferred
301 bytes received in 0.003 seconds (98.0 kbyte/s)
ftp> quit
221-Goodbye. You uploaded 0 and downloaded 1 kbytes.
221 Logout.
```

Import the host public key from key file **devicea.pub**.

```
<DeviceB> system-view
```

```
[DeviceB] public-key peer devicea import sshkey devicea.pub
```

Verifying the configuration

Verify that the peer host public key configured on Device B is the same as the key displayed on Device A.

```
[DeviceB] display public-key peer name devicea

=============================================
Key name: devicea
Key type: RSA
Key length: 1024
Key code:
   30819F300D06092A864886F70D010101050003818D003081890281810 0DA3B90F59237347B

Configuring PKI

About PKI

Public Key Infrastructure (PKI) is an asymmetric key infrastructure to encrypt and decrypt data for securing network services.

PKI uses digital certificates to distribute and employ public keys, and provides network communication and e-commerce with security services such as user authentication, data confidentiality, and data integrity. For more information about public keys, see "Managing public keys."

PKI terminology

Digital certificate

A digital certificate is an electronic document signed by a CA that binds a public key with the identity of its owner.

A digital certificate includes the following information:

- Issuer name (name of the CA that issued the certificate).
- Subject name (name of the individual or group to which the certificate is issued).
- Identity information of the subject.
- Subject's public key.
- Signature of the CA.
- Validity period.

A digital certificate must comply with the international standards of ITU-T X.509, of which X.509 v3 is the most commonly used.

This chapter covers the following types of certificates:

- **CA certificate**—Certificate of a CA. Multiple CAs in a PKI system form a CA tree, with the root CA at the top. The root CA generates a self-signed certificate, and each lower level CA holds a CA certificate issued by the CA immediately above it. The chain of these certificates forms a chain of trust.
- **Registration authority (RA) certificate**—Certificate issued by a CA to an RA. RAs act as proxies for CAs to process enrollment requests in a PKI system.
- **Local certificate**—Certificate of a local PKI entity, which contains the entity's public key. Local certificates include the following types:
  - **CA-signed certificate**—Digital certificate signed and issued by a CA to the local PKI entity.
  - **Self-signed certificate**—Digital certificate signed and issued by the local PKI entity (the device) itself. When the device cannot request a local certificate from the CA, it can sign and issue a local certificate for communication with the peer to provide services. Using this type of certificate is simple in configuration but has low security. You can use self-signed certificates in scenarios with low security requirements.
- **Peer certificate**—CA-signed digital certificate of a peer, which contains the peer's public key.

Fingerprint of root CA certificate

Each root CA certificate has a unique fingerprint, which is the hash value of the certificate content. The fingerprint of a root CA certificate can be used to authenticate the validity of the root CA.

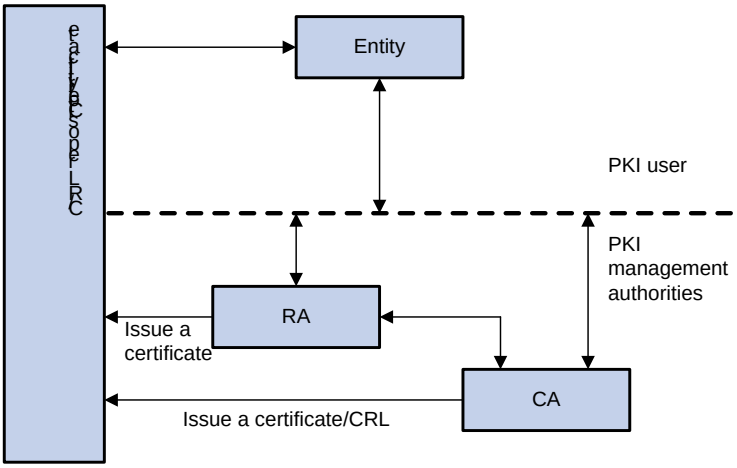
Certificate revocation list

A certificate revocation list (CRL) is a list of serial numbers for certificates that have been revoked. A CRL is created and signed by the CA that originally issued the certificates.

The CA publishes CRLs periodically to revoke certificates. Entities that are associated with the revoked certificates should not be trusted.

The CA must revoke a certificate when any of the following conditions occurs:

- The certificate subject name is changed.
- The private key is compromised.
- The association between the subject and CA is changed. For example, when an employee terminates employment with an organization.



CA policy

A CA policy is a set of criteria that a CA follows to process certificate requests, to issue and revoke certificates, and to publish CRLs. Typically, a CA advertises its policy in a certification practice statement (CPS). You can obtain a CA policy through out-of-band means such as phone, disk, and email. Make sure you understand the CA policy before you select a trusted CA for certificate request because different CAs might use different policies.

PKI architecture

A PKI system consists of PKI entities, CAs, RAs and a certificate/CRL repository, as shown in Figure 1.

Figure 1 PKI architecture

PKI entity

A PKI entity is an end user using PKI certificates. The PKI entity can be an operator, an organization, a device like a router or a switch, or a process running on a computer. PKI entities use SCEP to communicate with the CA or RA.

CA

Certification authority that grants and manages certificates. A CA issues certificates, defines the certificate validity periods, and revokes certificates by publishing CRLs.

RA

Registration authority, which offloads the CA by processing certificate enrollment requests. The RA accepts certificate requests, verifies user identity, and determines whether to ask the CA to issue certificates.

The RA is optional in a PKI system. In cases when there is security concern over exposing the CA to direct network access, it is advisable to delegate some of the tasks to an RA. Then, the CA can concentrate on its primary tasks of signing certificates and CRLs.

Certificate/CRL repository

A certificate distribution point that stores certificates and CRLs, and distributes these certificates and CRLs to PKI entities. It also provides the query function. A PKI repository can be a directory server using the LDAP or HTTP protocol, of which LDAP is commonly used.

Retrieval, usage, and maintenance of a digital certificate

The following workflow describes the retrieval, usage, and maintenance of a digital certificate. This example uses a CA which has an RA to process certificate enrollment requests.

1. A PKI entity generates an asymmetric key pair and submits a certificate request to the RA.

   The certificate request contains the public key and its identity information.
2. The RA verifies the identity of the entity and sends a digital signature containing the identity information and the public key to the CA.
3. The CA verifies the digital signature, approves the request, and issues a certificate.
4. After receiving the certificate from the CA, the RA sends the certificate to the certificate repository and notifies the PKI entity that the certificate has been issued.
5. The PKI entity obtains the certificate from the certificate repository.
6. To establish a secure connection for communication, two PKI entities exchange local certificates to authenticate each other. The connection can be established only if both entities verify that the peer's certificate is valid.
7. You can remove the local certificate of a PKI entity and request a new one when any of the following conditions occur:
   - The local certificate is about to expire.
   - The certificate's private key is compromised.

PKI applications

The PKI technology can meet security requirements of online transactions. As an infrastructure, PKI has a wide range of applications. H3C's PKI system can provide certificate management for IPsec and SSL.

The following are some application examples.

VPN

A VPN is a private data communication network built on the public communication infrastructure. A VPN can use network layer security protocols (for example, IPsec) in conjunction with PKI-based encryption and digital signature technologies for confidentiality.

Secure emails

PKI can address the email requirements for confidentiality, integrity, authentication, and non-repudiation. A common secure email protocol is Secure/Multipurpose Internet Mail Extensions (S/MIME), which is based on PKI and allows for transfer of encrypted mails with signature.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

PKI tasks at a glance

To configure PKI, perform the following tasks:

1. Configuring a PKI entity
2. Configuring a PKI domain
3. (Optional.) Specifying the storage path for certificates and CRLs
4. Requesting a certificate

   Choose one of the following tasks:

   - Enabling the automatic online certificate request mode
   - Manually submitting an online certificate request
   - Manually submitting a certificate request in offline mode
5. (Optional.) Aborting a certificate request
6. (Optional.) Obtaining certificates

   You can obtain the CA certificate, local certificates, and peer certificates related to a PKI domain from a CA and save them locally for higher lookup efficiency.
7. (Optional.) Verifying PKI certificates
8. (Optional.) Exporting certificates
9. (Optional.) Removing a certificate
10. (Optional.) Configuring a certificate-based access control policy

    Certificate-based access control policies allow you to authorize access to a device (for example, an HTTPS server) based on the attributes of an authenticated client's certificate.
11. (Optional.) Enabling local certificate expiration notification
12. (Optional.) Enabling SNMP notifications for PKI
13. (Optional.) Enabling PKI logging

Configuring a PKI entity

About this task

A certificate applicant uses an entity to provide its identity information to a CA. A valid PKI entity must include one or more of following identity categories:

- Distinguished name (DN) of the entity, which further includes the common name, country code, locality, organization, unit in the organization, and state. If you configure the DN for an entity, a common name is required.
- FQDN of the entity.
- IP address of the entity.

Restrictions and guidelines

Follow these restrictions and guidelines when you configure a PKI entity:

- Whether the identity categories are required or optional depends on the CA policy. Follow the CA policy to configure the entity settings. For example, if the CA policy requires the entity DN, but you configure only the IP address, the CA rejects the certificate request from the entity.
- The SCEP add-on on the Windows 2000 CA server has restrictions on the data length of a certificate request. If a request from a PKI entity exceeds the data length limit, the CA server does not respond to the certificate request. In this case, you can use an out-of-band means to submit the request. Other types of CA servers, such as RSA servers and OpenCA servers, do not have such restrictions.

Procedure

1. Enter system view.
   system-view
2. Create a PKI entity and enter its view.
   pki entity *entity-name*
3. Set a common name for the entity.
   common-name *common-name-sting*
   By default, the common name is not set.
4. Set the country code of the entity.
   country *country-code-string*
   By default, the country code is not set.
5. Set the locality of the entity.
   locality *locality-name*
   By default, the locality is not set.
6. Set the organization of the entity.
   organization *org-name*
   By default, the organization is not set.
7. Set the unit of the entity in the organization.
   organization-unit *org-unit-name*
   By default, the unit is not set.
8. Set the state where the entity resides.
   state *state-name*
   By default, the state is not set.
9. Set the FQDN of the entity.
   fqdn *fqdn-name-string*
   By default, the FQDN is not set.
10. Configure the IP address of the entity.
    ip { *ip-address* | **interface** *interface-type interface-number* }
    By default, the IP address is not configured.
11. Configure the title of the entity.
    title *title*
    By default, the title is not configured.

Configuring a PKI domain

About PKI domain

A PKI domain contains enrollment information for a PKI entity. It is locally significant and is intended only for use by other applications like IKE and SSL.

PKI domain tasks at a glance

To configure a PKI domain, perform the following tasks:

1. Creating a PKI domain

2. Specifying the trusted CA
3. Specifying the PKI entity name
4. Specifying the certificate request reception authority
5. Specifying the certificate request URL
6. (Optional.) Setting the SCEP polling interval and maximum polling attempts
7. Specifying the LDAP server

   This task is required when either of the following conditions is met:

   - The device must obtain certificates from the CA by using the LDAP protocol.
   - An LDAP URL which does not contain the host name of the LDAP server is specified as the CRL repository URL.
8. Specifying the fingerprint for root CA certificate verification

   This step is required if the auto certificate request mode is configured in the PKI domain.

   If the manual certificate request mode is configured, you can skip this step and manually verify the fingerprint displayed during verification of the root CA certificate.
9. Specifying the key pair for certificate request
10. (Optional.) Specifying the intended purpose for the certificate
11. (Optional.) Specifying the source IP address for PKI protocol packets

Creating a PKI domain

1. Enter system view.

   system-view
2. Create a PKI domain and enter its view.

   pki domain *domain-name*

Specifying the trusted CA

About this task

The PKI domain must have a CA certificate before you can request a local certificate. To obtain a CA certificate, the trusted CA name must be specified. The trusted CA name uniquely identifies the CA to be used if multiple CAs exist on the CA server.

Procedure

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. Specify the trusted CA name.

   ca identifier *name*

   By default, no trusted CA name is specified.

Specifying the PKI entity name

1. Enter system view.

   system-view
2. Enter PKI domain view.

pki domain *domain-name*

3. Specify the PKI entity name.
   certificate request entity *entity-name*
   By default, no PKI entity name is specified.

Specifying the certificate request reception authority

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Specify the certificate request reception authority.
   certificate request from { **ca** | **ra** }
   By default, no certificate request reception authority is specified.

Specifying the certificate request URL

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Specify the URL of the certificate request reception authority to which the device sends certificate requests.
   certificate request url *url-string* [**vpn-instance** *vpn-instance-name*]
   By default, the certificate request URL is not specified.

Setting the SCEP polling interval and maximum polling attempts

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Set the SCEP polling interval and maximum number of polling attempts.
   certificate request polling { **count** *count* | **interval** *interval* }
   By default, the device polls the CA server for the certificate request status every 20 minutes. The maximum number of polling attempts is 50.

Specifying the LDAP server

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Specify the LDAP server.

ldap-server host *hostname* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]

By default, no LDAP server is specified.

Specifying the fingerprint for root CA certificate verification

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. Configure the fingerprint for verifying the root CA certificate.

   In non-FIPS mode:

   root-certificate fingerprint { **md5** | **sha1** } *string*

   In FIPS mode:

   root-certificate fingerprint sha1 *string*

   By default, no fingerprint is configured.

Specifying the key pair for certificate request

Restrictions and guidelines

You can specify a nonexistent key pair for certificate request. The PKI entity automatically creates the key pair before submitting a certificate request.

Procedure

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. Specify the key pair for certificate request.
   - Specify an RSA key pair.

     public-key rsa { { **encryption name** *encryption-key-name* [**length** *key-length*] | **signature name** *signature-key-name* [**length** *key-length*] } * | **general name** *key-name* [**length** *key-length*] }
   - Specify an ECDSA key pair.

     In non-FIPS mode:

     public-key ecdsa name *key-name* [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**]

     In FIPS mode:

     public-key ecdsa name *key-name* [**secp256r1** | **secp384r1** | **secp521r1**]
   - Specify a DSA key pair.

     public-key dsa name *key-name* [**length** *key-length*]

     This command is supported only in non-FIPS mode.

   By default, no key pair is specified.

Specifying the intended purpose for the certificate

About this task

An issued certificate contains the extensions which restrict the usage of the certificate to specific purposes. You can specify the intended purposes for a certificate, which will be included in the certificate request sent to the CA. However, the actual extensions contained in an issued certificate depend on the CA policy, and they might be different from those specified in the PKI domain. Whether an application will use the certificate during authentication depends on the application's policy.

Supported certificate extensions include:

- **ike**—Certificates carrying this extension can be used by IKE peers.
- **ssl-client**—Certificates carrying this extension can be used by SSL clients.
- **ssl-server**—Certificates carrying this extension can be used by SSL servers.

Procedure

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. Specify the intended use for the certificate.

   usage { **ike** | **ssl-client** | **ssl-server** } *

   By default, the certificate can be used by all supported applications, including IKE, SSL client, and SSL server.

Specifying the source IP address for PKI protocol packets

About this task

This task is required if the CA policy requires that the CA server accept certificate requests from a specific IP address or subnet.

Procedure

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. Specify a source IP address for the PKI protocol packets.

   IPv4:

   source ip { *ip-address* | **interface** *interface-type interface-number* }

   IPv6:

   source ipv6 { *ipv6-address* | **interface** *interface-type interface-number* }

   By default, the source IP address of PKI protocol packets is the IP address of their outgoing interface.

Specifying the storage path for certificates and CRLs

About this task

The device has a default storage path for certificates and CRLs. You can change the storage path and specify different paths for the certificates and CRLs.

After you change the storage path for certificates or CRLs, the certificate files and CRL files in the original path are moved to the new path. Certificate files use the .cer or .p12 file extension and CRL files use the .crl file extension.

Restrictions and guidelines

If you change the storage path, save the configuration before you reboot or shut down the device to avoid loss of certificates or CRLs.

Procedure

1. Enter system view.

   system-view

2. Specify the storage path for certificates and CRLs.

   pki storage { **certificates** | **crls** } *dir-path*

   By default, the device stores certificates and CRLs in the PKI directory on the storage media of the device.

Requesting a certificate

About certificate request configuration

To request a certificate, a PKI entity must provide its identity information and public key to a CA.

A certificate request can be submitted to a CA in offline or online mode.

- **Offline mode**—A certificate request is submitted by using an out-of-band method, such as phone, disk, or email.
- **Online mode**—A certificate request can be automatically or manually submitted to a CA through the Simple Certificate Enrollment Protocol (SCEP).

Restrictions and guidelines for certificate request configuration

When you request a local certificate in a PKI domain, follow these restrictions and guidelines:

- To prevent an existing local certificate from becoming invalid, do not perform the following tasks:
  - Create a key pair with the same name as the key pair contained in the certificate.

    To create a key pair, use the **public-key local create** command.
  - Destroy the key pair contained in the certificate.

    To destroy a key pair, use the **public-key local destroy** command.
- To manually request a new certificate in a PKI domain that already has a local certificate, use the following procedure:

  a. Use the **pki delete-certificate** command to delete the existing local certificate.

b. Use the **public-key local create** command to generate a new key pair.

c. Manually submit a certificate request.

- A PKI domain can have local certificates using only one type of cryptographic algorithms (DSA, ECDSA, or RSA). If DSA or ECDSA is used, a PKI domain can have only one local certificate. If RSA is used, a PKI domain can have one local certificate for signature, and one local certificate for encryption.

Prerequisites for certificate request configuration

Make sure the device is time synchronized with the CA server. If the device is not time synchronized with the CA server, the certificate request might fail because the certificate might be considered to be outside of the validity period. For information about configuring the system time, see *Fundamentals Configuration Guide*.

Enabling the automatic online certificate request mode

About this task

In auto request mode, a PKI entity with no local certificates automatically submits a certificate request to the CA when an application works with the PKI entity. For example, when IKE negotiation uses a digital signature for identity authentication, but no local certificate is available, the entity automatically submits a certificate request. It saves the certificate locally after obtaining the certificate from the CA.

A CA certificate must be present before you request a local certificate. If no CA certificate exists in the PKI domain, the PKI entity automatically obtains a CA certificate before sending a certificate request.

Restrictions and guidelines

In auto request mode, the device does not automatically request a new certificate if the current certificate is about to expire or has expired, which might cause service interruptions.

Procedure

1. Enter system view.

system-view

2. Enter PKI domain view.

pki domain *domain-name*

3. Enable the automatic online certificate request mode.

certificate request mode auto [**password** { **cipher** | **simple** } *string*]

By default, the manual request mode applies.

If the CA policy requires a password for certificate revocation, specify the password in this command.

Manually submitting an online certificate request

About this task

In manual request mode, you must execute the **pki request-certificate domain** command to request a local certificate in a PKI domain. The certificate will be saved in the domain after it is obtained from the CA.

Procedure

1. Enter system view.

system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Set the certificate request mode to manual.

   certificate request mode manual

   By default, the manual request mode applies.

4. Return to system view.

   quit

5. Obtain a CA certificate.

   See "Obtaining certificates."

   This step is required if the PKI domain does not have a CA certificate. The CA certificate is used to verify the authenticity and validity of the obtained local certificate.

6. Manually submit an SCEP certificate request.

   pki request-certificate domain *domain-name* [**password** *password*]

   This command is not saved in the configuration file.

   If the CA policy requires a password for certificate revocation, specify the password in this command.

Manually submitting a certificate request in offline mode

About this task

Use this method if the CA does not support SCEP or if a network connection between the device and CA is not possible.

Procedure

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Set the certificate request mode to manual.

   certificate request mode manual

   By default, the manual request mode applies.

4. Return to system view.

   quit

5. Obtain the CA certificate.

   See "Obtaining certificates."

   This step is required if the PKI domain does not have a CA certificate. The CA certificate is used to verify the authenticity and validity of the obtained local certificate.

6. Print the certificate request in PKCS10 format on the terminal or save the certificate request to a PKCS10 file.

   pki request-certificate domain *domain-name* **pkcs10** [**filename** *filename*]

   This command is not saved in the configuration file.

7. Transfer certificate request information to the CA by using an out-of-band method.

8. Transfer the issued local certificate from the CA to the local device by using an out-of-band method.

9. Import the local certificate to the PKI domain.

   pki import domain *domain-name* { **der local filename** *filename* | **p12 local filename** *filename* | **pem local** [**filename** *filename*] }

Aborting a certificate request

About this task

Before the CA issues a certificate, you can abort a certificate request and change its parameters, such as the common name, country code, or FQDN. You can use the **display pki certificate request-status** command to display the status of a certificate request.

Alternatively, you also can remove a PKI domain to abort the associated certificate request.

Procedure

1. Enter system view.

   system-view

2. Abort a certificate request.

   pki abort-certificate-request domain *domain-name*

   This command is not saved in the configuration file.

Obtaining certificates

About this task

You can obtain the CA certificate, local certificates, and peer certificates related to a PKI domain from a CA and save them locally for higher lookup efficiency. To do so, use either the offline mode or the online mode:

- In offline mode, obtain the certificates by an out-of-band means like FTP, disk, or email, and then import them locally. Use this mode when the CRL repository is not specified, the CA server does not support SCEP, or the CA server generates the key pair for the certificates.
- In online mode, you can obtain the CA certificate through SCEP and obtain local certificates or peer certificates through LDAP.

Restrictions and guidelines

Follow these restrictions and guidelines when obtain certificates from a CA

- If a CA certificate already exists locally, you cannot obtain it again in online mode. If you want to obtain a new CA certificate, use the **pki delete-certificate** command to delete the existing CA certificate and local certificates first.
- If local or peer certificates already exist, you can obtain new local or peer certificates to overwrite the existing ones. If RSA is used, a PKI domain can have two local certificates, one for signature and the other for encryption.
- If CRL checking is enabled, obtaining a certificate triggers CRL checking. If the certificate to be obtained has been revoked, the certificate cannot be obtained.
- The device compares the validity period of a certificate with the local system time to determine whether the certificate is valid. Make sure the system time of the device is synchronized with the CA server.

Prerequisites

- Before you obtain local or peer certificates in online mode, make sure an LDAP server is correctly configured in the PKI domain.
- Before you import certificates in offline mode, complete the following tasks:

- Use FTP or TFTP to upload the certificate files to the storage media of the device.

  If FTP or TFTP is not available, display and copy the contents of a certificate to a file on the device. Make sure the certificate is in PEM format because only certificates in PEM format can be imported.
- Before you import a local certificate or peer certificate, obtain the CA certificate chain that signs the certificate.

  This step is required only if the CA certificate chain is neither available in the PKI domain nor contained in the certificate to be imported.
- Before you import a local certificate that contains an encrypted key pair, contact the CA administrator to obtain the password required for importing the certificate.

Procedure

1. Enter system view.

   system-view
2. Obtain certificates.
   - Import certificates in offline mode.

     pki import domain *domain-name* { **der** { **ca** | **local** | **peer** } **filename** *filename* | **p12 local filename** *filename* | **pem** { **ca** | **local** | **peer** } [**filename** *filename*] }
   - Obtain certificates in online mode.

     pki retrieve-certificate domain *domain-name* { **ca** | **local** | **peer** *entity-name* }

     This command is not saved in the configuration file.

Verifying PKI certificates

About certification verification

A certificate is automatically verified when it is requested, obtained, or used by an application. If the certificate expires, if it is not issued by a trusted CA, or if it is revoked, the certificate cannot be used You can also manually verify a certificate.

You can enable or disable CRL checking in a PKI domain. CRL checking checks whether a certificate is in the CRL. If it is, the certificate has been revoked and its home entity is not trusted.

To use CRL checking, a CRL must be obtained from a CRL repository. The device selects a CRL repository in the following order:

1. CRL repository specified in the PKI domain by using the **crl url** command.
2. CRL repository in the certificate that is being verified.
3. CRL repository in the CA certificate or CRL repository in the upper-level CA certificate if the certificate being verified is a CA certificate

If no CRL repository is found after the selection process, the device obtains the CRL through SCEP. In this scenario, the CA certificate and the local certificates must have been obtained.

A certificate fails CRL checking in the following situations:

- A CRL cannot be obtained during CRL checking of the certificate.
- CRL checking verifies that the certificate has been revoked.

Restrictions and guidelines for certificate verification

When verifying the CA certificate of a PKI domain, the system needs to verify all the certificates in the CA certificate chain. To ensure a successful certificate verification process, the device must have all the PKI domains to which the CA certificates in the certificate chain belong.

The system verifies the CA certificates in the CA certificate chain as follows:

1. Identifies the parent certificate of the lowest-level certificate.

   Each CA certificate contains an issuer field that identifies the parent CA that issued the certificate.
2. Locates the PKI domain to which the parent certificate belongs.
3. Performs CRL checking in the PKI domain to check whether the parent certificate has been revoked. If it has been revoked, the certificate cannot be used.

   This step will not be performed when CRL checking is disabled in the PKI domain.
4. Repeats the previous steps for upper-level certificates in the CA certificate chain until the root CA certificate is reached.
5. Verifies that each CA certificate in the certificate chain is issued by the named parent CA, starting from the root CA.

Verifying certificates with CRL checking

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. (Optional.) Specify the URL of the CRL repository.

   crl url *url-string* [**vpn-instance** *vpn-instance-name*]

   By default, the URL of the CRL repository is not specified.
4. Enable CRL checking.

   crl check enable

   By default, CRL checking is enabled.
5. Return to system view.

   quit
6. Obtain the CA certificate.

   See "Obtaining certificates."

   The PKI domain must have a CA certificate before you can verify certificates in it.
7. (Optional.) Obtain the CRL.
   - Obtain the CRL from the CRL repository and save it locally.

     pki retrieve-crl domain *domain-name*

     To verify a non-root CA certificate and local certificates, the device automatically retrieves the CRL if the PKI domain has no CRL.

     The newly obtained CRL overwrites the old one, if any.

     The obtained CRL is issued by a CA in the CA certificate chain stored in the PKI domain.
   - Import a CRL file in the specified local path.

     pki retrieve-crl domain *domain-name*

     Use this method if no CRL repository exists in the environment.
8. Manually verify the validity of the certificates.

pki validate-certificate domain *domain-name* { **ca** | **local** }

Verifying certificates without CRL checking

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Disable CRL checking.
   undo crl check enable
   By default, CRL checking is enabled.
4. Return to system view.
   quit
5. Obtain a CA certificate for the PKI domain.
   See "Obtaining certificates."
   The PKI domain must have a CA certificate before you can verify certificates in it.
6. Manually verify the certificate validity.
   pki validate-certificate domain *domain-name* { **ca** | **local** }
   This command is not saved in the configuration file.

Exporting certificates

About this task

You can export the CA certificate and the local certificates in a PKI domain to certificate files. The exported certificate files can then be imported back to the device or other PKI applications.

Restrictions and guidelines

To export all certificates in PKCS12 format, the PKI domain must have a minimum of one local certificate. If the PKI domain does not have any local certificates, the certificates in the PKI domain cannot be exported.

If you do not specify a file name when you export a certificate in PEM format, this command displays the certificate content on the terminal.

When you export a local certificate with RSA key pairs to a file, the certificate file name might be different from the file name specified in the command. The actual certificate file name depends on the purpose of the key pair contained in the certificate. For more information about the file naming rule, see the **pki export** command in *Security Command Reference*.

Procedure

1. Enter system view.
   system-view
2. Export certificates.
   - Export certificates in DER format.
     pki export domain *domain-name* **der** { **all** | **ca** | **local** } **filename** *filename*
   - Export certificates in PKCS12 format.
     pki export domain *domain-name* **p12** { **all** | **local** } **passphrase** *p12-key* **filename** *filename*

- Export certificates in PEM format.

  pki export domain *domain-name* **pem** { { **all** | **local** } [{ **3des-cbc** | **aes-128-cbc** | **aes-192-cbc** | **aes-256-cbc** | **des-cbc** } *pem-key*] | **ca** } [**filename** *filename*]

Removing a certificate

About this task

You can remove certificates from a PKI domain in the following situations:

- Remove a CA certificate, local certificate, or peer certificate if the certificate has expired or is about to expire.
- Remove a local certificate if the certificate's private key is compromised, or if you want to request a new local certificate to replace the existing one.

Restrictions and guidelines

After you remove the CA certificate, the system automatically removes the local certificates, peer certificates, and CRLs from the domain.

To remove a local certificate and request a new certificate, perform the following tasks:

1. Remove the local certificate.
2. Use the **public-key local destroy** command to destroy the existing local key pair.
3. Use the **public-key local create** command to generate a new key pair.
4. Request a new certificate.

For more information about the **public-key local destroy** and **public-key local create** commands, see *Security Command Reference*.

Procedure

1. Enter system view.

   system-view
2. Remove a certificate.

   pki delete-certificate domain *domain-name* { **ca** | **local** | **peer** [**serial** *serial-num*] }

   If you use the **peer** keyword without specifying a serial number, this command removes all peer certificates.

Configuring a certificate-based access control policy

About certificate-based access control policies

Certificate-based access control policies allow you to authorize access to a device (for example, an HTTPS server) based on the attributes of an authenticated client's certificate.

Access control rules and certificate attribute groups

A certificate-based access control policy is a set of access control rules (permit or deny statements), each associated with a certificate attribute group. A certificate attribute group contains multiple attribute rules, each defining a matching criterion for an attribute in the certificate issuer name, subject name, or alternative subject name field.

Certificate matching mechanism

If a certificate matches all attribute rules in a certificate attribute group associated with an access control rule, the system determines that the certificate matches the access control rule. In this scenario, the match process stops, and the system performs the access control action defined in the access control rule.

The following conditions describe how a certificate-based access control policy verifies the validity of a certificate:

- If a certificate matches a permit statement, the certificate passes the verification.
- If a certificate matches a deny statement or does not match any statements in the policy, the certificate is regarded invalid.
- If a statement is associated with a non-existing attribute group, or the attribute group does not have attribute rules, the certificate matches the statement.
- If the certificate-based access control policy specified for a security application (for example, HTTPS) does not exist, all certificates in the application pass the verification.

Procedure

1. Enter system view.

   system-view
2. Create a certificate attribute group and enter its view.

   pki certificate attribute-group *group-name*
3. Configure an attribute rule for issuer name, subject name, or alternative subject name.

   attribute *id* { **alt-subject-name** { **fqdn** | **ip** } | { **issuer-name** | **subject-name** } { **dn** | **fqdn** | **ip** } } { **ctn** | **equ** | **nctn** | **nequ**} *attribute-value*

   By default, not attribute rules are configured.
4. Return to system view.

   quit
5. Create a certificate-based access control policy and enter its view.

   pki certificate access-control-policy *policy-name*

   By default, no certificate-based access control policies exist.
6. Create a certificate access control rule.

   rule [*id*] { **deny** | **permit** } *group-name*

   By default, no certificate access control rules are configured, and all certificates can pass the verification.

   You can create multiple certificate access control rules for a certificate-based access control policy.

Enabling local certificate expiration notification

About this task

After this feature is enabled, the system checks the validity date for local certificates every other hour. When a local certificate is about to expire in 30 days (included) or has expired, the system sends a notification log message for the certificate every other day.

Procedure

1. Enter system view.

system-view

2. Enable local certificate expiration notification.

   pki certificate logging { **local-will-expire** | **local-has-expired** } **enable**

   By default, local certificate expiration notification is disabled.

Enabling SNMP notifications for PKI

About this task

To report critical PKI events to an NMS, enable SNMP notifications for PKI. For PKI notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP notifications, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

For the device to generate and output certain types of PKI notifications, enable global PKI notifications and those types of PKI notifications. For the device to stop generating certain types of PKI notifications, disable those types of PKI notifications.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for PKI.

   snmp-agent trap enable pki [**ca-cert-invalid** | **ca-cert-valid** | **crl-http-failure** | **crl-http-success** | **crl-invalid** | **crl-ldap-failure** | **crl-ldap-success** | **crl-scep-failure** | **crl-scep-success** | **crl-valid** | **get-ca-failure** | **get-crl-failure** | **global** | **local-cert-has-expired** | **local-cert-invalid** | **local-cert-ldap-failure**| **local-cert-ldap-success** | **local-cert-nearly-expired** | **local-cert-scep-failure** | **local-cert-scep-success** | **local-cert-valid**] *

   By default, SNMP notifications for PKI are disabled.

Enabling PKI logging

About this task

PKI log messages help administrators easily locate and resolve issues. PKI logging allows the device to record the events and errors on the PKI module and output the corresponding log messages.

These PKI log messages will be sent to the information center. The configuration for the information center determines the output rules and destinations for the PKI log messages. For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

Recording PKI logs consumes memory resources. As a best practice to prevent excessive logging, do not enable this feature unless auditing or troubleshooting is needed.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for PKI.
   pki logging enable
   By default, PKI logging is disabled.

Display and maintenance commands for PKI

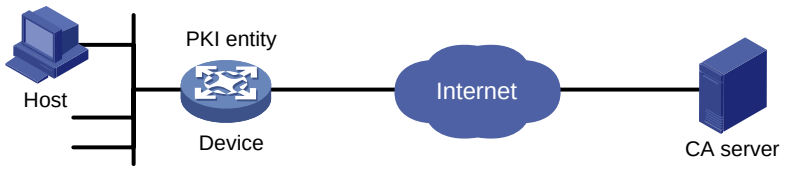
Execute **display** commands in any view.

Task	Command
Display certificate-based access control policy information.	**display pki certificate access-control-policy** [*policy-name*]
Display certificate attribute group information.	**display pki certificate attribute-group** [*group-name*]
Display the contents of a certificate.	**display pki certificate domain** *domain-name* { **ca** | **local** | **peer** [**serial** *serial-num*] }
Display certificate request status.	**display pki certificate request-status** [**domain** *domain-name*]
Display locally stored CRLs in a PKI domain.	**display pki crl domain** *domain-name*

PKI configuration examples

You can use different software applications, such as Windows server, RSA Keon, and OpenCA, to act as the CA server.

If you use Windows server or OpenCA, you must install the SCEP add-on for Windows server or enable SCEP for OpenCA. In either case, when you configure a PKI domain, you must use the **certificate request from ra** command to specify the RA to accept certificate requests.



If you use RSA Keon, the SCEP add-on is not required. When you configure a PKI domain, you must use the **certificate request from ca** command to specify the CA to accept certificate requests.

Example: Requesting a certificate from an RSA Keon CA server

Network configuration

Configure the PKI entity (the device) to request a local certificate from the CA server.

Figure 2 Network diagram

Configuring the RSA Keon CA server

1. Create a CA server named **myca**:

In this example, you must configure these basic attributes on the CA server:

- **Nickname**—Name of the trusted CA.
- **Subject DN**—DN attributes of the CA, including the common name (CN), organization unit (OU), organization (O), and country (C).

You can use the default values for other attributes.

2. Configure extended attributes:

   Configure parameters in the **Jurisdiction Configuration** section on the management page of the CA server:

   - Select the correct extension profiles.
   - Enable the SCEP autovetting function to enable the CA server to automatically approve certificate requests without manual intervention.
   - Specify the IP address list for SCEP autovetting.

Configuring the device

1. Synchronize the system time of the device with the CA server for the device to correctly request certificates or obtain CRLs. (Details not shown.)
2. Create an entity named **aaa** and set the common name to **Device**.

```
<Device> system-view
[Device] pki entity aaa
[Device-pki-entity-aaa] common-name Device
[Device-pki-entity-aaa] quit
```

3. Configure a PKI domain:

   # Create a PKI domain named **torsa** and enter its view.

```
[Device] pki domain torsa
```

   # Specify the name of the trusted CA. The setting must be the same as CA name configured on the CA server. This example uses **myca**.

```
[Device-pki-domain-torsa] ca identifier myca
```

   # Configure the URL of the CA server. The URL format is **http://***host:port***/***Issuing Jurisdiction ID*, where *Issuing Jurisdiction ID* is a hexadecimal string generated on the CA server.

```
[Device-pki-domain-torsa] certificate request url
http://1.1.2.22:446/80f6214aa8865301d07929ae481c7ceed99f95bd
```

   # Configure the device to send certificate requests to **ca**.

```
[Device-pki-domain-torsa] certificate request from ca
```

   # Set the PKI entity name to **aaa**.

```
[Device-pki-domain-torsa] certificate request entity aaa
```

   # Specify the URL of the CRL repository.

```
[Device-pki-domain-torsa] crl url ldap://1.1.2.22:389/CN=myca
```

   # Specify a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[Device-pki-domain-torsa] public-key rsa general name abc length 1024
[Device-pki-domain-torsa] quit
```

4. Generate the RSA key pair.

```
[Device] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
```

```
.........................++++++
.....................................++++++
Create the key pair successfully.
```

5. Request a local certificate:

Obtain the CA certificate and save it locally.

```
[Device] pki retrieve-certificate domain torsa ca
The trusted CA's finger print is:
    MD5  fingerprint:EDE9 0394 A273 B61A F1B3 0072 A0B1 F9AB
    SHA1 fingerprint: 77F9 A077 2FB8 088C 550B A33C 2410 D354 23B2 73A8
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

Submit a certificate request manually and set the certificate revocation password to **1111**. The certificate revocation password is required when an RSA Keon CA server is used.

```
[Device] pki request-certificate domain torsa password 1111
Start to request general certificate ...
……
Request certificate of domain torsa successfully
```

Verifying the configuration

Display information about the local certificate in PKI domain **torsa**.

```
[Device] display pki certificate domain torsa local
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number:

```

To display detailed information about the CA certificate, use the **display pki certificate domain** command.

Example: Requesting a certificate from a Windows Server 2003 CA server

Network configuration

Configure the PKI entity (the device) to request a local certificate from a Windows Server 2003 CA server.

Figure 3 Network diagram

Configuring the Windows Server 2003 CA server

1. Install the certificate service component:
   a. Select **Control Panel** > **Add or Remove Programs** from the start menu.
   b. Select **Add/Remove Windows Components** > **Certificate Services**.
   c. Click **Next** to begin the installation.
   d. Set the CA name. In this example, set the CA name to **myca**.
2. Install the SCEP add-on:

   By default, Windows Server 2003 does not support SCEP. You must install the SCEP add-on on the server for a PKI entity to register and obtain a certificate from the server. After the SCEP add-on installation is complete, you will see a URL. Specify this URL as the certificate request URL on the device.
3. Modify the certificate service attributes:
   a. Select **Control Panel** > **Administrative Tools** > **Certificate Authority** from the start menu.

      If the certificate service component and SCEP add-on have been installed successfully, there should be two certificates issued by the CA to the RA.
   b. Right-click the CA server in the navigation tree and select **Properties** > **Policy Module**.
   c. Click **Properties**, and then select **Follow the settings in the certificate template, if applicable. Otherwise, automatically issue the certificate**.
4. Modify the Internet information services attributes:

a. Select **Control Panel** > **Administrative Tools** > **Internet Information Services (IIS) Manager** from the start menu.
b. Select **Web Sites** from the navigation tree.
c. Right-click **Default Web Site** and select **Properties** > **Home Directory**.
d. Specify the path for certificate service in the **Local path** field.
e. Specify a unique TCP port number for the default website to avoid conflict with existing services. This example uses port 8080.

Configuring the device

1. Synchronize the device's system time with the CA server for the device to correctly request certificates. (Details not shown.)
2. Create an entity named **aaa** and set the common name to **test**.

```
<Device> system-view
[Device] pki entity aaa
[Device-pki-entity-aaa] common-name test
[Device-pki-entity-aaa] quit
```

3. Configure a PKI domain:

Create a PKI domain named **winserver** and enter its view.

```
[Device] pki domain winserver
```

Set the name of the trusted CA to **myca**.

```
[Device-pki-domain-winserver] ca identifier myca
```

Configure the certificate request URL. The URL format is **http://***host:port***/certsrv/mscep/mscep.dll**, where *host:port* is the host IP address and port number of the CA server.

```
[Device-pki-domain-winserver] certificate request url
http://4.4.4.1:8080/certsrv/mscep/mscep.dll
```

Configure the device to send certificate requests to **ra**.

```
[Device-pki-domain-winserver] certificate request from ra
```

Set the PKI entity name to **aaa**.

```
[Device-pki-domain-winserver] certificate request entity aaa
```

Configure a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[Device-pki-domain-winserver] public-key rsa general name abc length 1024
[Device-pki-domain-winserver] quit
```

4. Generate RSA key pair **abc**.

```
[Device] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

5. Request a local certificate:

Obtain the CA certificate and save it locally.

```
[Device] pki retrieve-certificate domain winserver ca
The trusted CA's finger print is:
    MD5  fingerprint:766C D2C8 9E46 845B 4DCE 439C 1C1F 83AB
```

```
    SHA1 fingerprint:97E5 DDED AB39 3141 75FB DB5C E7F8 D7D7 7C9B 97B4
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

Submit a certificate request manually.

```
[Device] pki request-certificate domain winserver
Start to request general certificate ...
…
Request certificate of domain winserver successfully
```

Verifying the configuration

Display information about the local certificate in PKI domain **winserver**.

```
[Device] display pki certificate domain winserver local
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number:
             (Negative)01:03:99:ff:ff:ff:ff:fd:11
        Signature Algorithm: sha1WithRSAEncryption
        Issuer: CN=sec
        Validity

```

To display detailed information about the CA certificate, use the **display pki certificate domain** command.

Example: Requesting a certificate from an OpenCA server

Network configuration

Configure the PKI entity (the device) to request a local certificate from the CA server.

Figure 4 Network diagram

Configuring the OpenCA server

Configure the OpenCA server as instructed in related manuals. (Details not shown.)

Make sure the version of the OpenCA server is later than version 0.9.2 because the earlier versions do not support SCEP.

Configuring the device

1. Synchronize the device's system time with the CA server for the device to correctly request certificates. (Details not shown.)
2. Create a PKI entity named **aaa** and configure the common name, country code, organization name, and OU for the entity.

```
<Device> system-view
[Device] pki entity aaa
[Device-pki-entity-aaa] common-name rnd
[Device-pki-entity-aaa] country CN
[Device-pki-entity-aaa] organization test
[Device-pki-entity-aaa] organization-unit software
[Device-pki-entity-aaa] quit
```

3. Configure a PKI domain:

   # Create a PKI domain named **openca** and enter its view.

```
[Device] pki domain openca
```

   # Set the name of the trusted CA to **myca**.

```
[Device-pki-domain-openca] ca identifier myca
```

   # Configure the certificate request URL. The URL is in the format **http://***host***/cgi-bin/pki/scep**, where *host* is the host IP address of the OpenCA server.

```
[Device-pki-domain-openca] certificate request url
http://192.168.222.218/cgi-bin/pki/scep
```

   # Configure the device to send certificate requests to the RA.

```
[Device-pki-domain-openca] certificate request from ra
```

   # Specify PKI entity **aaa** for certificate request.

```
[Device-pki-domain-openca] certificate request entity aaa
```

   # Configure a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[Device-pki-domain-openca] public-key rsa general name abc length 1024
[Device-pki-domain-openca] quit
```

4. Generate RSA key pair **abc**.

```
[Device] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

5. Request a local certificate:

   # Obtain the CA certificate and save it locally.

```
[Device] pki retrieve-certificate domain openca ca
The trusted CA's finger print is:
    MD5  fingerprint:5AA3 DEFD 7B23 2A25 16A3 14F4 C81C C0FA
```

```
    SHA1 fingerprint:9668 4E63 D742 4B09 90E0 4C78 E213 F15F DC8E 9122
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

Submit a certificate request manually.

```
[Device] pki request-certificate domain openca
Start to request general certificate ...
…
Request certificate of domain openca successfully
```

Verifying the configuration

Display information about the local certificate in PKI domain **openca**.

```
[Device] display pki certificate domain openca local

```

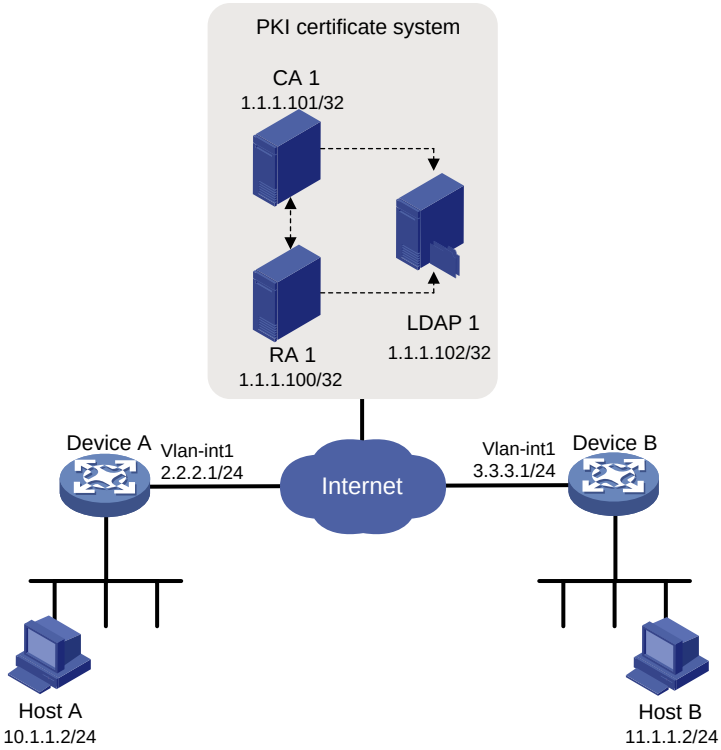
To display detailed information about the CA certificate, use the **display pki certificate domain** command.

Example: Configuring IKE negotiation with RSA digital signature from a Windows Server 2003 CA server



Network configuration

As shown in the network diagram, an IPsec tunnel is required to be established between Device A and Device B. The IPsec tunnel protects the traffic between Host A on subnet 10.1.1.0/24 and Host B on subnet 1.1.1.0/24.

Device A and Device B use IKE to set up SAs, and the IKE proposal uses RSA digital signature for identity authentication.

Device A and Device B use the same CA.

Figure 5 Network diagram

Configuring the Windows Server 2003 CA server

See "Example: Requesting a certificate from a Windows Server 2003 CA server."

Configuring Device A

Configure a PKI entity.

```
<DeviceA> system-view
[DeviceA] pki entity en
[DeviceA-pki-entity-en] ip 2.2.2.1
[DeviceA-pki-entity-en] common-name devicea
[DeviceA-pki-entity-en] quit
```

Configure a PKI domain.

```
[DeviceA] pki domain 1
[DeviceA-pki-domain-1] ca identifier CA1
[DeviceA-pki-domain-1] certificate request url http://1.1.1.100/certsrv/mscep/mscep.dll
[DeviceA-pki-domain-1] certificate request entity en
[DeviceA-pki-domain-1] ldap-server host 1.1.1.102
```

Configure the device to send certificate requests to **ra**.

```
[DeviceA-pki-domain-1] certificate request from ra
```

Configure a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[DeviceA-pki-domain-1] public-key rsa general name abc length 1024
[DeviceA-pki-domain-1] quit
```

Generate the RSA key pair.

```
[DeviceA] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
```

```
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

Obtain the CA certificate and save it locally.

```
[DeviceA] pki retrieve-certificate domain 1 ca
```

Submit a certificate request manually.

```
[DeviceA] pki request-certificate domain 1
```

Create IKE proposal 1, and configure the authentication method as RSA digital signature.

```
[DeviceA] ike proposal 1
[DeviceA-ike-proposal-1] authentication-method rsa-signature
[DeviceA-ike-proposal-1] quit
```

Specify the PKI domain used in IKE negotiation for IKE profile **peer**.

```
[DeviceA] ike profile peer
[DeviceA-ike-profile-peer] certificate domain 1
```

Configuring Device B

Configure a PKI entity.

```
<DeviceB> system-view
[DeviceB] pki entity en
[DeviceB-pki-entity-en] ip 3.3.3.1
[DeviceB-pki-entity-en] common-name deviceb
[DeviceB-pki-entity-en] quit
```

Configure a PKI domain.

```
[DeviceB] pki domain 1
[DeviceB-pki-domain-1] ca identifier CA1
[DeviceB-pki-domain-1] certificate request url http://1.1.1.100/certsrv/mscep/mscep.dll
[DeviceB-pki-domain-1] certificate request entity en
[DeviceB-pki-domain-1] ldap-server host 1.1.1.102
```

Configure the device to send certificate requests to **ra**.

```
[DeviceB-pki-domain-1] certificate request from ra
```

Configure a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[DeviceB-pki-domain-1] public-key rsa general name abc length 1024
[DeviceB-pki-domain-1] quit
```

Generate the RSA key pair.

```
[DeviceB] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

Obtain the CA certificate and save it locally.

```
[DeviceB] pki retrieve-certificate domain 1 ca
The trusted CA's finger print is:
    MD5  fingerprint:5C41 E657 A0D6 ECB4 6BD6 1823 7473 AABC
    SHA1 fingerprint:1616 E7A5 D89A 2A99 9419 1C12 D696 8228 87BC C266
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

Submit a certificate request manually.

```
[DeviceB] pki request-certificate domain 1
Start to request general certificate ...
...
Certificate requested successfully.
```

Create IKE proposal 1, and configure the authentication method as RSA digital signature.

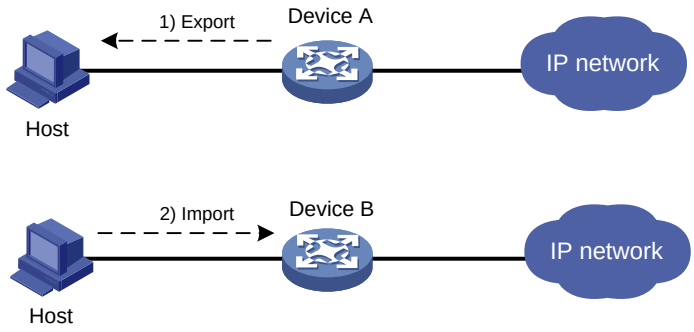
```
[DeviceB] ike proposal 1
[DeviceB-ike-proposal-1] authentication-method rsa-signature
[DeviceB-ike-proposal-1] quit
```

Specify the PKI domain used in IKE negotiation for IKE profile **peer**.

```
[DeviceB] ike profile peer
[DeviceB-ike-profile-peer] certificate domain 1
```

The configurations are for IKE negotiation with RSA digital signature. For information about how to configure IPsec SAs to be set up, see "Configuring IPsec."

Example: Importing and exporting certificates



Network configuration

As shown in Figure 6, Device B will replace Device A in the network. PKI domain **exportdomain** on Device A has two local certificates containing the private key and one CA certificate. To make sure the certificates are still valid after Device B replaces Device A, copy the certificates on Device A to Device B as follows:

1. Export the certificates in PKI domain **exportdomain** on Device A to .pem certificate files.

   During the export, encrypt the private key in the local certificates using 3DES_CBC with the password 11111.
2. Transfer the certificate files from Device A to Device B through the FTP host.
3. Import the certificate files to PKI domain **importdomain** on Device B.

Figure 6 Network diagram

Procedure

1. Export the certificates on Device A:

Export the CA certificate to a .pem file.

```
<DeviceA> system-view
[DeviceA] pki export domain exportdomain pem ca filename pkicachain.pem
```

Export the local certificate to a file named **pkilocal.pem** in PEM format, and use 3DES_CBC to encrypt the private key with the password **111111**.

```
[DeviceA] pki export domain exportdomain pem local 3des-cbc 111111 filename
pkilocal.pem
```

Now, Device A has three certificate files in PEM format:

- A CA certificate file named **pkicachain.pem**.
- A local certificate file named **pkilocal.pem-signature**, which contains the private key for signature.
- A local certificate file named **pkilocal.pem-encryption**, which contains the private key for encryption.

Display local certificate file **pkilocal.pem-signature**.

```
[DeviceA] quit
<DeviceA> more pkilocal.pem-signature

2. Download certificate files **pkicachain.pem**, **pkilocal.pem-signature**, and **pkilocal.pem-encryption** from Device A to the host through FTP. (Details not shown.)
3. Upload certificate files **pkicachain.pem**, **pkilocal.pem-signature**, and **pkilocal.pem-encryption** from the host to Device B through FTP. (Details not shown.)
4. Import the certificate files to Device B:

   # Disable CRL checking. (You can configure CRL checking as required. This example assumes CRL checking is not required.)

```
<DeviceB> system-view
[DeviceB] pki domain importdomain
[DeviceB-pki-domain-importdomain] undo crl check enable
```

   # Specify RSA key pair **sign** for signature and RSA key pair **encr** for encryption.

```
[DeviceB-pki-domain-importdomain] public-key rsa signature name sign encryption name encr
[DeviceB-pki-domain-importdomain] quit
```

   # Import CA certificate file **pkicachain.pem** in PEM format to the PKI domain.

```
[DeviceB] pki import domain importdomain pem ca filename pkicachain.pem
```

   # Import local certificate file **pkilocal.pem-signature** in PEM format to the PKI domain. The certificate file contains a key pair.

```
[DeviceB] pki import domain importdomain pem local filename pkilocal.pem-signature
Please input the password:
```

   # Import local certificate file **pkilocal.pem-encryption** in PEM format to the PKI domain. The certificate file contains a key pair.

```
[DeviceB] pki import domain importdomain pem local filename pkilocal.pem-encryption
Please input the password:
```

   # Display the imported local certificate information on Device B.

```
[DeviceB] display pki certificate domain importdomain local

To display detailed information about the CA certificate, use the **`display pki certificate domain`** command.

Troubleshooting PKI configuration

This section provides troubleshooting information for common problems with PKI.

Failed to obtain the CA certificate

Symptom

The CA certificate cannot be obtained.

Analysis

- The network connection is down, for example, because the network cable is damaged or the connectors have bad contact.
- No trusted CA is specified.
- The certificate request URL is incorrect or not specified.
- The system time of the device is not synchronized with the CA server.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.
- The fingerprint of the root CA certificate is illegal.

Solution

1. Fix the network connection problems, if any.
2. Configure the trusted CA and all other required parameters in the PKI domain.
3. Use the **ping** command to verify that the CA server is reachable.
4. Synchronize the system time of the device with the CA server.
5. Specify the correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
6. Verify the fingerprint of the CA certificate on the CA server.
7. If the problem persists, contact H3C Support.

Failed to obtain local certificates

Symptom

The local certificates can be obtained.

Analysis

- The network connection is down.
- The PKI domain does not have a CA certificate before you submit the local certificate request.
- The LDAP server is not configured or is incorrectly configured.
- No key pair is specified for certificate request in the PKI domain, or the specified key pair does not match the one contained in the local certificates to the obtained.
- No PKI entity is configured in the PKI domain, or the PKI entity configuration is incorrect.
- CRL checking is enabled, but the PKI domain does not have a CRL and cannot obtain one.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.
- The system time of the device is not synchronized with the CA server.

Solution

1. Fix the network connection problems, if any..
2. Obtain or import the CA certificate.
3. Configure the correct LDAP server parameters.
4. Specify the key pair for certificate request, or remove the existing key pair, specify a new key pair, and submit a local certificate request again.
5. Check the registration policy on the CA or RA, and make sure the attributes of the PKI entity meet the policy requirements.
6. Obtain the CRL from the CRL repository.
7. Specify the correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
8. Synchronize the system time of the device with the CA server.
9. If the problem persists, contact H3C Support.

Failed to request local certificates

Symptom

Local certificate requests cannot be submitted.

Analysis

- The network connection is down, for example, because the network cable is damaged or the connectors have bad contact.
- The PKI domain does not have a CA certificate before the local certificate request is submitted.
- The certificate request URL is incorrect or is not specified.
- The certificate request reception authority is incorrect or is not specified.
- Required PKI entity parameters are not configured or are incorrectly configured.
- No key pair is specified in the PKI domain for certificate request, or the key pair is changed during a certificate request process.
- Exclusive certificate request applications are running in the PKI domain.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.
- The system time of the device is not synchronized with the CA server.

Solution

1. Fix the network connection problems, if any.
2. Obtain or import the CA certificate.
3. Use the **ping** command to verify that the registration server is reachable.
4. Use the **certificate request from** command to specify the correct certificate request reception authority.
5. Configure the PKI entity parameters as required by the registration policy on the CA or RA.
6. Specify the key pair for certificate request, or remove the existing key pair, specify a new key pair, and submit a local certificate request again.
7. Use the **pki abort-certificate-request domain** command to abort the certificate request.
8. Specify the correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
9. Synchronize the system time of the device with the CA server.
10. If the problem persists, contact H3C Support.

Failed to obtain CRLs

Symptom

CRLs cannot be obtained.

Analysis

- The network connection is down, for example, because the network cable is damaged or the connectors have bad contact.
- The PKI domain does not have a CA certificate before you try to obtain CRLs.
- The URL of the CRL repository is not configured and cannot be obtained from the CA certificate or local certificates in the PKI domain.
- The specified URL of the CRL repository is incorrect.
- The device tries to obtain CRLs through SCEP, but it experiences the following problems:
  - The PKI domain does not have local certificates.
  - The key pairs in the certificates have been changed.
  - The PKI domain has incorrect URL for certificate request.

- The CRL repository uses LDAP for CRL distribution. However, the IP address or host name of the LDAP server is neither contained in the CRL repository URL nor configured in the PKI domain.
- The CA does not issue CRLs.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.

Solution

1. Fix the network connection problems, if any.
2. Obtain or import the CA certificate.
3. If the URL of the CRL repository cannot be obtained, verify that the following conditions exist:
   - The URL for certificate request is valid.
   - A local certificate has been successfully obtained.
   - The local certificate contains a public key that matches the locally stored key pair.
4. Make sure the LDAP server address is contained in the CRL repository URL, or is configured in the PKI domain.
5. Make sure the CA server support publishing CRLs.
6. Specify a correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
7. If the problem persists, contact H3C Support.

Failed to import the CA certificate

Symptom

The CA certificate cannot be imported.

Analysis

- CRL checking is enabled, but the device does not have a CRL in the PKI domain and cannot obtain one.
- The specified format in which the CA certificate file is to be imported does not match actual certificate file format.

Solution

1. Use the **`undo crl check enable`** command to disable CRL checking in the PKI domain.
2. Make sure the format of the imported file is correct.
3. If the problem persists, contact H3C Support.

Failed to import the local certificate

Symptom

The local certificate cannot be imported.

Analysis

- The PKI domain does not have a CA certificate, and the local certificate file to be imported does not contain the CA certificate chain.
- CRL checking is enabled, but the device does not have a CRL in the PKI domain and cannot obtain one.
- The specified format in which the local certificate file is to be imported does not match actual certificate file format.

- The device and the certificate do not have the local key pair.
- The certificate has been revoked.
- The certificate is out of the validity period.
- The system time is incorrect.

Solution

1. Obtain or import the CA certificate.
2. Use the **undo crl check enable** command to disable CRL checking, or obtain the correct CRL before you import certificates.
3. Make sure the format of the file to be imported is correct.
4. Make sure the certificate file contains the private key.
5. Make sure the certificate is not revoked.
6. Make sure the certificate is valid.
7. Configure the correct system time for the device.
8. If the problem persists, contact H3C Support.

Failed to export certificates

Symptom

Certificates cannot be exported.

Analysis

- The PKI domain does not have local certificates when you export all certificates in PKCS12 format.
- The specified export path does not exist.
- The specified export path is illegal.
- The public key of the local certificate to be exported does not match the public key of the key pair configured in the PKI domain.
- The storage space of the device is full.

Solution

1. Obtain or request local certificates first.
2. Use the **mkdir** command to create the required path.
3. Specify a correct export path.
4. Configure the correct key pair in the PKI domain.
5. Clear up the storage space of the device.
6. If the problem persists, contact H3C Support.

Failed to set the storage path

Symptom

The storage path for certificates or CRLs cannot be set.

Analysis

- The specified storage path does not exist.
- The specified storage path is illegal.
- The storage space of the device is full.

Solution

1. Use the **mkdir** command to create the path.
2. Specify a valid storage path for certificates or CRLs.
3. Clear up the storage space of the device.
4. If the problem persists, contact H3C Support.

Configuring IPsec

About IPsec

IP Security (IPsec) is defined by the IETF to provide interoperable, high-quality, cryptography-based security for IP communications. It is a Layer 3 VPN technology that transmits data in a secure channel established between two endpoints (such as two security gateways). Such a secure channel is usually called an IPsec tunnel.

IPsec framework

IPsec is a security framework that has the following protocols and algorithms:

- Authentication Header (AH).
- Encapsulating Security Payload (ESP).
- Internet Key Exchange (IKE).
- Algorithms for authentication and encryption.

AH and ESP are security protocols that provide security services. IKE performs automatic key exchange. For more information about IKE, see "Configuring IKE."

IPsec security services

IPsec provides the following security services for data packets in the IP layer:

- **Confidentiality**—The sender encrypts packets before transmitting them over the Internet, protecting the packets from being eavesdropped en route.
- **Data integrity**—The receiver verifies the packets received from the sender to make sure they are not tampered with during transmission.
- **Data origin authentication**—The receiver verifies the authenticity of the sender.
- **Anti-replay**—The receiver examines packets and drops outdated and duplicate packets.

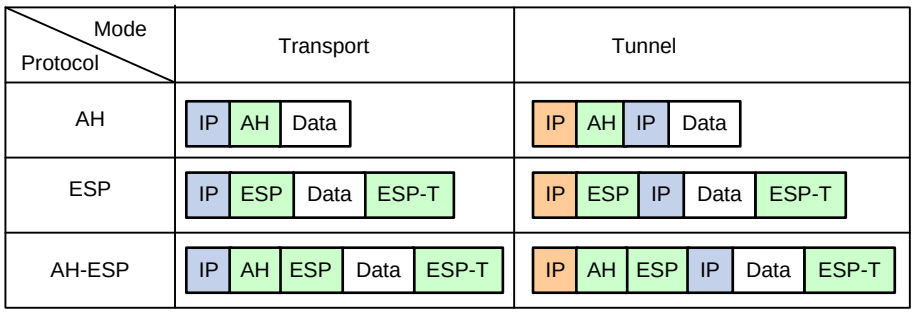
Benefits of IPsec

IPsec delivers the following benefits:

- Reduced key negotiation overhead and simplified maintenance by supporting the IKE protocol. IKE provides automatic key negotiation and automatic IPsec security association (SA) setup and maintenance.
- Good compatibility. You can apply IPsec to all IP-based application systems and services without modifying them.
- Encryption on a per-packet rather than per-flow basis. Per-packet encryption allows for flexibility and greatly enhances IP security.

Security protocols

IPsec comes with two security protocols, AH and ESP. They define how to encapsulate IP packets and the security services that they can provide.



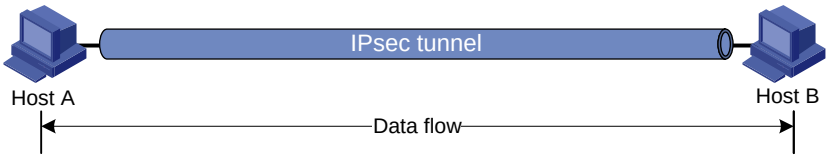
- AH (protocol 51) defines the encapsulation of the AH header in an IP packet, as shown in Figure 1. AH can provide data origin authentication, data integrity, and anti-replay services to

prevent data tampering, but it cannot prevent eavesdropping. Therefore, it is suitable for transmitting non-confidential data. The authentication algorithms supported by AH include HMAC-MD5 and HMAC-SHA1. AH does not support NAT traversal.

- ESP (protocol 50) defines the encapsulation of the ESP header and trailer in an IP packet, as shown in Figure 1. ESP can provide data encryption, data origin authentication, data integrity, and anti-replay services. Unlike AH, ESP can guarantee data confidentiality because it can encrypt the data before encapsulating the data to IP packets. ESP-supported encryption algorithms include DES, 3DES, and AES, and authentication algorithms include HMAC-MD5 and HMAC-SHA1.

Both AH and ESP provide authentication services, but the authentication service provided by AH is stronger. In practice, you can choose either or both security protocols. When both AH and ESP are used, an IP packet is encapsulated first by ESP and then by AH.

Figure 1 Security protocol encapsulations in different modes



Encapsulation modes

IPsec supports the following encapsulation modes: transport mode and tunnel mode.

Transport mode

The security protocols protect the upper layer data of an IP packet. Only the transport layer data is used to calculate the security protocol headers. The calculated security protocol headers and the encrypted data (only for ESP encapsulation) are placed after the original IP header. You can use the transport mode when end-to-end security protection is required (the secured transmission start and end points are the actual start and end points of the data). The transport mode is typically used for protecting host-to-host communications, as shown in Figure 2.

Figure 2 IPsec protection in transport mode

Tunnel mode

The security protocols protect the entire IP packet. The entire IP packet is used to calculate the security protocol headers. The calculated security protocol headers and the encrypted data (only for ESP encapsulation) are encapsulated in a new IP packet. In this mode, the encapsulated packet has two IP headers. The inner IP header is the original IP header. The outer IP header is added by the network device that provides the IPsec service. You must use the tunnel mode when the secured transmission start and end points are not the actual start and end points of the data packets (for example, when two gateways provide IPsec but the data start and end points are two hosts behind the gateways). The tunnel mode is typically used for protecting gateway-to-gateway communications, as shown in Figure 3.

Figure 3 IPsec protection in tunnel mode

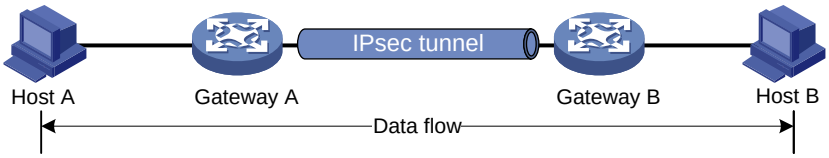


Figure 4 shows how the security protocols encapsulate an IP packet in different encapsulation modes.

Figure 4 Security protocol encapsulations in different modes

Mode / Protocol	Transport	Tunnel
AH	IP AH Data	IP AH IP Data
ESP	IP ESP Data ESP-T	IP ESP IP Data ESP-T
AH-ESP	IP AH ESP Data ESP-T	IP AH ESP IP Data ESP-T

Security association

A security association (SA) is an agreement negotiated between two communicating parties called IPsec peers. An SA includes the following parameters for data protection:

- Security protocols (AH, ESP, or both).
- Encapsulation mode (transport mode or tunnel mode).
- Authentication algorithm (HMAC-MD5 or HMAC-SHA1).
- Encryption algorithm (DES, 3DES, or AES).
- Shared keys and their lifetimes.

An SA is unidirectional. At least two SAs are needed to protect data flows in a bidirectional communication. If two peers want to use both AH and ESP to protect data flows between them, they construct an independent SA for each protocol in each direction.

An SA is uniquely identified by a triplet, which consists of the security parameter index (SPI), destination IP address, and security protocol identifier. An SPI is a 32-bit number. It is transmitted in the AH/ESP header.

An SA can be set up manually or through IKE.

- **Manual mode**—Configure all parameters for the SA through commands. This configuration mode is complex and does not support some advanced features (such as periodic key update), but it can implement IPsec without IKE. This mode is mainly used in small and static networks or when the number of IPsec peers in the network is small.
- **IKE negotiation mode**—The peers negotiate and maintain the SA through IKE. This configuration mode is simple and has good expansibility. As a best practice, set up SAs through IKE negotiations in medium- and large-scale dynamic networks.

A manually configured SA never ages out. An IKE-created SA has a lifetime, which comes in two types:

- **Time-based lifetime**—Defines how long the SA can be valid after it is created.
- **Traffic-based lifetime**—Defines the maximum traffic that the SA can process.

If both lifetime timers are configured for an SA, the SA becomes invalid when either of the lifetime timers expires. Before the SA expires, IKE negotiates a new SA, which takes over immediately after its creation.

Authentication and encryption

Authentication algorithms

IPsec uses hash algorithms to perform authentication. A hash algorithm produces a fixed-length digest for an arbitrary-length message. IPsec peers respectively calculate message digests for each packet. The receiver compares the local digest with that received from the sender. If the digests are identical, the receiver considers the packet intact and the sender's identity valid. IPsec uses the Hash-based Message Authentication Code (HMAC) based authentication algorithms, including HMAC-MD5 and HMAC-SHA1. Compared with HMAC-SHA1, HMAC-MD5 is faster but less secure.

Encryption algorithms

IPsec uses symmetric encryption algorithms, which encrypt and decrypt data by using the same keys. The following encryption algorithms are available for IPsec on the device:

- **DES**—Encrypts a 64-bit plaintext block with a 56-bit key. DES is the least secure but the fastest algorithm.
- **3DES**—Encrypts plaintext data with three 56-bit DES keys. The key length totals up to 168 bits. It provides moderate security strength and is slower than DES.
- **AES**—Encrypts plaintext data with a 128-bit, 192-bit, or 256-bit key. AES provides the highest security strength and is slower than 3DES.

IPsec-protected traffic

IPsec tunnels can protect the following types of traffic:

- Packets that match specific ACLs.
- Packets routed to a tunnel interface.
- Packets of IPv6 routing protocols.

Two peers use security policies (IPsec policies or IPsec profiles) to protect packets between them. A security policy defines the range of packets to be protected by IPsec and the security parameters used for the protection. For more information about IPsec policies and IPsec profiles, see "IPsec policy and IPsec profile."

The following information describes how IPsec protects packets:

- When an IPsec peer identifies the packets to be protected according to the security policy, it sets up an IPsec tunnel and sends the packet to the remote peer through the tunnel. The IPsec tunnel can be manually configured beforehand, or it can be set up through IKE negotiation triggered by the packet. The IPsec tunnels are actually the IPsec SAs. The inbound packets are protected by the inbound SA, and the outbound packets are protected by the outbound SA.
- When the remote IPsec peer receives the packet, it drops, de-encapsulates, or directly forwards the packet according to the configured security policy.

ACL-based IPsec

To implement ACL-based IPsec, configure an ACL to define the data flows to be protected, specify the ACL in an IPsec policy, and then apply the IPsec policy to an interface.

ACL-based IPsec works as follows:

- When packets sent by the interface match a permit rule of the ACL, the packets are protected by the outbound IPsec SA and encapsulated with IPsec.

- When the interface receives an IPsec packet destined for the local device, it searches for the inbound IPsec SA according to the SPI in the IPsec packet header for de-encapsulation. If the de-encapsulated packet matches a permit rule of the ACL, the device processes the packet. If the de-encapsulated packet does not match any permit rule of the ACL, the device drops the packet.

The device supports the following data flow protection modes:

- **Standard mode**—One IPsec tunnel protects one data flow. The data flow permitted by an ACL rule is protected by one IPsec tunnel that is established solely for it.
- **Aggregation mode**—One IPsec tunnel protects all data flows permitted by all the rules of an ACL. This mode is only used to communicate with old-version devices.
- **Per-host mode**—One IPsec tunnel protects one host-to-host data flow. One host-to-host data flow is identified by one ACL rule and protected by one IPsec tunnel established solely for it. This mode consumes more system resources when multiple data flows exist between two subnets to be protected.

IPv6 routing protocol-based IPsec

You can implement IPv6 routing protocol-based IPsec by binding an IPsec profile to an IPv6 routing protocol. All packets of the protocol are encapsulated with IPsec. Supported IPv6 routing protocols include OSPFv3, IPv6 BGP, and RIPng.

All packets of the applications that are not bound to IPsec and the IPsec packets that failed to be de-encapsulated are dropped.

In one-to-many communication scenarios, you must configure the IPsec SAs for an IPv6 routing protocol in manual mode because of the following reasons:

- The automatic key exchange mechanism protects communications between two points. In one-to-many communication scenarios, automatic key exchange cannot be implemented.
- One-to-many communication scenarios require that all the devices use the same SA parameters (SPI and key) to receive and send packets. IKE negotiated SAs cannot meet this requirement.

IPsec policy and IPsec profile

IPsec policies and IPsec profiles define the parameters used to establish IPsec tunnels between two peers and the range of packets to be protected.

IPsec policy

An IPsec policy is a set of IPsec policy entries that have the same name but different sequence numbers.

An IPsec policy contains the following settings:

- An ACL that defines the range of data flows to be protected.
- An IPsec transform set that defines the security parameters used for IPsec protection.
- IPsec SA establishment mode.

  IPsec SAs can be established through manual configuration or IKE negotiation.
- Local and remote IP addresses that define the start and end points of the IPsec tunnel.

In the same IPsec policy, an IPsec policy entry with a smaller sequence number has a higher priority. When sending a packet, the interface applied with an IPsec policy looks through the IPsec policy's entries in ascending order of sequence numbers. If the packet matches the ACL of an IPsec policy entry, the interface encapsulates the packet according to the IPsec policy entry. If no match is found, the interface sends the packet out without IPsec protection.

When the interface receives an IPsec packet destined for the local device, it searches for the inbound IPsec SA according to the SPI in the IPsec packet header for de-encapsulation. If the de-encapsulated packet matches a permit rule of the ACL, the device processes the packet. If the de-encapsulated packet does not match a permit rule of the ACL, the device drops the packet.

IPsec profile

An IPsec profile has similar settings as an IPsec policy. It is uniquely identified by a name and does not support ACL configuration.

IPsec profiles can be classified into the following types:

- **Manual IPsec profile**—A manual IPsec profile is used to protect IPv6 routing protocols. It specifies the IPsec transform set used for protecting data flows, and the SPIs and keys used by the SAs.
- **IKE-based IPsec profile**—An IKE-based IPsec profile is applied to tunnel interfaces to protect tunneled traffic. It specifies the IPsec transform sets used for protecting data flows, and the IKE profile used for IKE negotiation.

Protocols and standards

- RFC 2401, *Security Architecture for the Internet Protocol*
- RFC 2402, *IP Authentication Header*
- RFC 2406, *IP Encapsulating Security Payload*
- RFC 4552, *Authentication/Confidentiality for OSPFv3*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

Restrictions and guidelines: IPsec configuration

IPsec supports encrypting and decrypting only software forwarded packets on the control plane. It does not handle the data packets on the user plane. For more information about the control plane and user plane, see QoS configuration in *ACL and QoS Configuration Guide*.

Typically, IKE uses UDP port 500 for communication, and AH and ESP use the protocol numbers 51 and 50, respectively. Make sure traffic of these protocols is not denied on the interfaces with IKE or IPsec configured.

Implementing ACL-based IPsec

ACLs for IPsec take effect only on traffic that is generated by the device and traffic that is destined for the device. They do not take effect on traffic forwarded through the device. For example, an ACL-based IPsec tunnel can protect log messages the device sends to a log server, but it does not protect data flows and voice flows that are forwarded by the device.

ACL-based IPsec tasks at a glance

To configure ACL-based IPsec, perform the following tasks:

1. Configuring an ACL

2. Configuring an IPsec transform set
3. Configuring an IPsec policy

   Choose one of the following tasks:
   - Configuring a manual IPsec policy
   - Configuring an IKE-based IPsec policy
4. Applying an IPsec policy to an interface
5. (Optional.) Configuring accessibility features for ACL-based IPsec
   - Enabling ACL checking for de-encapsulated packets
   - Configuring IPsec anti-replay
   - Configuring IPsec anti-replay redundancy
   - Binding a source interface to an IPsec policy
   - Enabling QoS pre-classify
   - Configuring the DF bit of IPsec packets
   - Configuring IPsec RRI
   - Configuring the global IPsec SA lifetime and idle timeout
   - Configuring IPsec fragmentation
6. (Optional.) Configuring logging and SNMP notification for IPsec.
   - Configuring IPsec logging
   - Configuring SNMP notifications for IPsec

Configuring an ACL

IPsec uses ACLs to identify the traffic to be protected.

Keywords in ACL rules

An ACL is a collection of ACL rules. Each ACL rule is a deny or permit statement. A permit statement identifies a data flow protected by IPsec, and a deny statement identifies a data flow that is not protected by IPsec. IPsec compares a packet against the ACL rules and processes the packet according to the first rule it matches.

- Each ACL rule matches both the outbound traffic and the returned inbound traffic. Suppose there is a rule **rule 0 permit ip source 1.1.1.0 0.0.0.255 destination 2.2.2.0 0.0.0.255**. This rule matches both traffic from 1.1.1.0 to 2.2.2.0 and traffic from 2.2.2.0 to 1.1.1.0.
- In the outbound direction, if a permit statement is matched, IPsec considers that the packet requires protection and continues to process it. If a deny statement is matched or no match is found, IPsec considers that the packet does not require protection and delivers it to the next module.
- In the inbound direction:
  - Non-IPsec packets that match a permit statement are dropped.
  - IPsec packets destined for the device itself are de-encapsulated. By default, the de-encapsulated packets are compared against the ACL rules. Only those that match a permit statement are processed. Other packets are dropped. If ACL checking for de-encapsulated IPsec packets is disabled, the de-encapsulated packets are not compared against the ACL rules and are directly processed by other modules.

When defining ACL rules for IPsec, follow these guidelines:

- Permit only data flows that need to be protected and use the **any** keyword with caution. With the **any** keyword specified in a permit statement, all outbound traffic matching the permit statement will be protected by IPsec. All inbound IPsec packets matching the permit statement will be received and processed, but all inbound non-IPsec packets will be dropped. This will cause all the inbound traffic that does not need IPsec protection to be dropped.

- Avoid statement conflicts in the scope of IPsec policy entries. When creating a deny statement, be careful with its match scope and match order relative to permit statements. The policy entries in an IPsec policy have different match priorities. ACL rule conflicts between them are prone to cause mistreatment of packets. For example, when configuring a permit statement for an IPsec policy entry to protect an outbound traffic flow, you must avoid the situation that the traffic flow matches a deny statement in a higher priority IPsec policy entry. Otherwise, the packets will be sent out as normal packets. If they match a permit statement at the receiving end, they will be dropped by IPsec.

The following example shows how an improper statement causes unexpected packet dropping. Only the ACL-related configuration is presented.

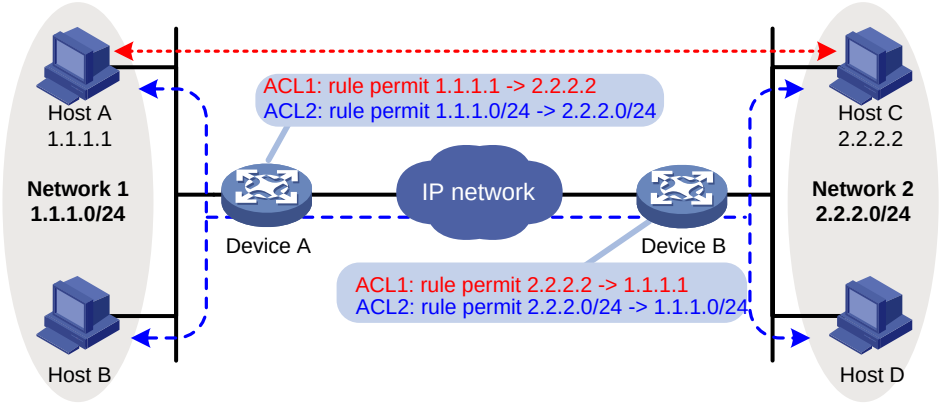
Assume Device A is connected to subnet 1.1.2.0/24 and Device B is connected to subnet 3.3.3.0/24, and the IPsec policy configuration on Device A and Device B is as follows:

- IPsec configuration on Device A:

```
acl advanced 3000
 rule 0 permit ip source 1.1.1.0 0.0.0.255 destination 2.2.2.0 0.0.0.255
 rule 1 deny ip
acl advanced 3001
 rule 0 permit ip source 1.1.2.0 0.0.0.255 destination 3.3.3.0 0.0.0.255
 rule 1 deny ip
#
ipsec policy testa 1 isakmp <---IPsec policy entry with a higher priority
 security acl 3000
 ike-profile aa
 transform-set 1
#
ipsec policy testa 2 isakmp <---IPsec policy entry with a lower priority
 security acl 3001
 ike-profile bb
 transform-set 1
```

- IPsec configuration on Device B:

```
acl advanced 3001
 rule 0 permit ip source 3.3.3.0 0.0.0.255 destination 1.1.2.0 0.0.0.255
 rule 1 deny ip
#
ipsec policy testb 1 isakmp
 security acl 3001
 ike-profile aa
 transform-set 1
```



On Device A, apply the IPsec policy **testa** to the outbound interface of Device A. The IPsec policy contains two policy entries, **testa 1** and **testa 2**. The ACLs used by the two policy entries each contain a rule that matches traffic from 1.1.2.0/24 to 3.3.3.0/24. The one used in the policy entry **testa 1** is a deny statement and the one used in the policy entry **testa 2** is a permit statement. Because **testa 1** is matched prior to **testa 2**, traffic from 1.1.2.0/24 to 3.3.3.0/24 will match the deny statement and be sent as normal traffic. When the traffic arrives at Device B, the traffic matches rule 0 (a permit statement) in ACL 3001 used in the applied IPsec policy **testb**. Because non-IPsec traffic that matches a permit statement must be dropped on the inbound interface, Device B drops the traffic.

To make sure subnet 1.1.2.0/24 can access subnet 3.3.3.0/24, you can delete the deny rule in ACL 3000 on Device A.

Mirror image ACLs

To make sure SAs can be set up and the traffic protected by IPsec can be processed correctly between two IPsec peers, create mirror image ACLs on the IPsec peers. As shown in Figure 5, ACL rules on Device B are mirror images of the rules on Device A. In this way, SAs can be created successfully for the traffic between Host A and Host C and for the traffic between Network 1 and Network 2.

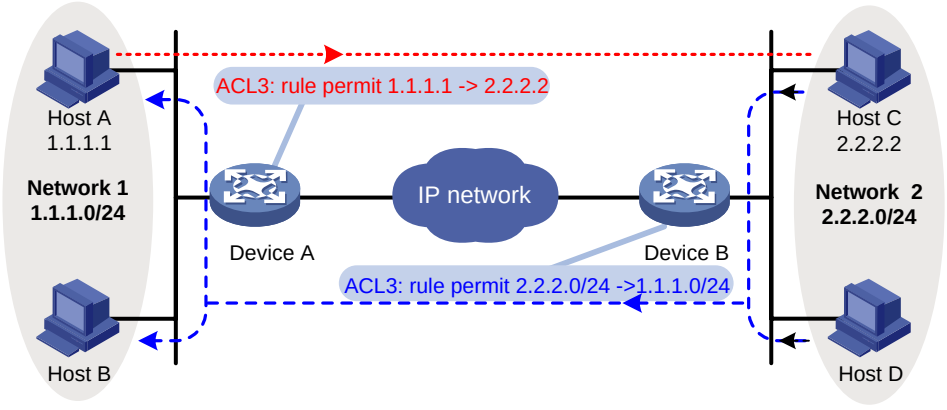


Figure 5 Mirror image ACLs

If the ACL rules on IPsec peers do not form mirror images of each other, SAs can be set up only when both of the following requirements are met:

- The range specified by an ACL rule on one peer is covered by its counterpart ACL rule on the other peer. As shown in Figure 6, the range specified by the ACL rule configured on Device A is covered by its counterpart on Device B.
- The peer with the narrower rule initiates SA negotiation. If a wider ACL rule is used by the SA initiator, the negotiation request might be rejected because the matching traffic is beyond the scope of the responder. As shown in Figure 6, the SA negotiation initiated by Host A to Host C is accepted but the SA negotiations from Host C to Host A, from Host C to Host B, and from Host D to Host A are rejected.

Figure 6 Non-mirror image ACLs

Configuring an IPsec transform set

About this task

An IPsec transform set, part of an IPsec policy, defines the security parameters for IPsec SA negotiation, including the security protocol, encryption algorithms, and authentication algorithms.

Restrictions and guidelines

Changes to an IPsec transform set affect only SAs negotiated after the changes. To apply the changes to existing SAs, execute the reset ipsec sa command to clear the SAs so that they can be set up by using the updated parameters.

In FIPS mode, you must specify both the ESP encryption algorithm and the ESP authentication algorithm for an IPsec transform set that uses the ESP security protocol.

When you set the packet encapsulation mode (tunnel or transport) for an IPsec transform set, follow these guidelines:

- The transport mode applies only when the source and destination IP addresses of data flows match those of the IPsec tunnel.
- IPsec for IPv6 routing protocols supports only the transport mode.

When you configure the Perfect Forward Secrecy (PFS) feature in an IPsec transform set, follow these guidelines:

- In IKEv1, the security level of the DH group of the initiator must be higher than or equal to that of the responder. This restriction does not apply to IKEv2.
- The end without the PFS feature performs SA negotiation according to the PFS requirements of the peer end.

You can specify multiple authentication or encryption algorithms for the same security protocol. The algorithm specified earlier has a higher priority.

Some algorithms are available only for IKEv2. See Table 1.

Table 1 Algorithms available only for IKEv2

Type	Algorithms
Encryption algorithm	aes-ctr-128 aes-ctr-192 aes-ctr-256 camellia-cbc-128 camellia-cbc-192 camellia-cbc-256 gmac-128 gmac-192 gmac-256 gcm-128 gcm-192 gcm-256
Authentication algorithm	aes-xcbc-mac

Procedure

1. Enter system view.
   system-view
2. Create an IPsec transform set and enter its view.
   ipsec transform-set *transform-set-name*
3. Specify the security protocol for the IPsec transform set.
   protocol { **ah** | **ah-esp** | **esp** }
   By default, the ESP security protocol is used.

4. Specify the encryption algorithms for ESP. Skip this step if the **protocol ah** command is configured.

   In non-FIPS mode:

   esp encryption-algorithm { **3des-cbc** | **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **aes-ctr-128** | **aes-ctr-192** | **aes-ctr-256** | **camellia-cbc-128** | **camellia-cbc-192** | **camellia-cbc-256** | **des-cbc** | **gmac-128** | **gmac-192** | **gmac-256** | **gcm-128** | **gcm-192** | **gcm-256** | **null** | **sm1-cbc-128** | **sm1-cbc-192** | **sm1-cbc-256** | **sm4-cbc** } *

   By default, no encryption algorithm is specified for ESP.

   In FIPS mode:

   esp encryption-algorithm { **gcm-128** | **gcm-192** | **gcm-256** } *

   By default, no encryption algorithm is specified for ESP.

5. Specify the authentication algorithms for ESP. Skip this step if the **protocol ah** command is configured.

   esp authentication-algorithm { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** | **sm3** } *

   By default, no authentication algorithm is specified for ESP.

   The **aes-xcbc-mac** algorithm is available only for IKEv2.

6. Specify the authentication algorithms for AH. Skip this step if the **protocol esp** command is configured.

   In non-FIPS mode:

   ah authentication-algorithm { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** | **sm3** } *

   By default, no authentication algorithm is specified for AH.

   The **aes-xcbc-mac** algorithm is available only for IKEv2.

   In FIPS mode:

   ah authentication-algorithm { **sha256** | **sha384** | **sha512** } *

   By default, no authentication algorithm is specified for AH.

7. Specify the packet encapsulation mode.

   encapsulation-mode { **transport** | **tunnel** }

   By default, the security protocol encapsulates IP packets in tunnel mode.

8. (Optional.) Enable the PFS feature.

   In non-FIPS mode:

   pfs { **dh-group1** | **dh-group2** | **dh-group5** | **dh-group14** | **dh-group24** | **dh-group19** | **dh-group20** }

   In FIPS mode:

   pfs { **dh-group19** | **dh-group20** | **dh-group24** }

   By default, the PFS feature is disabled.

   For more information about PFS, see "Configuring IKE."

9. (Optional.) Enable the Extended Sequence Number (ESN) feature.

   esn enable [**both**]

   By default, the ESN feature is disabled.

Configuring a manual IPsec policy

In a manual IPsec policy, the parameters are configured manually, such as the keys, the SPIs, and the IP addresses of the two ends in tunnel mode.

Restrictions and guidelines

When you configure a manual IPsec policy, make sure the IPsec configuration at both ends of the IPsec tunnel meets the following requirements:

- The IPsec policies at the two ends must have IPsec transform sets that use the same security protocols, security algorithms, and encapsulation mode.
- The remote IPv4 address configured on the local end must be the same as the primary IPv4 address of the interface applied with the IPsec policy at the remote end. The remote IPv6 address configured on the local end must be the same as the first IPv6 address of the interface applied with the IPsec policy at the remote end.
- At each end, configure parameters for both the inbound SA and the outbound SA, and make sure the SAs in each direction are unique: For an outbound SA, make sure its triplet (remote IP address, security protocol, and SPI) is unique. For an inbound SA, make sure its SPI is unique.
- The local inbound SA must use the same SPI and keys as the remote outbound SA. The same is true of the local outbound SA and remote inbound SA.
- The keys for the IPsec SAs at the two tunnel ends must be configured in the same format. For example, if the local end uses a key in hexadecimal format, the remote end must also use a key in hexadecimal format. If you configure a key in both the character and the hexadecimal formats, only the most recent configuration takes effect.
- If you configure a key in character format for ESP, the device automatically generates an authentication key and an encryption key for ESP.

Procedure

1. Enter system view.

   system-view

2. Create a manual IPsec policy entry and enter its view.

   ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* **manual**

3. (Optional.) Configure a description for the IPsec policy.

   description *text*

   By default, no description is configured.

4. Specify an ACL for the IPsec policy.

   security acl [**ipv6**] { *acl-number* | **name** *acl-name* }

   By default, no ACL is specified for an IPsec policy.

   You can specify only one ACL for an IPsec policy.

5. Specify an IPsec transform set for the IPsec policy.

   transform-set *transform-set-name*

   By default, no IPsec transform set is specified for an IPsec policy.

   You can specify only one IPsec transform set for a manual IPsec policy.

6. Specify the remote IP address of the IPsec tunnel.

   remote-address { *ipv4-address* | **ipv6** *ipv6-address* }

   By default, the remote IP address of the IPsec tunnel is not specified.

7. Configure an SPI for the inbound IPsec SA.

   sa spi inbound { **ah** | **esp** } *spi-number*

   By default, no SPI is configured for the inbound IPsec SA.

8. Configure an SPI for the outbound IPsec SA.

   sa spi outbound { **ah** | **esp** } *spi-number*

   By default, no SPI is configured for the outbound IPsec SA.

9. Configure keys for the IPsec SA.
   - Configure an authentication key in hexadecimal format for AH.

     sa hex-key authentication { **inbound** | **outbound** } **ah** { **cipher** | **simple** } *string*
   - Configure an authentication key in character format for AH.

     sa string-key { **inbound** | **outbound** } **ah** { **cipher** | **simple** } *string*
   - Configure a key in character format for ESP.

     sa string-key { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*
   - Configure an authentication key in hexadecimal format for ESP.

     sa hex-key authentication { **inbound** | **outbound** } **esp** { **cipher** | **simple** }
   - Configure an encryption key in hexadecimal format for ESP.

     sa hex-key encryption { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*

   By default, no keys are configured for the IPsec SA.

   Configure keys correctly for the security protocol (AH, ESP, or both) you have specified in the IPsec transform set used by the IPsec policy.

Configuring an IKE-based IPsec policy

About this task

In an IKE-based IPsec policy, the parameters are automatically negotiated through IKE.

To configure an IKE-based IPsec policy, use one of the following methods:

- Directly configure it by configuring the parameters in IPsec policy view.
- Configure it by using an existing IPsec policy template with the parameters to be negotiated configured.

  A device using an IPsec policy that is configured in this way cannot initiate an SA negotiation, but it can respond to a negotiation request. The parameters not defined in the template are determined by the initiator. For example, in an IPsec policy template, the ACL is optional. If you do not specify an ACL, the IPsec protection range has no limit. So the device accepts all ACL settings of the negotiation initiator.

  When the remote end's information (such as the IP address) is unknown, this method allows the remote end to initiate negotiations with the local end.

The configurable parameters for an IPsec policy template are the same as those when you directly configure an IKE-based IPsec policy. The difference is that more parameters are optional for an IPsec policy template. Except the IPsec transform sets and the IKE profile, all other parameters are optional.

Restrictions and guidelines for IKE-based IPsec policy configuration

The IPsec policies at the two tunnel ends must have IPsec transform sets that use the same security protocols, security algorithms, and encapsulation mode.

The IPsec policies at the two tunnel ends must have the same IKE profile parameters.

An IKE-based IPsec policy can use a maximum of six IPsec transform sets. During an IKE negotiation, IKE searches for a fully matched IPsec transform set at the two ends of the IPsec tunnel. If no match is found, no SA can be set up, and the packets expecting to be protected will be dropped.

The remote IP address of the IPsec tunnel is required on an IKE negotiation initiator and is optional on the responder. The remote IP address specified on the local end must be the same as the local IP address specified on the remote end.

The IPsec SA uses the local lifetime settings or those proposed by the peer, whichever are smaller.

The IPsec SA can have both a time-based lifetime and a traffic-based lifetime. The IPsec SA expires when either lifetime expires.

If you specify both an IKEv1 profile and an IKEv2 profile for an IPsec policy, the IKEv2 profile is used preferentially. For more information about IKEv1 and IKEv2 profiles, see "Configuring IKE" and "Configuring IKEv2."

Directly configuring an IKE-based IPsec policy

1. Enter system view.

   system-view

2. Create an IKE-based IPsec policy entry and enter its view.

   ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* **isakmp**

3. (Optional.) Configure a description for the IPsec policy.

   description *text*

   By default, no description is configured.

4. Specify an ACL for the IPsec policy.

   security acl [**ipv6**] { *acl-number* | **name** *acl-name* } [**aggregation** | **per-host**]

   By default, no ACL is specified for an IPsec policy.

   You can specify only one ACL for an IPsec policy.

5. Specify IPsec transform sets for the IPsec policy.

   transform-set *transform-set-name*&<1-6>

   By default, no IPsec transform sets are specified for an IPsec policy.

6. Specify an IKE profile or IKEv2 profile for the IPsec policy.
   - **Specify an IKE profile.**

     ike-profile *profile-name*

     By default, no IKE profile is specified for an IPsec policy.
   - **Specify an IKEv2 profile.**

     ikev2-profile *profile-name*

     By default, no IKEv2 profile is specified for an IPsec policy.

7. Specify the local IP address of the IPsec tunnel.

   local-address { *ipv4-address* | **ipv6** *ipv6-address* }

   By default, the local IPv4 address of the IPsec tunnel is the primary IPv4 address of the interface to which the IPsec policy is applied. The local IPv6 address of the IPsec tunnel is the first IPv6 address of the interface to which the IPsec policy is applied.

   The local IP address specified by this command must be the same as the IP address used as the local IKE identity.

   In a VRRP network, the local IP address must be the virtual IP address of the VRRP group to which the IPsec-applied interface belongs.

8. Specify the remote IP address of the IPsec tunnel.

   remote-address { [**ipv6**] *host-name* | *ipv4-address* | **ipv6** *ipv6-address* }

   By default, the remote IP address of the IPsec tunnel is not specified.

9. (Optional.) Set the lifetime or idle timeout for the IPsec SA.

- Set the IPsec SA lifetime.

  sa duration { **time-based** *seconds* | **traffic-based** *kilobytes* }

  By default, the global SA lifetime is used.
- Set the IPsec SA idle timeout.

  sa idle-time *seconds*

  By default, the global IPsec SA idle timeout is used.

10. (Optional.) Enable the Traffic Flow Confidentiality (TFC) padding feature.

tfc enable

By default, the TFC padding feature is disabled.

TFC padding applies only to IPsec SAs negotiated by IKEv2.

Configuring an IKE-based IPsec policy by using an IPsec policy template

1. Enter system view.

system-view

2. Create an IPsec policy template and enter its view.

ipsec { **ipv6-policy-template** | **policy-template** } *template-name seq-number*

3. (Optional.) Configure a description for the IPsec policy template.

description *text*

By default, no description is configured.

4. (Optional.) Specify an ACL for the IPsec policy template.

security acl [**ipv6**] { *acl-number* | **name** *acl-name* } [**aggregation** | **per-host**]

By default, no ACL is specified for an IPsec policy template.

You can specify only one ACL for an IPsec policy template.

5. Specify IPsec transform sets for the IPsec policy template.

transform-set *transform-set-name*&<1-6>

By default, no IPsec transform sets are specified for an IPsec policy template.

6. Specify an IKE profile or IKEv2 profile for the IPsec policy template.

- Specify an IKE profile.

  ike-profile *profile-name*

  By default, no IKE profile is specified for an IPsec policy template.

  Make sure the specified IKE profile is not used by another IPsec policy or IPsec policy template.
- Specify an IKEv2 profile.

  ikev2-profile *profile-name*

  By default, no IKEv2 profile is specified for an IPsec policy template.

7. Specify the local IP address of the IPsec tunnel.

local-address { *ipv4-address* | **ipv6** *ipv6-address* }

The default local IPv4 address and IPv6 address is the primary IPv4 address and first IPv6 address of the interface where the IPsec policy is applied.

The local IP address specified by this command must be the same as the IP address used as the local IKE identity.

In a VRRP network, the local IP address must be the virtual IP address of the VRRP group to which the IPsec-applied interface belongs.

8. Specify the remote IP address of the IPsec tunnel.

remote-address { [**ipv6**] *host-name* | *ipv4-address* | **ipv6** *ipv6-address* }

By default, the remote IP address of the IPsec tunnel is not specified.

9. (Optional.) Set the lifetime and idle timeout for the IPsec SA.
   - Set the IPsec SA lifetime.

     sa duration { **time-based** *seconds* | **traffic-based** *kilobytes* }

     By default, the global SA lifetime is used.
   - Set the IPsec SA idle timeout.

     sa idle-time *seconds*

     By default, the global IPsec SA idle timeout is used.
10. (Optional.) Enable the Traffic Flow Confidentiality (TFC) padding feature.

    tfc enable

    By default, the TFC padding feature is disabled.

    TFC padding applies only to IPsec SAs negotiated by IKEv2.
11. Return to system view.

    quit
12. Create an IPsec policy by using the IPsec policy template.

    ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* **isakmp template** *template-name*

Applying an IPsec policy to an interface

Restrictions and guidelines

You can apply an IPsec policy to interfaces to protect data flows.

- An IKE-based IPsec policy can be applied to multiple interfaces. As a best practice, apply an IKE-based IPsec policy to only one interface.
- A manual IPsec policy can be applied to only one interface.

To cancel the IPsec protection, remove the application of the IPsec policy.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Apply an IPsec policy to the interface.

   ipsec apply { **ipv6-policy** | **policy** } *policy-name*

   By default, no IPsec policy is applied to an interface.

   On one interface, you can apply a maximum of two IPsec policies: one IPv4 IPsec policy and one IPv6 IPsec policy.

   This feature is available only on Layer 3 interfaces.

   ○

Enabling ACL checking for de-encapsulated packets

About this task

This feature compares the de-encapsulated incoming IPsec packets against the ACL in the IPsec policy and discards those that do not match any permit rule of the ACL. This feature can protect networks against attacks using forged IPsec packets.

This feature applies only to tunnel-mode IPsec.

Procedure

1. Enter system view.
   system-view
2. Enable ACL checking for de-encapsulated packets.
   ipsec decrypt-check enable
   By default, ACL checking for de-encapsulated packets is enabled.

Configuring IPsec anti-replay

About this task

IPsec anti-replay protects networks against anti-replay attacks by using a sliding window mechanism called anti-replay window. This feature checks the sequence number of each received IPsec packet against the current IPsec packet sequence number range of the sliding window. If the sequence number is not in the current sequence number range, the packet is considered a replayed packet and is discarded.

IPsec packet de-encapsulation involves complicated calculation. De-encapsulation of replayed packets is not required, and the de-encapsulation process consumes large amounts of resources and degrades performance, resulting in DoS. IPsec anti-replay can check and discard replayed packets before de-encapsulation.

In some situations, service data packets are received in a different order than their original order. The IPsec anti-replay feature drops them as replayed packets, which impacts communications. If this happens, disable IPsec anti-replay checking or adjust the size of the anti-replay window as required.

Restrictions and guidelines

IPsec anti-replay does not affect manually created IPsec SAs. According to the IPsec protocol, only IKE-based IPsec SAs support anti-replay.

Set the anti-replay window size as small as possible to reduce the impact on system performance.

Failure to detect anti-replay attacks might result in denial of services. If you want to disable IPsec anti-replay, make sure you understand the impact of the operation on network security.

Procedure

1. Enter system view.
   system-view
2. Enable IPsec anti-replay.
   ipsec anti-replay check
   By default, IPsec anti-replay is enabled.
3. Set the size of the IPsec anti-replay window.
   ipsec anti-replay window *width*
   The default size is 64.

Configuring IPsec anti-replay redundancy

About this task

This feature synchronizes the following information from the active device to the standby device at configurable packet-based intervals:

- Lower bound values of the IPsec anti-replay window for inbound packets.
- IPsec anti-replay sequence numbers for outbound packets.

This feature, used together with IPsec redundancy, ensures uninterrupted IPsec traffic forwarding and anti-replay protection when the active device fails.

Procedure

1. Enter system view.

   system-view

2. Enable IPsec redundancy.

   ipsec redundancy enable

   By default, IPsec redundancy is disabled.

3. Enter IPsec policy view or IPsec policy template view.
   - Enter IPsec policy view.

     ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* [**isakmp** | **manual**]

   - Enter IPsec policy template view.

     ipsec { **ipv6-policy-template** | **policy-template** } *template-name seq-number*

4. Set the anti-replay window synchronization interval for inbound packets and the sequence number synchronization interval for outbound packets.

   redundancy replay-interval inbound *inbound-interval* **outbound** *outbound-interval*

   By default, the active device synchronizes the anti-replay window every time it receives 1000 packets and synchronizes the sequence number every time it sends 100000 packets.

Binding a source interface to an IPsec policy

About this task

For high availability, a core device is usually connected to an ISP through two links, which operate in backup or load sharing mode. The two interfaces negotiate with their peers to establish IPsec SAs respectively. When one interface fails and a link failover occurs, the other interface needs to take some time to renegotiate SAs, resulting in service interruption.

To solve these problems, bind a source interface to an IPsec policy and apply the policy to both interfaces. This enables the two physical interfaces to use the same source interface to negotiate IPsec SAs. As long as the source interface is up, the negotiated IPsec SAs will not be removed and will keep working, regardless of link failover.

Restrictions and guidelines

Only the IKE-based IPsec policies can be bound to a source interface.

An IPsec policy can be bound to only one source interface.

A source interface can be bound to multiple IPsec policies.

If the source interface bound to an IPsec policy is removed, the IPsec policy becomes a common IPsec policy.

If no local address is specified for an IPsec policy that has been bound to a source interface, the IPsec policy uses the IP address of the bound source interface to perform IKE negotiation. If a local address is specified, the IPsec policy uses the local address to perform IKE negotiation.

Procedure

1. Enter system view.

   system-view

2. Bind a source interface to an IPsec policy.

   ipsec { **ipv6-policy** | **policy** } *policy-name* **local-address** *interface-type interface-number*

   By default, no source interface is bound to an IPsec policy.

Enabling QoS pre-classify

About this task

When both an IPsec policy and a QoS policy are applied to an interface, QoS classifies packets by using the new headers added by IPsec. If you want QoS to classify packets by using the headers of the original IP packets, enable the QoS pre-classify feature.

Restrictions and guidelines

If you configure both IPsec and QoS on an interface, make sure the IPsec traffic classification rules match the QoS traffic classification rules. If the rules do not match, QoS might classify the packets of one IPsec SA to different queues, causing packets to be sent out of order. When IPsec anti-replay is enabled, IPsec will drop the incoming packets that are out of the anti-replay window, resulting in packet loss.

IPsec traffic classification rules are determined by the rules of the specified ACL. For more information about QoS policy and classification, see *ACL and QoS Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter IPsec policy view or IPsec policy template view.

   - Enter IPsec policy view.

     ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* [**isakmp** | **manual**]

   - Enter IPsec policy template view.

     ipsec { **ipv6-policy-template** | **policy-template** } *template-name seq-number*

3. Enable QoS pre-classify.

   qos pre-classify

   By default, QoS pre-classify is disabled.

Configuring the DF bit of IPsec packets

About this task

Perform this task to configure the Don't Fragment (DF) bit in the new IP header of IPsec packets in one of the following ways:

- **clear**—Clears the DF bit in the new header.
- **set**—Sets the DF bit in the new header.

- **copy**—Copies the DF bit in the original IP header to the new IP header.

You can configure the DF bit in system view and interface view. The interface-view DF bit setting takes precedence over the system-view DF bit setting. If the interface-view DF bit setting is not configured, the interface uses the system-view DF bit setting.

Restrictions and guidelines for DF bit configuration for IPsec packets

The DF bit setting takes effect only in tunnel mode, and it changes the DF bit in the new IP header rather than the original IP header.

This feature is available only on Layer 3 interfaces.

Configure the same DF bit setting on the interfaces where the same IPsec policy bound to a source interface is applied.

If the DF bit is set, the devices on the path cannot fragment the IPsec packets. To prevent IPsec packets from being discarded, make sure the path MTU is larger than the IPsec packet size. As a best practice, clear the DF bit if you cannot make sure the path MTU is larger than the IPsec packet size.

Configuring the DF bit of IPsec packets on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the DF bit of IPsec packets on the interface.
   ipsec df-bit { **clear** | **copy** | **set** }
   By default, the interface uses the global DF bit setting.

Configuring the DF bit of IPsec packets globally

1. Enter system view.
   system-view
2. Configure the DF bit of IPsec packets globally.
   ipsec global-df-bit { **clear** | **copy** | **set** }
   By default, IPsec copies the DF bit in the original IP header to the new IP header.

Configuring IPsec RRI

Restrictions and guidelines

Enabling IPsec RRI for an IPsec policy deletes all existing IPsec SAs created by this IPsec policy. IPsec RRI creates static routes according to new IPsec SAs.

Disabling IPsec RRI for an IPsec policy deletes all existing IPsec SAs created by this IPsec policy and the associated static routes.

IPsec RRI is supported in both tunnel mode and transport mode.

If you change the preference value or tag value for an IPsec policy, the device deletes all IPsec SAs created by this IPsec policy, and the associated static routes. The change takes effect for future IPsec RRI-created static routes.

IPsec RRI does not generate a static route to a destination address to be protected if the destination address is not defined in the ACL used by an IPsec policy or an IPsec policy template. You must manually configure a static route to the destination address.

Procedure

1. Enter system view.

system-view

2. Enter IPsec policy view or IPsec policy template view.
   - Enter IPsec policy view.
     ipsec { **policy** | **ipv6-policy** } *policy-name seq-number* **isakmp**
   - Enter IPsec policy template view.
     ipsec { **ipv6-policy-template** | **policy-template** } *template-name seq-number*
3. Enable IPsec RRI.
   reverse-route dynamic
   By default, IPsec RRI is disabled.
4. (Optional.) Set the preference value for the static routes created by IPsec RRI.
   reverse-route preference *number*
   The default value is 60.
5. (Optional.) Set the tag value for the static routes created by IPsec RRI.
   reverse-route tag *tag-value*
   The default value is 0.

Configuring IPsec for IPv6 routing protocols

IPsec protection for IPv6 routing protocols tasks at a glance

To configure IPsec protection for IPv6 routing protocols, perform the following tasks:

1. Configuring an IPsec transform set
2. Configuring a manual IPsec profile
3. Applying the IPsec profile to an IPv6 routing protocol
4. (Optional.) Configuring IPsec fragmentation
5. (Optional.) Configuring SNMP notifications for IPsec

Configuring a manual IPsec profile

About this task

A manual IPsec profile specifies the IPsec transform set used for protecting data flows, and the SPIs and keys used by the SAs.

Restrictions and guidelines

When you configure a manual IPsec profile, make sure the IPsec profile configuration at both tunnel ends meets the following requirements:

- The IPsec transform set specified in the IPsec profile at the two tunnel ends must have the same security protocol, encryption and authentication algorithms, and packet encapsulation mode.
- The local inbound and outbound IPsec SAs must have the same SPI and key.
- The IPsec SAs on the devices in the same scope must have the same key. The scope is defined by protocols. For OSPFv3, the scope consists of OSPFv3 neighbors or an OSPFv3 area. For RIPng, the scope consists of directly-connected neighbors or a RIPng process. For BGP, the scope consists of BGP peers or a BGP peer group.
- The keys for the IPsec SAs at the two tunnel ends must be configured in the same format. For example, if the local end uses a key in hexadecimal format, the remote end must also use a key

in hexadecimal format. If you configure a key in both the character and the hexadecimal formats, only the most recent configuration takes effect.

- If you configure a key in character format for ESP, the device automatically generates an authentication key and an encryption key for ESP.

Procedure

1. Enter system view.
   system-view
2. Create a manual IPsec profile and enter its view.
   ipsec profile *profile-name* **manual**
   The **manual** keyword is not needed if you enter the view of an existing IPsec profile.
3. (Optional.) Configure a description for the IPsec profile.
   description *text*
   By default, no description is configured.
4. Specify an IPsec transform set.
   transform-set *transform-set-name*
   By default, no IPsec transform set is specified in an IPsec profile.
   The specified IPsec transform set must use the transport mode.
5. Configure an SPI for an SA.
   sa spi { **inbound** | **outbound** } { **ah** | **esp** } *spi-number*
   By default, no SPI is configured for an SA.
6. Configure keys for the IPsec SA.
   - Configure an authentication key in hexadecimal format for AH.
     sa hex-key authentication { **inbound** | **outbound** } **ah** { **cipher** | **simple** } *string*
   - Configure an authentication key in character format for AH.
     sa string-key { **inbound** | **outbound** } **ah** { **cipher** | **simple** } *string*
   - Configure a key in character format for ESP.
     sa string-key { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*
   - Configure an authentication key in hexadecimal format for ESP.
     sa hex-key authentication { **inbound** | **outbound** } **esp** { **cipher** | **simple** }
   - Configure an encryption key in hexadecimal format for ESP.
     sa hex-key encryption { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*

   By default, no keys are configured for the IPsec SA.
   Configure a key for the security protocol (AH, ESP, or both) you have specified.

Applying the IPsec profile to an IPv6 routing protocol

For information about the configuration procedure, see IPv6 BGP, OSPFv3, and RIPng configuration in *Layer 3—IP Routing Configuration Guide*.

Configuring the global IPsec SA lifetime and idle timeout

About this task

If the IPsec SA lifetime and idle timeout are not configured in an IPsec policy, IPsec policy template, or IPsec profile, the global settings are used.

When IKE negotiates IPsec SAs, it uses the local lifetime settings or those proposed by the peer, whichever are smaller.

An IPsec SA can have both a time-based lifetime and a traffic-based lifetime. The IPsec SA expires when either lifetime expires.

Procedure

1. Enter system view.

   system-view
2. Set the global IPsec SA lifetime or idle timeout.
   - Set the global IPsec SA lifetime.

     ipsec sa global-duration { **time-based** *seconds* | **traffic-based** *kilobytes* }

     By default, the time-based SA lifetime is 3600 seconds, and the traffic-based SA lifetime is 1843200 kilobytes.
   - Set the global SA idle timeout.

     ipsec sa idle-time *seconds*

     By default, the global IPsec SA idle timeout feature is disabled.

Configuring IPsec fragmentation

About this task

Perform this task to configure the device to fragment packets before or after IPsec encapsulation.

If you configure the device to fragment packets before IPsec encapsulation, the device predetermines the encapsulated packet size before the actual encapsulation. If the encapsulated packet size exceeds the MTU of the output interface, the device fragments the packets before encapsulation. If a packet's DF bit is set, the device drops the packet and sends an ICMP error message.

If you configure the device to fragment packets after IPsec encapsulation, the device directly encapsulates the packets and fragments the encapsulated packets in subsequent service modules.

Restrictions and guidelines

This feature takes effect on IPsec protected IPv4 packets.

Procedure

1. Enter system view.

   system-view
2. Configure IPsec fragmentation.

   ipsec fragmentation { **after-encryption** | **before-encryption** }

   By default, the device fragments packets before IPsec encapsulation.

Setting the maximum number of IPsec tunnels

Restrictions and guidelines

To maximize concurrent performance of IPsec when memory is sufficient, increase the maximum number of IPsec tunnels. To ensure service availability when memory is insufficient, decrease the maximum number of IPsec tunnels.

Procedure

1. Enter system view.
   system-view
2. Set the maximum number of IPsec tunnels.
   ipsec limit max-tunnel *tunnel-limit*
   The number of IPsec tunnels is not limited.

Configuring IPsec logging

About this task

IPsec logging provides you with records of important IPsec configuration, negotiation, and packet events.

- After you enable configuration event logging, the device generates log entries when configuration events such as adding or deleting IPsec policies occur. A configuration event log entry primarily includes the name of the IPsec policy being configured, template number, and the number of IPsec policies that have been configured.
- After you enable negotiation logging, the device generates a log entry when negotiation succeeds or fails, for example, when IPsec SA creation succeeds or fails. A negotiation log entry primarily includes the source and destination IP addresses, SPI value, and sequence number of the negotiation packets. If the device drops a negotiation packet, the log entry also includes the reason for the packet drop.
- After you enable IPsec packet logging, the device generates a log entry when it drops a packet because of failure to find an inbound SA, AH or ESP authentication failure, ESP encryption failure, or any other issue. An IPsec packet log entry primarily includes the source and destination IP addresses, SPI value, and sequence number of the negotiation packets. If the device drops a negotiation packet, the log entry also includes the reason for the packet drop.

If you execute this command multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.
   system-view
2. Enable logging for IPsec packets.
   ipsec logging { **config** | **negotiation** | **packet** } **enable**
   By default, logging for IPsec packets is disabled.

Configuring SNMP notifications for IPsec

About this task

After you enable SNMP notifications for IPsec, the IPsec module notifies the NMS of important module events. The notifications are sent to the device's SNMP module. For the notifications to be

sent correctly, you must also configure SNMP on the device. For more information about SNMP notifications, see *Network Management and Monitoring Configuration Guide*.

To generate and output SNMP notifications for a specific IPsec failure or event type, perform the following tasks:

1. Enable SNMP notifications for IPsec globally.
2. Enable SNMP notifications for the failure or event type.

Procedure

1. Enter system view.

   system-view
2. Enable SNMP notifications for IPsec globally.

   snmp-agent trap enable ipsec global

   By default, SNMP notifications for IPsec are disabled.
3. Enable SNMP notifications for the specified failure or event types.

   snmp-agent trap enable ipsec [**auth-failure** | **decrypt-failure** | **encrypt-failure** | **invalid-sa-failure** | **no-sa-failure** | **policy-add** | **policy-attach** | **policy-delete** | **policy-detach** | **sa-establish** | **sa-establish-failure** | **sa-initiate** | **sa-terminate** | **tunnel-start** | **tunnel-stop**] *

   By default, SNMP notifications for all failure and event types are disabled.

Display and maintenance commands for IPsec

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display IPsec policy information.	**display ipsec** { **ipv6-policy** | **policy** } [*policy-name* [*seq-number*]]
Display IPsec policy template information.	**display ipsec** { **ipv6-policy-template** | **policy-template** } [*template-name* [*seq-number*]]
Display IPsec profile information.	**display ipsec profile** [*profile-name*]
Display IPsec SA information.	**display ipsec sa** [**brief** | **count** | **interface** *interface-type interface-number* | { **ipv6-policy** | **policy** } *policy-name* [*seq-number*] | **profile** *profile-name* | **remote** [**ipv6**] *ip-address*]
Display IPsec statistics.	**display ipsec statistics** [**tunnel-id** *tunnel-id*]
Display IPsec transform set information.	**display ipsec transform-set** [*transform-set-name*]
Display IPsec tunnel information.	**display ipsec tunnel** { **brief** | **count** | **tunnel-id** *tunnel-id* }

Task	Command
Clear IPsec SAs.	**reset ipsec sa** [{ **ipv6-policy** | **policy** } *policy-name* [*seq-number*] | **profile** *policy-name* | **remote** { *ipv4-address* | **ipv6** *ipv6-address* } | **spi** { *ipv4-address* | **ipv6** *ipv6-address* } { **ah** | **esp** } *spi-num*]
Clear IPsec statistics.	**reset ipsec statistics** [**tunnel-id** *tunnel-id*]

IPsec configuration examples

Example: Configuring a manual mode IPsec tunnel for IPv4 packets

Network configuration

As shown in Figure 7, establish an IPsec tunnel between Switch A and Switch B to protect data flows between the switches. Configure the tunnel as follows:

- Specify the encapsulation mode as tunnel, the security protocol as ESP, the encryption algorithm as AES-CBC-192, and the authentication algorithm as HMAC-SHA1.
- Manually set up IPsec SAs.

Figure 7 Network diagram

Procedure

1. Configure Switch A:

   # Assign IP addresses to interfaces, as shown in Figure 7.

   ```
   <Sysname> system-view
   [Sysname] sysname SwitchA
   [SwitchA] vlan 1
   [SwitchA-vlan1] quit
   [SwitchA] interface vlan-interface 1
   [SwitchA-Vlan-interface1] ip address 2.2.2.1 255.255.255.0
   [SwitchA-Vlan-interface1] quit
   [SwitchA] interface gigabitethernet 1/0/2
   [SwitchA-GigabitEthernet1/0/2] port access vlan 1
   [SwitchA-GigabitEthernet1/0/2] quit
   ```

   # Configure an IPv4 advanced ACL to identify the data flows between Switch A and Switch B.

   ```
   [SwitchA] acl advanced 3101
   [SwitchA-acl-ipv4-adv-3101] rule 0 permit ip source 2.2.2.1 0 destination 2.2.3.1 0
   [SwitchA-acl-ipv4-adv-3101] quit
   ```

   # Create an IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchA-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create a manual IPsec policy entry. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 manual
```

Specify ACL 3101.

```
[SwitchA-ipsec-policy-manual-map1-10] security acl 3101
```

Specify IPsec transform set **tran1**.

```
[SwitchA-ipsec-policy-manual-map1-10] transform-set tran1
```

Specify the remote IP address of the IPsec tunnel as 2.2.3.1.

```
[SwitchA-ipsec-policy-manual-map1-10] remote-address 2.2.3.1
```

Configure inbound and outbound SPIs for ESP.

```
[SwitchA-ipsec-policy-manual-map1-10] sa spi outbound esp 12345
[SwitchA-ipsec-policy-manual-map1-10] sa spi inbound esp 54321
```

Configure the inbound and outbound SA keys for ESP.

```
[SwitchA-ipsec-policy-manual-map1-10] sa string-key outbound esp simple abcdefg
[SwitchA-ipsec-policy-manual-map1-10] sa string-key inbound esp simple gfedcba
[SwitchA-ipsec-policy-manual-map1-10] quit
```

Apply IPsec policy **map1** to VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipsec apply policy map1
```

2. Configure Switch B:

Assign IP addresses to interfaces, as shown in Figure 7.

```
<Sysname> system-view
[Sysname] sysname SwitchB
[SwitchB] vlan 1
[SwitchB-vlan1] quit
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ip address 2.2.3.1 255.255.255.0
[SwitchB-Vlan-interface1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] port access vlan 1
[SwitchB-GigabitEthernet1/0/2] quit
```

Configure an IPv4 advanced ACL to identify the data flows between Switch B and Switch A.

```
[SwitchB] acl advanced 3101
[SwitchB-acl-ipv4-adv-3101] rule 0 permit ip source 2.2.3.1 0 destination 2.2.2.1 0
[SwitchB-acl-ipv4-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchB-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create a manual IPsec policy entry. Specify the policy name as **use1** and set the sequence number to 10.

```
[SwitchB] ipsec policy use1 10 manual
```

Specify ACL 3101.

```
[SwitchB-ipsec-policy-manual-use1-10] security acl 3101
```

Specify IPsec transform set **tran1**.

```
[SwitchB-ipsec-policy-manual-use1-10] transform-set tran1
```

Specify the remote IP address of the IPsec tunnel as 2.2.2.1.

```
[SwitchB-ipsec-policy-manual-use1-10] remote-address 2.2.2.1
```

Configure the inbound and outbound SPIs for ESP.

```
[SwitchB-ipsec-policy-manual-use1-10] sa spi outbound esp 54321
[SwitchB-ipsec-policy-manual-use1-10] sa spi inbound esp 12345
```

Configure the inbound and outbound SA keys for ESP.

```
[SwitchB-ipsec-policy-manual-use1-10] sa string-key outbound esp simple gfedcba
[SwitchB-ipsec-policy-manual-use1-10] sa string-key inbound esp simple abcdefg
[SwitchB-ipsec-policy-manual-use1-10] quit
```

Apply IPsec policy **use1** to VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ipsec apply policy use1
```

Verifying the configuration

After the configuration is completed, an IPsec tunnel between Switch A and Switch B is established, and the traffic between the switches is IPsec-protected. This example uses Switch A to verify the configuration.

Use the **display ipsec sa** command to display IPsec SAs on Switch A.

```
[SwitchA] display ipsec sa
-------------------------------
Interface: Vlan-interface 1
-------------------------------

  -----------------------------
  IPsec policy: map1
  Sequence number: 10
  Mode: manual
  -----------------------------
    Tunnel id: 549
    Encapsulation mode: tunnel
    Path MTU: 1443
    Tunnel:
        local  address: 2.2.2.1
        remote address: 2.2.3.1
```

```
    Flow:
        as defined in ACL 3101
    [Inbound ESP SA]
      SPI: 54321 (0x0000d431)
      Transform set: ESP-ENCRYPT-AES-CBC-192 ESP-AUTH-SHA1
      No duration limit for this SA
    [Outbound ESP SA]
      SPI: 12345 (0x00003039)
      Transform set: ESP-ENCRYPT-AES-CBC-192 ESP-AUTH-SHA1
      No duration limit for this SA
```

Example: Configuring an IKE-based IPsec tunnel for IPv4 packets

Network configuration

As shown in Figure 8, establish an IPsec tunnel between Switch A and Switch B to protect data flows between them. Configure the IPsec tunnel as follows:

- Specify the encapsulation mode as tunnel, the security protocol as ESP, the encryption algorithm as AES-CBC-192, and the authentication algorithm as HMAC-SHA1.
- Set up SAs through IKE negotiation.

Figure 8 Network diagram

Procedure

1. Configure Switch A:

Assign IP addresses to interfaces, as shown in Figure 8.

```
<Sysname> system-view
[Sysname] sysname SwitchA
[SwitchA] vlan 1
[SwitchA-vlan1] quit
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ip address 2.2.2.1 255.255.255.0
[SwitchA-Vlan-interface1] quit
[SwitchA] interface gigabitethernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] port access vlan 1
[SwitchA-GigabitEthernet1/0/2] quit
```

Configure an IPv4 advanced ACL to identify data flows from Switch A to Switch B.

```
[SwitchA] acl number 3101
[SwitchA-acl-adv-3101] rule 0 permit ip source 2.2.2.1 0 destination 2.2.3.1 0
[SwitchA-acl-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchA-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchA] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.3.1.

```
[SwitchA-ike-keychain-keychain1] pre-shared-key address 2.2.3.1 255.255.255.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchA-ike-keychain-keychain1] quit
```

Create and configure the IKE profile named **profile1**.

```
[SwitchA] ike profile profile1
[SwitchA-ike-profile-profile1] keychain keychain1
[SwitchA-ike-profile-profile1] match remote identity address 2.2.3.1 255.255.255.0
[SwitchA-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 isakmp
```

Apply ACL 3101.

```
[SwitchA-ipsec-policy-isakmp-map1-10] security acl 3101
```

Apply IPsec transform set **tran1**.

```
[SwitchA-ipsec-policy-isakmp-map1-10] transform-set tran1
```

Specify the local and remote IP addresses of the IPsec tunnel as 2.2.2.1 and 2.2.3.1.

```
[SwitchA-ipsec-policy-isakmp-map1-10] local-address 2.2.2.1
[SwitchA-ipsec-policy-isakmp-map1-10] remote-address 2.2.3.1
```

Apply IKE profile **profile1**.

```
[SwitchA-ipsec-policy-isakmp-map1-10] ike-profile profile1
[SwitchA-ipsec-policy-isakmp-map1-10] quit
```

Apply IPsec policy **map1** to VLAN interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipsec apply policy map1
```

2. Configure Switch B:

Assign IP addresses to interfaces, as shown in Figure 8.

```
<Sysname> system-view
[Sysname] sysname SwitchB
[SwitchB] vlan 1
[SwitchB-vlan1] quit
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ip address 2.2.3.1 255.255.255.0
[SwitchB-Vlan-interface1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] port access vlan 1
[SwitchB-GigabitEthernet1/0/2] quit
```

Configure an IPv4 advanced ACL to identify data flows from Switch B to Switch A.

```
[SwitchB] acl number 3101
[SwitchB-acl-adv-3101] rule 0 permit ip source 2.2.3.1 0 destination 2.2.2.1 0
[SwitchB-acl-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchB-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchB] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.2.1.

```
[SwitchB-ike-keychain-keychain1] pre-shared-key address 2.2.2.1 255.255.255.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchB-ike-keychain-keychain1] quit
```

Create and configure the IKE profile named **profile1**.

```
[SwitchB] ike profile profile1
[SwitchB-ike-profile-profile1] keychain keychain1
[SwitchB-ike-profile-profile1] match remote identity address 2.2.2.1 255.255.255.0
[SwitchB-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **use1** and set the sequence number to 10.

```
[SwitchB] ipsec policy use1 10 isakmp
```

Apply ACL 3101.

```
[SwitchB-ipsec-policy-isakmp-use1-10] security acl 3101
```

Apply IPsec transform set **tran1**.

```
[SwitchB-ipsec-policy-isakmp-use1-10] transform-set tran1
```

Specify the local and remote IP addresses of the IPsec tunnel as 2.2.3.1 and 2.2.2.1.

```
[SwitchB-ipsec-policy-isakmp-use1-10] local-address 2.2.3.1
[SwitchB-ipsec-policy-isakmp-use1-10] remote-address 2.2.2.1
```

Apply IKE profile **profile1**.

```
[SwitchB-ipsec-policy-isakmp-use1-10] ike-profile profile1
[SwitchB-ipsec-policy-isakmp-use1-10] quit
```

Apply IPsec policy **use1** to VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ipsec apply policy use1
```

Verifying the configuration

Initiate a connection between Switch A and Switch B to trigger IKE negotiation. After IPsec SAs are successfully negotiated by IKE, the traffic between the two switches is IPsec-protected.

Configuration files

Example: Configuring IPsec for RIPng

Network configuration

As shown in Figure 9, Switch A, Switch B, and Switch C learn IPv6 routes through RIPng.

Establish an IPsec tunnel between the switches to protect the RIPng packets transmitted in between. Specify the security protocol as ESP, the encryption algorithm as 128-bit AES, and the authentication algorithm as HMAC-SHA1 for the IPsec tunnel.

Figure 9 Network diagram

Requirements analysis

To meet the network configuration requirements, perform the following tasks:

1. Configure basic RIPng.

   For more information about RIPng configurations, see *Layer 3—IP Routing Configuration Guide*.

2. Configure an IPsec profile.
   - The IPsec profiles on all the switches must have IPsec transform sets that use the same security protocol, authentication and encryption algorithms, and encapsulation mode.
   - The SPI and key configured for the inbound SA and those for the outbound SA must be the same on each switch.
   - The SPI and key configured for the SAs on all the switches must be the same.
3. Apply the IPsec profile to a RIPng process or to an interface.

Procedure

1. Configure Switch A:

   # Assign IP addresses to interfaces,as shown in Figure 9.

```
<Sysname> system-view
[Sysname] sysname SwitchA
[SwitchA] vlan 100
[SwitchA-vlan100] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ipv6 address 1::1/64
[SwitchA-Vlan-interface100] quit
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] port access vlan 100
[SwitchA-GigabitEthernet1/0/1] quit
```

   # Configure basic RIPng.

```
[SwitchA] ripng 1
[SwitchA-ripng-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ripng 1 enable
[SwitchA-Vlan-interface100] quit
```

   # Create and configure the IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode transport
[SwitchA-ipsec-transform-set-tran1] protocol esp
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-128
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create and configure the IPsec profile named **profile001**.

```
[SwitchA] ipsec profile profile001 manual
[SwitchA-ipsec-profile-manual-profile001] transform-set tran1
[SwitchA-ipsec-profile-manual-profile001] sa spi outbound esp 123456
[SwitchA-ipsec-profile-manual-profile001] sa spi inbound esp 123456
[SwitchA-ipsec-profile-manual-profile001] sa string-key outbound esp simple abcdefg
[SwitchA-ipsec-profile-manual-profile001] sa string-key inbound esp simple abcdefg
[SwitchA-ipsec-profile-manual-profile001] quit
```

Apply the IPsec profile to RIPng process 1.

```
[SwitchA] ripng 1
[SwitchA-ripng-1] enable ipsec-profile profile001
[SwitchA-ripng-1] quit
```

2. Configure Switch B:

Assign IP addresses to interfaces,as shown in Figure 9.

```
<Sysname> system-view
[Sysname] sysname SwitchB
[SwitchB] vlan 100
[SwitchB-vlan100] quit
[SwitchB] vlan 200
[SwitchB-vlan200] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ipv6 address 3::1/64
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ipv6 address 1::2/64
[SwitchB-Vlan-interface100] quit
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port access vlan 100
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] port access vlan 200
[SwitchB-GigabitEthernet1/0/2] quit
```

Configure basic RIPng.

```
[SwitchB] ripng 1
[SwitchB-ripng-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ripng 1 enable
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ripng 1 enable
[SwitchB-Vlan-interface100] quit
```

Create and configure the IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode transport
[SwitchB-ipsec-transform-set-tran1] protocol esp
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-128
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create and configure the IPsec profile named **profile001**.

```
[SwitchB] ipsec profile profile001 manual
[SwitchB-ipsec-profile-manual-profile001] transform-set tran1
[SwitchB-ipsec-profile-manual-profile001] sa spi outbound esp 123456
[SwitchB-ipsec-profile-manual-profile001] sa spi inbound esp 123456
[SwitchB-ipsec-profile-manual-profile001] sa string-key outbound esp simple abcdefg
[SwitchB-ipsec-profile-manual-profile001] sa string-key inbound esp simple abcdefg
[SwitchB-ipsec-profile-manual-profile001] quit
```

Apply the IPsec profile to RIPng process 1.

```
[SwitchB] ripng 1
[SwitchB-ripng-1] enable ipsec-profile profile001
[SwitchB-ripng-1] quit
```

3. Configure Switch C:

Assign IP addresses to interfaces,as shown in Figure 9.

```
<Sysname> system-view
[Sysname] sysname SwitchC
[SwitchC] vlan 100
[SwitchC-vlan100] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] ipv6 address 3::2/64
[SwitchC-Vlan-interface200] quit
[SwitchC] interface gigabitethernet 1/0/1
[SwitchC-GigabitEthernet1/0/1] port access vlan 200
[SwitchC-GigabitEthernet1/0/1] quit
```

Configure basic RIPng.

```
[SwitchC] ripng 1
[SwitchC-ripng-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] ripng 1 enable
[SwitchC-Vlan-interface200] quit
```

Create and configure the IPsec transform set named **tran1**.

```
[SwitchC] ipsec transform-set tran1
[SwitchC-ipsec-transform-set-tran1] encapsulation-mode transport
[SwitchC-ipsec-transform-set-tran1] protocol esp
[SwitchC-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-128
[SwitchC-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchC-ipsec-transform-set-tran1] quit
```

Create and configure the IPsec profile named **profile001**.

```
[SwitchC] ipsec profile profile001 manual
[SwitchC-ipsec-profile-manual-profile001] transform-set tran1
[SwitchC-ipsec-profile-manual-profile001] sa spi outbound esp 123456
[SwitchC-ipsec-profile-manual-profile001] sa spi inbound esp 123456
[SwitchC-ipsec-profile-manual-profile001] sa string-key outbound esp simple abcdefg
```

```
[SwitchC-ipsec-profile-manual-profile001] sa string-key inbound esp simple abcdefg
[SwitchC-ipsec-profile-manual-profile001] quit
```

Apply the IPsec profile to RIPng process 1.

```
[SwitchC] ripng 1
[SwitchC-ripng-1] enable ipsec-profile profile001
[SwitchC-ripng-1] quit
```

Verifying the configuration

After the configuration is completed, Switch A, Switch B, and Switch C learn IPv6 routing information through RIPng. IPsec SAs are set up successfully on the switches to protect RIPng packets. This example uses Switch A to verify the configuration.

Display the RIPng configuration. The output shows that IPsec profile **profile001** has been applied to RIPng process 1.

```
[SwitchA] display ripng 1
    RIPng process : 1
       Preference : 100
       Checkzero : Enabled
       Default Cost : 0
       Maximum number of load balanced routes : 8
       Update time   :   30 secs  Timeout time         :  180 secs
       Suppress time :  120 secs  Garbage-Collect time :  120 secs
       Update output delay:   20(ms)  Output count:    3
       Graceful-restart interval:   60 secs
       Triggered Interval : 5 50 200
       Number of periodic updates sent : 186
       Number of triggered updates sent : 1
       IPsec profile name: profile001
```

Display the established IPsec SAs.

```
[SwitchA] display ipsec sa
------------------------------
Global IPsec SA
------------------------------

  ----------------------------
  IPsec profile: profile001
  Mode: Manual
  ----------------------------
    Encapsulation mode: transport
    [Inbound ESP SA]
      SPI: 123456 (0x3039)
      Connection ID: 90194313219
      Transform set: ESP-ENCRYPT-AES-CBC-128 ESP-AUTH-SHA1
      No duration limit for this SA
    [Outbound ESP SA]
      SPI: 123456 (0x3039)
      Connection ID: 64424509441
      Transform set: ESP-ENCRYPT-AES-CBC-128ESP-AUTH-SHA1
      No duration limit for this SA
```

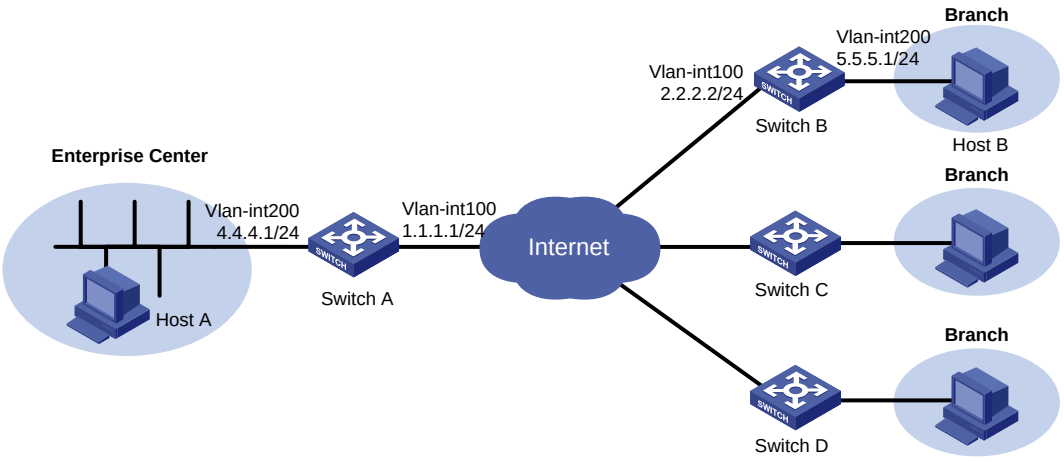
Example: Configuring IPsec RRI



Network configuration

As shown in Figure 10, branches access the enterprise center through an IPsec VPN.

Configure the IPsec VPN as follows:

- Configure an IPsec tunnel between Switch A and each branch gateway (Switch B, Switch C, and Switch D) to protect traffic between subnets 4.4.4.0/24 and 5.5.5.0/24.
- Configure the tunnels to use security protocol ESP, encryption algorithm DES, and authentication algorithm SHA1-HMAC-96. Use IKE for IPsec SA negotiation.
- Configure IKE proposal to use the preshared key authentication method, encryption algorithm 3DES, and authentication algorithm HMAC-SHA1.
- Configure IPsec RRI on Switch A to automatically create static routes to the branches based on the established IPsec SAs.

Figure 10 Network diagram

Procedure

1. Configure Switch A:

   # Assign IP addresses to interfaces, as shown in Figure 10.

```
<Sysname> system-view
[Sysname] sysname SwitchA
[SwitchA] vlan 100
[SwitchA-vlan100] quit
[SwitchA] vlan 200
[SwitchA-vlan200] quit
[SwitchA] interface vlan-interface 200
[SwitchA-Vlan-interface200] ip address 4.4.4.1 255.255.255.0
[SwitchA-Vlan-interface200] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ip address 1.1.1.1 255.255.255.0
[SwitchA-Vlan-interface100] quit
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] port access vlan 100
[SwitchA-GigabitEthernet1/0/1] quit
[SwitchA] interface gigabitethernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] port access vlan 200
[SwitchA-GigabitEthernet1/0/2] quit
```

Configure settings for routing. This example configures a static route, and the next hop in the route is 1.1.1.2.

```
[SwitchA] ip route-static 2.2.2.0 24 1.1.1.2
```

Create an IPsec transform set named **tran1**, and specify **ESP** as the security protocol, **DES** as the encryption algorithm, and **HMAC-SHA-1-96** as the authentication algorithm.

```
[SwitchA] ipsec transform-set tran1
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
[SwitchA-ipsec-transform-set-tran1] protocol esp
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm des
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create and configure the IKE profile named **profile1**.

```
[SwitchA] ike profile profile1
[SwitchA-ike-profile-profile1] keychain key1
[SwitchA-ike-profile-profile1] match remote identity address 2.2.2.2 255.255.255.0
[SwitchA-ike-profile-profile1] quit
```

Create an IPsec policy template named **temp1**. Specify IPsec transform set **tran1** and IKE profile **profile1** for the IPsec policy template.

```
[SwitchA] ipsec policy-template temp1 1
[SwitchA-ipsec-policy-template-temp1-1] transform-set tran1
[SwitchA-ipsec-policy-template-temp1-1] ike-profile profile1
```

Enable IPsec RRI, set the preference to 100 and the tag to 1000 for the static routes created by IPsec RRI.

```
[SwitchA-ipsec-policy-template-temp1-1] reverse-route dynamic
[SwitchA-ipsec-policy-template-temp1-1] reverse-route preference 100
[SwitchA-ipsec-policy-template-temp1-1] reverse-route tag 1000
[SwitchA-ipsec-policy-template-temp1-1] quit
```

Create an IKE-based IPsec policy entry by using IPsec policy template **temp1**. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 isakmp template temp1
```

Create an IKE proposal named **1**, and specify **3DES** as the encryption algorithm, **HMAC-SHA1** as the authentication algorithm, and **pre-share** as the authentication method.

```
[SwitchA] ike proposal 1
[SwitchA-ike-proposal-1] encryption-algorithm 3des-cbc
[SwitchA-ike-proposal-1] authentication-algorithm sha
[SwitchA-ike-proposal-1] authentication-method pre-share
[SwitchA-ike-proposal-1] quit
```

Create an IKE keychain named **key1** and specify **123** in plain text as the preshared key to be used with the remote peer at 2.2.2.2.

```
[SwitchA] ike keychain key1
[SwitchA-ike-keychain-key1] pre-shared-key address 2.2.2.2 key simple 123
[SwitchA-ike-keychain-key1] quit
```

Apply IPsec policy **map1** to VLAN-interface 100.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ipsec apply policy map1
[SwitchA-Vlan-interface100] quit
```

2. Configure Switch B:

Assign IP addresses to interfaces, as shown in Figure 10.

```
<Sysname> system-view
[Sysname] sysname SwitchB
[SwitchB] vlan 100
[SwitchB-vlan100] quit
[SwitchB] vlan 200
[SwitchB-vlan200] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ip address 5.5.5.1 255.255.255.0
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ip address 2.2.2.2 255.255.255.0
[SwitchB-Vlan-interface100] quit
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port access vlan 100
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] port access vlan 200
[SwitchB-GigabitEthernet1/0/2] quit
```

Configure static routes. In this example, the next hop in the routes is 2.2.2.3.

```
[SwitchB] ip route-static 1.1.1.0 24 2.2.2.3
[SwitchB] ip route-static 4.4.4.0 24 2.2.2.3
```

Create an IPsec transform set named **tran1**, and specify **ESP** as the security protocol, **DES** as the encryption algorithm, and **HMAC-SHA-1-96** as the authentication algorithm.

```
[SwitchB] ipsec transform-set tran1
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
[SwitchB-ipsec-transform-set-tran1] protocol esp
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm des
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Configure IPv4 advanced ACL 3000 to identify traffic from subnet 5.5.5.0/24 to subnet 4.4.4.0/24.

```
[SwitchB] acl advanced 3000
[SwitchB-acl-ipv4-adv-3000] rule permit ip source 5.5.5.0 0.0.0.255 destination 4.4.4.0 0.0.0.255
[SwitchB-acl-ipv4-adv-3000] quit
```

Create and configure the IKE profile named **profile1**.

```
[SwitchB] ike profile profile1
[SwitchB-ike-profile-profile1] keychain key1
[SwitchB-ike-profile-profile1] match remote identity address 1.1.1.1 255.255.255.0
[SwitchB-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry named **map1** and configure the following settings for the policy entry:

- Set the sequence number to 10.
- Specify transform set **tran1** and ACL 3000.
- Specify the remote IP address for the tunnel as 1.1.1.1.
- Specify IKE profile **profile1**.

```
[SwitchB] ipsec policy map1 10 isakmp
[SwitchB-ipsec-policy-isakmp-map1-10] transform-set tran1
[SwitchB-ipsec-policy-isakmp-map1-10] security acl 3000
[SwitchB-ipsec-policy-isakmp-map1-10] remote-address 1.1.1.1
[SwitchB-ipsec-policy-isakmp-map1-10] ike-profile profile1
[SwitchB-ipsec-policy-isakmp-map1-10] quit
```

Create an IKE proposal named **1**, and specify **3DES** as the encryption algorithm, **HMAC-SHA1** as the authentication algorithm, and **pre-share** as the authentication method.

```
[SwitchB] ike proposal 1
[SwitchB-ike-proposal-1] encryption-algorithm 3des-cbc
[SwitchB-ike-proposal-1] authentication-algorithm sha
[SwitchB-ike-proposal-1] authentication-method pre-share
[SwitchB-ike-proposal-1] quit
```

Create an IKE keychain named **key1** and specify **123** in plain text as the preshared key to be used with the remote peer at 1.1.1.1.

```
[SwitchB] ike keychain key1
[SwitchB-ike-keychain-key1] pre-shared-key address 1.1.1.1 key simple 123
[SwitchB-ike-keychain-key1] quit
```

Apply IPsec policy **map1** to VLAN-interface 100.

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ipsec apply policy map1
[SwitchB-Vlan-interface100] quit
```

Make sure Switch B has a route to the peer private network, with the outgoing interface as VLAN-interface 100.

3. Configure Switch C and Switch D in the same way Switch B is configured.

Verifying the configuration

1. Verify that IPsec RRI can automatically create a static route from Switch A to Switch B:

   # Initiate a connection from subnet 5.5.5.0/24 to subnet 4.4.4.0/24. IKE negotiation is triggered to establish IPsec SAs between Switch A and Switch B. (Details not shown.)

   # Verify that IPsec SAs are established on Switch A.

```
[SwitchA] display ipsec sa
```

```
------------------------------
Interface: Vlan-interface100
------------------------------

  ----------------------------
  IPsec policy: map1
  Sequence number: 10
  Mode: Template
  ----------------------------
    Tunnel id: 0
    Encapsulation mode: tunnel
    Perfect Forward Secrecy:
    Inside VPN:
    Extended Sequence Numbers enable: N
    Traffic Flow Confidentiality enable: N
    Path MTU: 1463
    Tunnel:
        local  address: 1.1.1.1
        remote address: 2.2.2.2
    Flow:
        sour addr: 4.4.4.0/255.255.255.0  port: 0  protocol: ip
        dest addr: 5.5.5.0/255.255.255.0  port: 0  protocol: ip

    [Inbound ESP SAs]
      SPI: 1014286405 (0x3c74c845)
      Connection ID: 90194313219
      Transform set: ESP-ENCRYPT-DES-CBC ESP-AUTH-SHA1
      SA duration (kilobytes/sec): 1843200/3600
      SA remaining duration (kilobytes/sec): 1843199/3590
      Max received sequence-number: 4
      Anti-replay check enable: Y
      Anti-replay window size: 64
      UDP encapsulation used for NAT traversal: N
      Status: Active

    [Outbound ESP SAs]
      SPI: 4011716027 (0xef1dedbb)
      Connection ID: 64424509441
      Transform set: ESP-ENCRYPT-DES-CBC ESP-AUTH-SHA1
      SA duration (kilobytes/sec): 1843200/3600
      SA remaining duration (kilobytes/sec): 1843199/3590
      Max sent sequence-number: 4
      UDP encapsulation used for NAT traversal: N
      Status: Active
```

Verify that IPsec RRI has created a static route to reach Switch B.

```
[SwitchA] display ip routing-table verbose
```

2. Verify that Switch A can automatically create static routes to Switch C and Switch D in the same way that you verify the IPsec RRI feature by using Switch A and Switch B. (Details not shown.)

Configuration files

Switch A

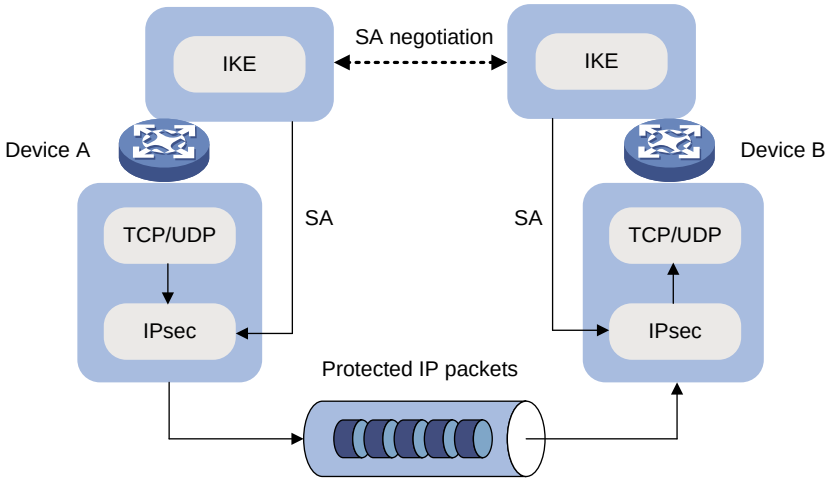
Configuring IKE

Unless otherwise specified, the term "IKE" in this chapter refers to IKEv1.

About IKE

Built on a framework defined by ISAKMP, Internet Key Exchange (IKE) provides automatic key negotiation and SA establishment services for IPsec.

Benefits of IKE



IKE provides the following benefits for IPsec:

- Automatically negotiates IPsec parameters.
- Performs DH exchanges to calculate shared keys, making sure each SA has a key that is independent of other keys.
- Automatically negotiates SAs when the sequence number in the AH or ESP header overflows, making sure IPsec can provide the anti-replay service by using the sequence number.

Relationship between IPsec and IKE

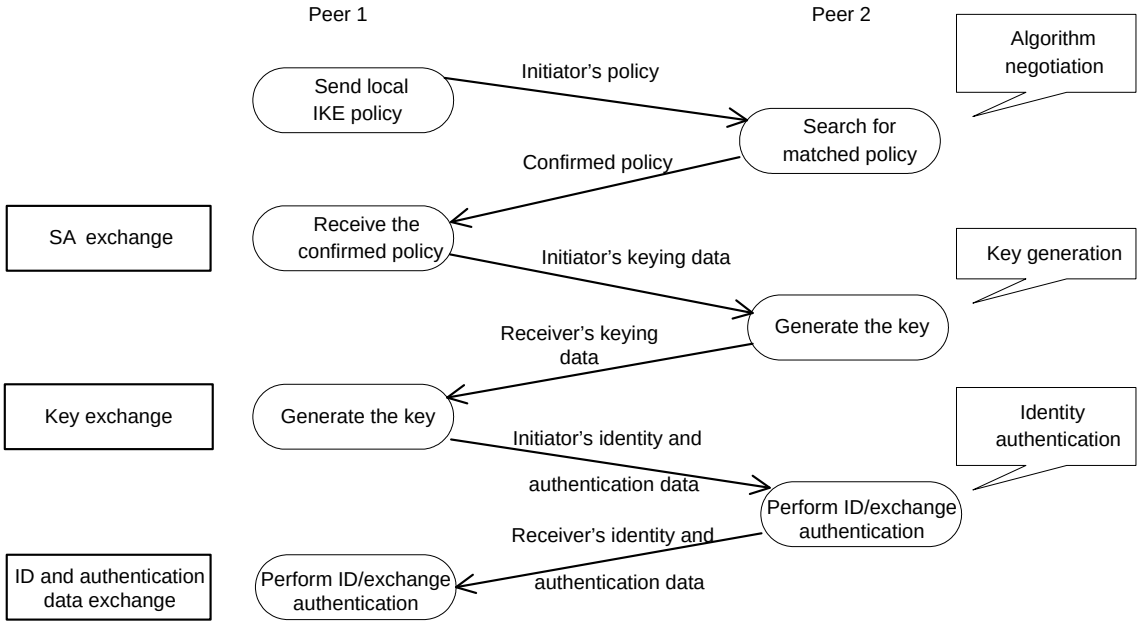
As shown in Figure 11, IKE negotiates SAs for IPsec and transfers the SAs to IPsec, and IPsec uses the SAs to protect IP packets.

Figure 11 Relationship between IKE and IPsec

IKE negotiation process

IKE negotiates keys and SAs for IPsec in two phases:

1. **Phase 1**—The two peers establish an IKE SA, a secure, authenticated channel for communication.
2. **Phase 2**—Using the IKE SA established in phase 1, the two peers negotiate to establish IPsec SAs.



Phase 1 negotiation can use either main mode or aggressive mode.

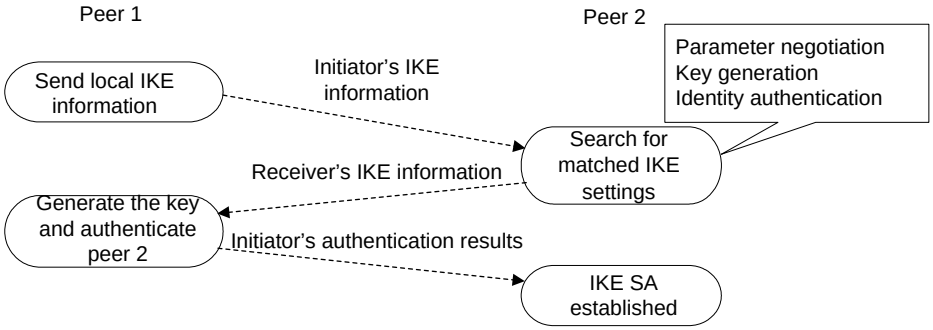
IKE exchange process in main mode

As shown in Figure 12, the main mode of IKE negotiation in phase 1 involves three pairs of messages:

- **SA exchange**—Used for negotiating the IKE security policy.
- **Key exchange**—Used for exchanging the DH public value and other values, such as the random number. The two peers use the exchanged data to generate key data and use the encryption key and authentication key to ensure the security of IP packets.
- **ID and authentication data exchange**—Used for identity authentication.

Figure 12 IKE exchange process in main mode

IKE exchange process in aggressive mode



As shown in Figure 13, the process of phase 1 IKE negotiation in aggressive mode is as follows:

1. The initiator (peer 1) sends a message containing the local IKE information to peer 2. The message includes parameters used for IKE SA establishment, keying data, and peer 1's identity information.
2. Peer 2 chooses the IKE establishment parameters to use, generate the key, and authenticate peer 1's identity. Then it sends the IKE data to peer 1.
3. Peer 1 generates the key, authenticates peer 2's identity, and sends the results to peer 1.

After the preceding process, an IKE SA is established between peer 1 and peer 2.

The aggressive mode is faster than the main mode but it does not provide identity information protection. The main mode provides identity information protection but is slower. Choose the appropriate negotiation mode according to your requirements.

Figure 13 IKE exchange process in aggressive mode

IKE security mechanism

IKE has a series of self-protection mechanisms and supports secure identity authentication, key distribution, and IPsec SA establishment on insecure networks.

Identity authentication

The IKE identity authentication mechanism is used to authenticate the identity of the communicating peers. The device supports the following identity authentication methods:

- **Preshared key authentication**—Two communicating peers use the pre-configured shared key for identity authentication.
- **RSA signature authentication** and **DSA signature authentication**—Two communicating peers use the digital certificates issued by the CA for identity authentication.

The preshared key authentication method does not require certificates and is easy to configure. It is usually deployed in small networks.

The signature authentication methods provide higher security and are usually deployed in networks with the headquarters and some branches. When deployed in a network with many branches, a signature authentication method can simplify the configuration because only one PKI domain is required. If you use the preshared key authentication method, you must configure a preshared key for each branch on the Headquarters node.

DH algorithm

The DH algorithm is a public key algorithm. With this algorithm, two peers can exchange keying material and then use the material to calculate the shared keys. Due to the decryption complexity, a third party cannot decrypt the keys even after intercepting all keying materials.

PFS

The Perfect Forward Secrecy (PFS) feature is a security feature based on the DH algorithm. After PFS is enabled, an additional DH exchange is performed in IKE phase 2 to make sure IPsec keys have no derivative relations with IKE keys and a broken key brings no threats to other keys.

Protocols and standards

- RFC 2408, *Internet Security Association and Key Management Protocol (ISAKMP)*
- RFC 2409, *The Internet Key Exchange (IKE)*
- RFC 2412, *The OAKLEY Key Determination Protocol*
- Internet Draft, *draft-ietf-ipsec-isakmp-xauth-06*
- Internet Draft, *draft-dukes-ike-mode-cfg-02*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

IKE tasks at a glance

To configure IKE, perform the following tasks:

1. (Optional.) Configuring an IKE profile
   a. Configuring an IKE profile
   b. Configuring peer IDs for the IKE profile
   c. Specifying the IKE keychain or PKI domain
   d. Configuring the IKE phase 1 negotiation mode
   e. Specifying IKE proposals for the IKE profile
   f. Configuring the local ID for the IKE profile
   g. Configuring optional features for the IKE profile
2. Configuring an IKE proposal
3. Configuring an IKE keychain
4. (Optional.) Configuring the global identity information
5. (Optional.) Configuring the IKE keepalive feature
6. (Optional.) Configuring the IKE NAT keepalive feature
7. (Optional.) Configuring global IKE DPD
8. (Optional.) Enabling invalid SPI recovery
9. (Optional.) Setting the maximum number of IKE SAs
10. (Optional.) Configuring an IKE IPv4 address pool
11. (Optional.) Configuring SNMP notifications for IKE

Prerequisites for IKE configuration

Determine the following parameters prior to IKE configuration:

- The algorithms to be used during IKE negotiation, including the identity authentication method, encryption algorithm, authentication algorithm, and DH group.
  - Different algorithms provide different levels of protection. A stronger algorithm provides more resistance to decryption but uses more resources.
  - A DH group that uses more bits provides higher security but needs more time for processing.
- The preshared key or PKI domain for IKE negotiation. For more information about PKI, see "Configuring PKI."
- The IKE-based IPsec policies for the communicating peers. If you do not specify an IKE profile in an IPsec policy, the device selects an IKE profile for the IPsec policy. If no IKE profile is configured, the globally configured IKE settings are used. For more information about IPsec, see "Configuring IPsec."

Configuring an IKE profile

Creating an IKE profile

About this task

Perform this task to create an IKE profile.

An IKE profile is intended to provide a set of parameters for IKE negotiation.

Procedure

1. Enter system view.
   system-view
2. Create an IKE profile and enter its view.
   ike profile *profile-name*

Configuring peer IDs for the IKE profile

About this task

Perform this task to configure the peer IDs for IKE profile matching. When the device needs to select an IKE profile for IKE negotiation with a peer, it compares the received peer ID with the peer IDs of its local IKE profiles. If a match is found, it uses the IKE profile with the matching peer ID for IKE negotiation.

Restrictions and guidelines

For an IKE profile, you can configure multiple peer IDs. A peer ID configured earlier has a higher priority.

Two IKE peers must both have or both not have peer IDs configured.

Procedure

1. Enter system view.
   system-view
2. Enter IKE profile view.
   ike profile *profile-name*
3. Configure a peer ID for the IKE profile.
   match remote { **certificate** *policy-name* | **identity** { **address** { { *ipv4-address* [*mask* | *mask-length*] | **range** *low-ipv4-address high-ipv4-address* } | **ipv6** { *ipv6-address* [*prefix-length*] | **range** *low-ipv6-address high-ipv6-address* } } [**vpn-instance** *vpn-instance-name*] | **fqdn** *fqdn-name* | **user-fqdn** *user-fqdn-name* } }

Specifying the IKE keychain or PKI domain

Restrictions and guidelines

Configure the IKE keychain or PKI domain for the IKE proposals to use. To use digital signature authentication, configure a PKI domain. To use preshared key authentication, configure an IKE keychain.

Procedure

1. Enter system view.

system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Specify the keychain for preshared key authentication or the PKI domain used to request a certificate for digital signature authentication.

   - Specify the keychain.

     keychain *keychain-name*

   - Specify the PKI domain.

     certificate domain *domain-name*

   By default, no IKE keychain or PKI domain is specified in an IKE profile.

Configuring the IKE phase 1 negotiation mode

Restrictions and guidelines

Specify the IKE phase 1 negotiation mode (main or aggressive) that the device uses as the initiator. When the device acts as the responder, it uses the IKE negotiation mode of the initiator.

Procedure

1. Enter system view.

   system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Specify the IKE negotiation mode for phase 1.

   In non-FIPS mode:

   exchange-mode { **aggressive** | **main** }

   In FIPS mode:

   exchange-mode main

   By default, IKE negotiation in phase 1 uses the main mode.

Specifying IKE proposals for the IKE profile

Restrictions and guidelines

Specify the IKE proposals that the device can use as the initiator. An IKE proposal specified earlier has a higher priority. When the device acts as the responder, it uses the IKE proposals configured in system view to match the IKE proposals received from the initiator. If no matching proposal is found, the negotiation fails.

Procedure

1. Enter system view.

   system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Specify IKE proposals for the IKE profile.

   proposal *proposal-number*&<1-6>

   By default, no IKE proposals are specified for an IKE profile and the IKE proposals configured in system view are used for IKE negotiation.

Configuring the local ID for the IKE profile

Restrictions and guidelines

For digital signature authentication, the device can use an ID of any type. If the local ID is an IP address that is different from the IP address in the local certificate, the device uses the FQDN (the device name configured by using the **sysname** command) instead.

For preshared key authentication, the device can use an ID of any type other than the DN.

Procedure

1. Enter system view.

   system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Configure the local ID.

   local-identity { **address** { *ipv4-address* | **ipv6** *ipv6-address* } | **dn** | **fqdn** [*fqdn-name*] | **user-fqdn** [*user-fqdn-name*] }

   By default, no local ID is configured for an IKE profile, and an IKE profile uses the local ID configured in system view. If the local ID is not configured in system view, the IKE profile uses the IP address of the interface to which the IPsec policy or IPsec policy template is applied as the local ID.

Configuring optional features for the IKE profile

1. Enter system view.

   system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Configure optional features as needed.

   - Configure IKE DPD.

     dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

     By default, IKE DPD is not configured for an IKE profile and an IKE profile uses the DPD settings configured in system view. If IKE DPD is not configured in system view either, the device does not perform dead IKE peer detection.

     The IKE DPD settings configured in the IKE profile view take precedence over those configured in system view.

   - Specify the local interface or IP address to which the IKE profile can be applied.

     match local address { *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] }

     By default, an IKE profile can be applied to any local interface or IP address.

     An IKE profile configured with this command has a higher priority over those not configured with this command.

   - Specify a priority for the IKE profile.

     priority *priority*

     By default, the priority of an IKE profile is 100.

     The device selects a local IKE profile for IKE negotiation as follows:

     – First, it selects an IKE profile with the **match local address** command configured.

- If a tie exists, it selects the IKE profile with a smaller priority number.
- If a tie still exists, it selects the IKE profile configured earlier.

- Enable client authentication.

  client-authentication xauth

  By default, client authentication is disabled.

  This feature is typically used on the IPsec gateway at the enterprise center. It enables the IPsec gateway to perform extended (XAUTH) authentication on remote users through AAA after IKE phase 1 negotiation. AAA configuration is also required on the IPsec gateway for client authentication.

- Enable AAA authorization.

  aaa authorization domain *domain-name* **username** *user-name*

  By default, AAA authorization is disabled.

  The AAA authorization feature enables IKE to request authorization attributes, such as the IKE IPv4 address pool, from AAA. IKE uses the address pool to assign IPv4 addresses to remote users. For more information about AAA authorization, see "Configuring AAA."

Configuring an IKE proposal

About this task

An IKE proposal defines a set of attributes describing how IKE negotiation in phase 1 should take place. You can create multiple IKE proposals with different priorities. The priority of an IKE proposal is represented by its sequence number. The lower the sequence number, the higher the priority.

Two peers must have at least one matching IKE proposal for successful IKE negotiation. During IKE negotiation:

- The initiator sends its IKE proposals to the peer.
  - If the initiator is using an IPsec policy with an IKE profile, the initiator sends all IKE proposals specified in the IKE profile to the peer. An IKE proposal specified earlier for the IKE profile has a higher priority.
  - If the initiator is using an IPsec policy with no IKE profile, the initiator sends all its IKE proposals to the peer. An IKE proposal with a smaller number has a higher priority.
- The peer searches its own IKE proposals for a match. The search starts from the IKE proposal with the highest priority and proceeds in descending order of priority until a match is found. The matching IKE proposals are used to establish the IKE SA. If all user-defined IKE proposals are found mismatching, the two peers use their default IKE proposals to establish the IKE SA.

Two matching IKE proposals have the same encryption algorithm, authentication method, authentication algorithm, and DH group. The SA lifetime takes the smaller one of the two proposals' SA lifetime settings.

Procedure

1. Enter system view.

   system-view

2. Create an IKE proposal and enter its view.

   ike proposal *proposal-number*

   By default, a default IKE proposal exists.

3. Configure a description for the IKE proposal.

   description

   By default, an IKE proposal does not have a description.

4. Specify an encryption algorithm for the IKE proposal.

In non-FIPS mode:

encryption-algorithm { **3des-cbc** | **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **des-cbc** | **sm1-cbc-128** | **sm1-cbc-192** | **sm1-cbc-256** | **sm4-cbc** }

By default, the 56-bit DES encryption algorithm in CBC mode is used .

In FIPS mode:

encryption-algorithm { **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** }

By default, the 128-bit AES encryption algorithm in CBC mode is used.

5. Specify an authentication method for the IKE proposal.

   In non-FIPS mode:

   authentication-method { **dsa-signature** | **ecdsa-signature** | **pre-share** | **rsa-signature** }

   In FIPS mode:

   authentication-method { **ecdsa-signature** | **pre-share** | **rsa-signature** }

   By default, the preshared key authentication method is used.

6. Specify an authentication algorithm for the IKE proposal.

   authentication-algorithm { **md5** | **sha** | **sha256** | **sha384** | **sha512** | **sm3** }

   By default, the HMAC-SHA1 authentication algorithm is used.

7. Specify a DH group for key negotiation in phase 1.

   In non-FIPS mode:

   dh { **group1** | **group14** | **group19** | **group2** | **group20** | **group24** | **group5** }

   DH group 1 (the 768-bit DH group) is used by default.

   In FIPS mode:

   dh { **group14** | **group19** | **group20** | **group24** }

   DH group 14 (the 2048-bit DH group) is used by default.

8. (Optional.) Set the IKE SA lifetime for the IKE proposal.

   sa duration *seconds*

   By default, the IKE SA lifetime is 86400 seconds.

Configuring an IKE keychain

About this task

Perform this task when you configure the IKE to use the preshared key for authentication.

Follow these guidelines when you configure an IKE keychain:

- Two peers must be configured with the same preshared key to pass preshared key authentication.
- You can specify the local address configured in IPsec policy or IPsec policy template view (using the **local-address** command) for the IKE keychain to be applied. If no local address is configured, specify the IP address of the interface that uses the IPsec policy.
- The device determines the priority of an IKE keychain as follows:
  a. The device examines the existence of the **match local address** command. An IKE keychain with the **match local address** command configured has a higher priority.
  b. If a tie exists, the device compares the priority numbers. An IKE keychain with a smaller priority number has a higher priority.
  c. If a tie still exists, the device prefers an IKE keychain configured earlier.

Procedure

1. Enter system view.

   system-view

2. Create an IKE keychain and enter its view.

   ike keychain *keychain-name* [**vpn-instance** *vpn-instance-name*]

3. Configure a preshared key.

   In non-FIPS mode:

   pre-shared-key { **address** { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] } | **hostname** *host-name* } **key** { **cipher** | **simple** } *string*

   In FIPS mode:

   pre-shared-key { **address** { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] } | **hostname** *host-name* } **key** [**cipher** *string*]

   By default, no preshared key is configured.

4. (Optional.) Specify a local interface or IP address to which the IKE keychain can be applied.

   match local address { *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] }

   By default, an IKE keychain can be applied to any local interface or IP address.

5. (Optional.) Specify a priority for the IKE keychain.

   priority *priority*

   The default priority is 100.

Configuring the global identity information

Restrictions and guidelines

The global identity can be used by the device for all IKE SA negotiations, and the local identity (set by the **local-identity** command) can be used only by the device that uses the IKE profile.

When signature authentication is used, you can set any type of the identity information.

When preshared key authentication is used, you cannot set the DN as the identity.

Procedure

1. Enter system view.

   system-view

2. Configure the global identity to be used by the local end.

   ike identity { **address** { *ipv4-address* | **ipv6** *ipv6-address* }| **dn** | **fqdn** [*fqdn-name*] | **user-fqdn** [*user-fqdn-name*] }

   By default, the IP address of the interface to which the IPsec policy or IPsec policy template is applied is used as the IKE identity.

3. (Optional.) Configure the local device to always obtain the identity information from the local certificate for signature authentication.

   ike signature-identity from-certificate

   By default, the local end uses the identity information specified by **local-identity** or **ike identity** for signature authentication.

Configure this command when the aggressive mode and signature authentication are used and the device interconnects with a Comware 5-based peer device. Comware 5 supports only DN for signature authentication.

Configuring the IKE keepalive feature

About this task

IKE sends keepalive packets to query the liveness of the peer. If the peer is configured with the keepalive timeout time, you must configure the keepalive interval on the local device. If the peer receives no keepalive packets during the timeout time, the IKE SA is deleted along with the IPsec SAs it negotiated.

Restrictions and guidelines

Configure IKE DPD instead of IKE keepalive unless IKE DPD is not supported on the peer. The IKE keepalive feature sends keepalives at regular intervals, which consumes network bandwidth and resources.

The keepalive timeout time configured on the local device must be longer than the keepalive interval configured at the peer. Since it seldom occurs that more than three consecutive packets are lost on a network, you can set the keepalive timeout three times as long as the keepalive interval.

Procedure

1. Enter system view.
   `system-view`
2. Set the IKE SA keepalive interval.
   `ike keepalive interval` *`interval`*
   By default, no keepalives are sent to the peer.
3. Set the IKE SA keepalive timeout time.
   `ike keepalive timeout` *`seconds`*
   By default, IKE SA keepalive never times out.

Configuring the IKE NAT keepalive feature

About this task

If IPsec traffic passes through a NAT device, you must configure the NAT traversal feature. If no packet travels across an IPsec tunnel in a period of time, the NAT sessions are aged and deleted, disabling the tunnel from transmitting data to the intended end. To prevent NAT sessions from being aged, configure the NAT keepalive feature on the IKE gateway behind the NAT device to send NAT keepalive packets to its peer periodically to keep the NAT session alive.

Procedure

1. Enter system view.
   `system-view`
2. Set the IKE NAT keepalive interval.
   `ike nat-keepalive` *`seconds`*
   The default interval is 20 seconds.

Configuring global IKE DPD

About this task

DPD detects dead peers. It can operate in periodic mode or on-demand mode.

- **Periodic DPD**—Sends a DPD message at regular intervals. It features an earlier detection of dead peers, but consumes more bandwidth and CPU.
- **On-demand DPD**—Sends a DPD message based on traffic. When the device has traffic to send and is not aware of the liveness of the peer, it sends a DPD message to query the status of the peer. If the device has no traffic to send, it never sends DPD messages. As a best practice, use the on-demand mode.

The IKE DPD works as follows:

1. The local device sends a DPD message to the peer, and waits for a response from the peer.
2. If the peer does not respond within the retry interval specified by the **retry** *seconds* parameter, the local device resends the message.
3. If still no response is received within the retry interval, the local end sends the DPD message again. The system allows a maximum of four retries.
4. If the local device receives no response after two retries, the device considers the peer to be dead, and deletes the IKE SA along with the IPsec SAs it negotiated.
5. If the local device receives a response from the peer during the detection process, the peer is considered alive. The local device performs a DPD detection again when the triggering interval is reached or it has traffic to send, depending on the DPD mode.

Restrictions and guidelines

When DPD settings are configured in both IKE profile view and system view, the DPD settings in IKE profile view apply. If DPD is not configured in IKE profile view, the DPD settings in system view apply.

It is a good practice to set the triggering interval longer than the retry interval so that a DPD detection is not triggered during a DPD retry.

Procedure

1. Enter system view.

   system-view

2. Enable sending IKE DPD messages.

   ike dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

   By default, IKE DPD is disabled.

Enabling invalid SPI recovery

About this task

An IPsec "black hole" occurs when one IPsec peer fails (for example, a peer can fail if a reboot occurs). One peer fails and loses its SAs with the other peer. When an IPsec peer receives a data packet for which it cannot find an SA, an invalid SPI is encountered. The peer drops the data packet and tries to send an SPI invalid notification to the data originator. This notification is sent by using the IKE SA. Because no IKE SA is available, the notification is not sent. The originating peer continues sending the data by using the IPsec SA that has the invalid SPI, and the receiving peer keeps dropping the traffic.

The invalid SPI recovery feature enables the receiving peer to set up an IKE SA with the originator so that an SPI invalid notification can be sent. Upon receiving the notification, the originating peer deletes the IPsec SA that has the invalid SPI. If the originator has data to send, new SAs will be set up.

Restrictions and guidelines

Use caution when you enable the invalid SPI recovery feature because using this feature can result in a DoS attack. Attackers can make a great number of invalid SPI notifications to the same peer.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable invalid SPI recovery.
   ```
   ike invalid-spi-recovery enable
   ```
   By default, the invalid SPI recovery is disabled.

Setting the maximum number of IKE SAs

About this task

You can set the maximum number of half-open IKE SAs and the maximum number of established IKE SAs.

- The supported maximum number of half-open IKE SAs depends on the device's processing capability. Adjust the maximum number of half-open IKE SAs to make full use of the device's processing capability without affecting the IKE SA negotiation efficiency.
- The supported maximum number of established IKE SAs depends on the device's memory space. Adjust the maximum number of established IKE SAs to make full use of the device's memory space without affecting other applications in the system.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Set the maximum number of half-open IKE SAs and the maximum number of established IKE SAs.
   ```
   ike limit { max-negotiating-sa negotiation-limit | max-sa sa-limit }
   ```
   By default, there is no limit to the maximum number of IKE SAs.

Configuring an IKE IPv4 address pool

About this task

To perform centralized management on remote users, an IPsec gateway can use an IPv4 address pool to assign private IPv4 addresses to remote users.

You must use an IKE IPv4 address pool together with AAA authorization by specifying the IKE IPv4 address pool as an AAA authorization attribute. For more information about AAA authorization, see "Configuring AAA."

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Configure an IKE IPv4 address pool.
   ```
   ike address-group group-name start-ipv4-address end-ipv4-address
   [ mask | mask-length ]
   ```

Configuring IKE logging

About this task

IKE logging provides you with records of important IKE configuration and negotiation events.

- IKE negotiation event logging generates log entries at the beginning and end of IKE negotiation phases and during key exchange and security parameters negotiation. An IKE negotiation event log entry primarily includes the source and destination IP addresses, source and destination ports, and initiator and responder. If the negotiation fails, the log entry also includes the reason for negotiation failure.
- IKE configuration event logging primarily records IKE proposal creation and deletion events. An IKE configuration log entry primarily includes proposal number information.

If you execute this command multiple times, the most recent configuration takes effect.

Restrictions and guidelines

This command is not available in FIPS mode.

Procedure

1. Enter system view.

   system-view
2. Enable IKE logging for event types of interest.

   ike logging { **config** | **negotiation** } * **enable**

   By default, IKE logging is disabled.

Configuring SNMP notifications for IKE

About this task

After you enable SNMP notifications for IKE, the IKE module notifies the NMS of important module events. The notifications are sent to the device's SNMP module. For the notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP notifications, see *Network Management and Monitoring Configuration Guide*.

To generate and output SNMP notifications for a specific IKE failure or event type, perform the following tasks:

1. Enable SNMP notifications for IKE globally.
2. Enable SNMP notifications for the failure or event type.

Procedure

1. Enter system view

   system-view
2. Enable SNMP notifications for IKE globally.

   snmp-agent trap enable ike global

   By default, SNMP notifications for IKE are disabled.
3. Enable SNMP notifications for the specified failure or event types.

   snmp-agent trap enable ike [**attr-not-support** | **auth-failure** | **cert-type-unsupport** | **cert-unavailable** | **cert-verify-failure** | **decrypt-failure** | **encrypt-failure** | **invalid-cert-auth** | **invalid-cookie** | **invalid-id** | **invalid-proposal** | **invalid-protocol** | **invalid-sign** | **no-sa-failure** | **p1sa-failure** | **p2sa-failure** |

p2sa-terminate | **proposal-add** | **proposal-delete** | **tunnel-start** | **tunnel-stop** | **unsupport-exch-type**] *

By default, SNMP notifications for all failure and event types are disabled.

Display and maintenance commands for IKE

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display configuration information about all IKE proposals.	**display ike proposal**
Display information about the current IKE SAs.	**display ike sa** [**verbose** [**connection-id** *connection-id*	**remote-address** [**ipv6**] *remote-address* [**vpn-instance** *vpn-instance-name*]]]
Display IKE statistics.	**display ike statistics**
Delete IKE SAs.	**reset ike sa** [**connection-id** *connection-id*]
Clear IKE MIB statistics.	**reset ike statistics**

IKE configuration examples

Example: Configuring main-mode IKE with preshared key authentication

Network configuration

As shown in Figure 14, configure an IKE-based IPsec tunnel between Switch A and Switch B to secure the communication between the switches.

- Configure the two switches to use the default IKE proposal for the IKE negotiation.
- Configure the two switches to use the preshared key authentication method for the IKE negotiation.

Figure 14 Network diagram

Procedure

1. Make sure Switch A and Switch B can reach each other.
2. Configure Switch A:

   # Assign IP addresses to interfaces.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 1
   ```

```
[SwitchA-vlan1] quit
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] port access vlan 1
[SwitchA-GigabitEthernet1/0/1] quit
[SwitchA] interface vlan-interface 1
[SwitchA-vlan-interface1] ip address 1.1.1.1 255.255.0.0
[SwitchA-vlan-interface1] quit
```

Configure a static route to Switch B. In this example, the next hop in the route is 1.1.1.2.

```
[SwitchA] ip route-static 2.2.0.0 255.255.0.0 1.1.1.2
```

Configure IPv4 advanced ACL 3101 to identify the traffic from Switch A to Switch B.

```
[SwitchA] acl advanced 3101
[SwitchA-acl-ipv4-adv-3101] rule 0 permit ip source 1.1.1.1 0 destination 2.2.2.2 0
[SwitchA-acl-ipv4-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

Set the packet encapsulation mode to **tunnel**.

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Use the ESP protocol for the IPsec transform set.

```
[SwitchA-ipsec-transform-set-tran1] protocol esp
```

Specify the encryption and authentication algorithms.

```
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchA] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.2.2.

```
[SwitchA-ike-keychain-keychain1] pre-shared-key address 2.2.2.2 255.255.0.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchA-ike-keychain-keychain1] quit
```

Create an IKE profile named **profile1**.

```
[SwitchA] ike profile profile1
```

Specify IKE keychain **keychain1**.

```
[SwitchA-ike-profile-profile1] keychain keychain1
```

Configure a peer ID with the identity type as IP address and the value as **2.2.2.2/16**.

```
[SwitchA-ike-profile-profile1] match remote identity address 2.2.2.2 255.255.0.0
[SwitchA-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 isakmp
```

Specify the remote IP address 2.2.2.2 for the IPsec tunnel.

```
[SwitchA-ipsec-policy-isakmp-map1-10] remote-address 2.2.2.2
```

Specify ACL 3101 to identify the traffic to be protected.

```
[SwitchA-ipsec-policy-isakmp-map1-10] security acl 3101
```

Specify IPsec transform set **tran1** for the IPsec policy.

```
[SwitchA-ipsec-policy-isakmp-map1-10] transform-set tran1
```

Specify IKE profile **profile1** for the IPsec policy.

```
[SwitchA-ipsec-policy-isakmp-map1-10] ike-profile profile1
[SwitchA-ipsec-policy-isakmp-map1-10] quit
```

Apply IPsec policy **map1** to VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipsec apply policy map1
```

3. Configure Switch B:

Assign IP addresses to interfaces.

```
<SwitchB> system-view
[SwitchB] vlan 1
[SwitchB-vlan1] quit
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port access vlan 1
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface Vlan-interface1
[SwitchB-Vlan-interface1] ip address 2.2.2.2 255.255.0.0
[SwitchB-Vlan-interface1] quit
```

Configure a static route to Switch A. In this example, the next hop in the route is 2.2.2.3.

```
[SwitchB] ip route-static 1.1.0.0 255.255.0.0 2.2.2.3
```

Configure IPv4 advanced ACL 3101 to identify the traffic from Switch B to Switch A.

```
[SwitchB] acl number 3101
[SwitchB-acl-adv-3101] rule 0 permit ip source 2.2.2.2 0 destination 1.1.1.1 0
[SwitchB-acl-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Set the packet encapsulation mode to **tunnel**.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Use the ESP protocol for the IPsec transform set.

```
[SwitchB-ipsec-transform-set-tran1] protocol esp
```

Specify the encryption and authentication algorithms.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchB]ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 1.1.1.1.

```
[SwitchB-ike-keychain-keychain1] pre-shared-key address 1.1.1.1 255.255.0.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchB-ike-keychain-keychain1] quit
```

Create an IKE profile named **profile1**.

```
[SwitchB] ike profile profile1
```

Specify IKE keychain **keychain1**

```
[SwitchB-ike-profile-profile1] keychain keychain1
```

Configure a peer ID with the identity type as IP address and the value as **1.1.1.1/16**.

```
[SwitchB-ike-profile-profile1] match remote identity address 1.1.1.1 255.255.0.0
[SwitchB-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **use1** and set the sequence number to 10.

```
[SwitchB] ipsec policy use1 10 isakmp
```

Specify the remote IP address 1.1.1.1 for the IPsec tunnel.

```
[SwitchB-ipsec-policy-isakmp-use1-10] remote-address 1.1.1.1
```

Specify ACL 3101 to identify the traffic to be protected.

```
[SwitchB-ipsec-policy-isakmp-use1-10] security acl 3101
```

Specify IPsec transform set **tran1** for the IPsec policy.

```
[SwitchB-ipsec-policy-isakmp-use1-10] transform-set tran1
```

Specify IKE profile **profile1** for the IPsec policy.

```
[SwitchB-ipsec-policy-isakmp-use1-10] ike-profile profile1
[SwitchB-ipsec-policy-isakmp-use1-10] quit
```

Apply IPsec policy **use1** to VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ipsec apply policy use1
```

Verifying the configuration

Initiate a connection between Switch A and Switch B to trigger IKE negotiation. After IPsec SAs are successfully negotiated by IKE, the traffic between the two switches is IPsec-protected.

Configuration files

Switch A

```
#

```

Example: Configuring an IKE-based IPsec tunnel for IPv4 packets

Network configuration

As shown in Figure 15, establish an IPsec tunnel between Switch A and Switch B to protect data flows between the switches. Configure the IPsec tunnel as follows:

- Specify the encapsulation mode as tunnel, the security protocol as ESP, the encryption algorithm as AES-CBC-192, and the authentication algorithm as HMAC-SHA1.
- Set up SAs through IKE negotiation.

Figure 15 Network diagram

Procedure

1. Configure Switch A:

Assign IP addresses to interfaces.

```
<SwitchA> system-view
[SwitchA] vlan 1
[SwitchA-vlan1] quit
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] port access vlan 1
[SwitchA-GigabitEthernet1/0/1] quit
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ip address 2.2.2.1 255.255.255.0
[SwitchA-Vlan-interface1] quit
```

Configure a static route to Switch B. In this example, the next hop in the route is 2.2.2.3.

```
[SwitchA] ip route-static 2.2.3.0 255.255.255.0 2.2.2.3
```

Configure an IPv4 advanced ACL to identify the data flows from Switch A to Switch B.

```
[SwitchA] acl advanced 3101
[SwitchA-acl-ipv4-adv-3101] rule 0 permit ip source 2.2.2.1 0 destination 2.2.3.1 0
[SwitchA-acl-ipv4-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchA-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchA] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.3.1.

```
[SwitchA-ike-keychain-keychain1] pre-shared-key address 2.2.3.1 255.255.255.0 key simple 12345zxcvb!@#$%ZXCVB
[SwitchA-ike-keychain-keychain1] quit
```

Create and configure an IKE profile named **profile1**.

```
[SwitchA] ike profile profile1
[SwitchA-ike-profile-profile1] keychain keychain1
[SwitchA-ike-profile-profile1] match remote identity address 2.2.3.1 255.255.255.0
[SwitchA-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 isakmp
```

Specify ACL 3101.

```
[SwitchA-ipsec-policy-isakmp-map1-10] security acl 3101
```

Specify IPsec transform set **tran1**.

```
[SwitchA-ipsec-policy-isakmp-map1-10] transform-set tran1
```

Specify the local and remote IP addresses of the IPsec tunnel as 2.2.2.1 and 2.2.3.1.

```
[SwitchA-ipsec-policy-isakmp-map1-10] local-address 2.2.2.1
[SwitchA-ipsec-policy-isakmp-map1-10] remote-address 2.2.3.1
```

Specify IKE profile **profile1**.

```
[SwitchA-ipsec-policy-isakmp-map1-10] ike-profile profile1
[SwitchA-ipsec-policy-isakmp-map1-10] quit
```

Apply IPsec policy **map1** to VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipsec apply policy map1
```

2. Configure Switch B:

Assign IP addresses to interfaces.

```
<SwitchB> system-view
[SwitchB] vlan 1
[SwitchB-vlan1] quit
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port access vlan 1
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ip address 2.2.3.1 255.255.255.0
[SwitchB-Vlan-interface1] quit
```

Configure a static route to Switch A. In this example, the next hop in the route is 3.3.3.2.

```
[SwitchB] ip route-static 2.2.2.0 255.255.255.0 3.3.3.2
```

Configure an IPv4 advanced ACL to identify the data flows from Switch B to Switch A.

```
[SwitchB] acl advanced 3101
[SwitchB-acl-ipv4-adv-3101] rule 0 permit ip source 2.2.3.1 0 destination 2.2.2.1 0
[SwitchB-acl-ipv4-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchB-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchB] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.2.1.

```
[SwitchB-ike-keychain-keychain1] pre-shared-key address 2.2.2.1 255.255.255.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchB-ike-keychain-keychain1] quit
```

Create and configure an IKE profile named **profile1**.

```
[SwitchB] ike profile profile1
[SwitchB-ike-profile-profile1] keychain keychain1
[SwitchB-ike-profile-profile1] match remote identity address 2.2.2.1 255.255.255.0
[SwitchB-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **use1** and set the sequence number to 10.

```
[SwitchB] ipsec policy use1 10 isakmp
```

Specify ACL 3101.

```
[SwitchB-ipsec-policy-isakmp-use1-10] security acl 3101
```

Specify IPsec transform set **tran1**.

```
[SwitchB-ipsec-policy-isakmp-use1-10] transform-set tran1
```

Specify the local and remote IP addresses of the IPsec tunnel as 2.2.3.1 and 2.2.2.1.

```
[SwitchB-ipsec-policy-isakmp-use1-10] local-address 2.2.3.1
[SwitchB-ipsec-policy-isakmp-use1-10] remote-address 2.2.2.1
```

Specify IKE profile **profile1**.

```
[SwitchB-ipsec-policy-isakmp-use1-10] ike-profile profile1
[SwitchB-ipsec-policy-isakmp-use1-10] quit
```

Apply IPsec policy **use1** to VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ipsec apply policy use1
```

Verifying the configuration

Initiate a connection between Switch A and Switch B to trigger IKE negotiation. After IPsec SAs are successfully negotiated by IKE, the traffic between the two switches is IPsec-protected.

Configuration files

Switch A

```
#
sysname SwitchA
#
vlan 1
#
interface gigabitethernet 1/0/1
port access vlan 1
#
```

```
interface vlan-interface 1
ip address 2.2.2.1 255.255.255.0
#
ip route-static 2.2.3.0 255.255.255.0 2.2.2.3

ipsec apply policy use1
#
```

Troubleshooting IKE

IKE negotiation failed because no matching IKE proposals were found

Symptom

1. The IKE SA is in Unknown state.

```
<Sysname> display ike sa
    Connection-ID   Remote                Flag         DOI
-----------------------------------------------------------------
    1               192.168.222.5         Unknown      IPsec
Flags:
RD--READY RL--REPLACED FD-FADING RK-REKEY
```

2. When IKE event debugging and packet debugging are enabled, the following messages appear:

   IKE event debugging message:

   ```
   The attributes are unacceptable.
   ```

   IKE packet debugging message:

   ```
   Construct notification packet: NO_PROPOSAL_CHOSEN.
   ```

Analysis

Certain IKE proposal settings are incorrect.

Solution

1. Examine the IKE proposal configuration to see whether the two ends have matching IKE proposals.

2. Modify the IKE proposal configuration to make sure the two ends have matching IKE proposals.

IKE negotiation failed because no IKE proposals or IKE keychains are specified correctly

Symptom

1. The IKE SA is in Unknown state.

```
<Sysname> display ike sa
    Connection-ID   Remote                Flag         DOI
-----------------------------------------------------------------
    1               192.168.222.5         Unknown      IPsec
Flags:
RD--READY RL--REPLACED FD-FADING RK-REKEY
```

2. The following IKE event debugging or packet debugging message appeared:

   IKE event debugging message:

```
Notification PAYLOAD_MALFORMED is received.
```

   IKE packet debugging message:

```
Construct notification packet: PAYLOAD_MALFORMED.
```

Analysis

- If the following debugging information appeared, the matched IKE profile is not using the matched IKE proposal:

```
Failed to find proposal 1 in profile profile1.
```

- If the following debugging information appeared, the matched IKE profile is not using the matched IKE keychain:

```
Failed to find keychain keychain1 in profile profile1.
```

Solution

- Verify that the matched IKE proposal (IKE proposal 1 in this debugging message example) is specified for the IKE profile (IKE profile 1 in the example).
- Verify that the matched IKE keychain (IKE keychain 1 in this debugging message example) is specified for the IKE profile (IKE profile 1 in the example).

IPsec SA negotiation failed because no matching IPsec transform sets were found

Symptom

1. The **`display ike sa`** command shows that the IKE SA negotiation succeeded and the IKE SA is in RD state, but the **`display ipsec sa`** command shows that the expected IPsec SA has not been negotiated yet.
2. The following IKE debugging message appeared:

```
The attributes are unacceptable.
```

   Or:

```
Construct notification packet: NO_PROPOSAL_CHOSEN.
```

Analysis

Certain IPsec policy settings are incorrect.

Solution

1. Examine the IPsec configuration to see whether the two ends have matching IPsec transform sets.
2. Modify the IPsec configuration to make sure the two ends have matching IPsec transform sets.

IPsec SA negotiation failed due to invalid identity information

Symptom

1. The **display ike sa** command shows that the IKE SA negotiation succeeded and the IKE SA is in RD state, but the **display ipsec sa** command shows that the expected IPsec SA has not been negotiated yet.
2. The following IKE debugging message appeared:

   ```
   Notification INVALID_ID_INFORMATION is received.
   ```

   Or:

   ```
   Failed to get IPsec policy when renegotiating IPsec SA. Delete IPsec SA.
   Construct notification packet: INVALID_ID_INFORMATION.
   ```

Analysis

Certain IPsec policy settings of the responder are incorrect. Verify the settings as follows:

1. Use the **display ike sa verbose** command to verify that matching IKE profiles were found in IKE negotiation phase 1. If no matching IKE profiles were found and the IPsec policy is using an IKE profile, the IPsec SA negotiation fails.

   # Identify whether matching IKE profiles were found in IKE negotiation phase 1. The following output shows that no matching IKE profile was found:

   ```
   <Sysname> display ike sa verbose
      ---------------------------------------------
      Connection ID: 3
      Outside VPN:
      Inside VPN:
      Profile:
      Transmitting entity: Responder
      ---------------------------------------------
      Local IP: 192.168.222.5
      Local ID type: IPV4_ADDR
      Local ID: 192.168.222.5

      Remote IP: 192.168.222.71
      Remote ID type: IPV4_ADDR
      Remote ID: 192.168.222.71

      Authentication-method: PRE-SHARED-KEY
      Authentication-algorithm: MD5
      Encryption-algorithm: 3DES-CBC

      Life duration(sec): 86400
      Remaining key duration(sec): 85847
      Exchange-mode: Main
      Diffie-Hellman group: Group 1
   ```

```
   NAT traversal: Not detected
```

Identify whether the IPsec policy is using an IKE profile. The following output shows that the IPsec policy is using an IKE profile.

```
[Sysname] display ipsec policy
-----------------------------------------
IPsec Policy: policy1
Interface: GigabitEthernet1/0/1
-----------------------------------------

  ----------------------------
  Sequence number: 1
  Mode: ISAKMP
  ----------------------------
  Description:
  Security data flow: 3000
  Selector mode: aggregation
  Local address: 192.168.222.5
  Remote address: 192.168.222.71
  Transform set:  transform1
  IKE profile: profile1
  SA duration(time based):
  SA duration(traffic based):
  SA idle time:
```

2. Verify that the ACL specified for the IPsec policy is correctly configured. If the flow range defined by the responder's ACL is smaller than that defined by the initiator's ACL, IPsec proposal matching will fail.

For example, if the initiator's ACL defines a flow from one network segment to another but the responder's ACL defines a flow from one host to another host, IPsec proposal matching will fail.

On the initiator:

```
[Sysname] display acl 3000
Advanced IPv4 ACL 3000, 1 rule,
ACL's step is 5
 rule 0 permit ip source 192.168.222.0 0.0.0.255 destination 192.168.222.0 0.0.0.255
```

On the responder:

```
[Sysname] display acl 3000
Advanced IPv4 ACL 3000, 1 rule,
ACL's step is 5
 rule 0 permit ip source 192.168.222.71 0 destination 192.168.222.5 0
```

3. Verify that the IPsec policy has a remote address and an IPsec transform set configured and that the IPsec transform set has all necessary settings configured.

If, for example, the IPsec policy has no remote address configured, the IPsec SA negotiation will fail:

```
[Sysname] display ipsec policy
-----------------------------------------
IPsec Policy: policy1
Interface: GigabitEthernet1/0/1
-----------------------------------------

  ----------------------------
```

```
Sequence number: 1
Mode: ISAKMP
-----------------------------
Security data flow: 3000
Selector mode: aggregation
Local address: 192.168.222.5
Remote address:
Transform set:  transform1
IKE profile: profile1
SA duration(time based):
SA duration(traffic based):
SA idle time:
```

Solution

1. If the IPsec policy specifies an IKE profile but no matching IKE profiles was found in IKE negotiation, perform one of the following tasks on the responder:
   - Remove the specified IKE profile from the IPsec policy.
   - Modify the specified IKE profile to match the IKE profile of the initiator.
2. If the flow range defined by the responder's ACL is smaller than that defined by the initiator's ACL, modify the responder's ACL so the ACL defines a flow range equal to or greater than that of the initiator's ACL.

   For example:

   ```
   [Sysname] display acl 3000
   Advanced IPv4 ACL 3000, 2 rules,
   ACL's step is 5
    rule 0 permit ip source 192.168.222.0 0.0.0.255 destination 192.168.222.0 0.0.0.255
   ```
3. Configure the missing settings (for example, the remote address).

Configuring IKEv2

About IKEv2

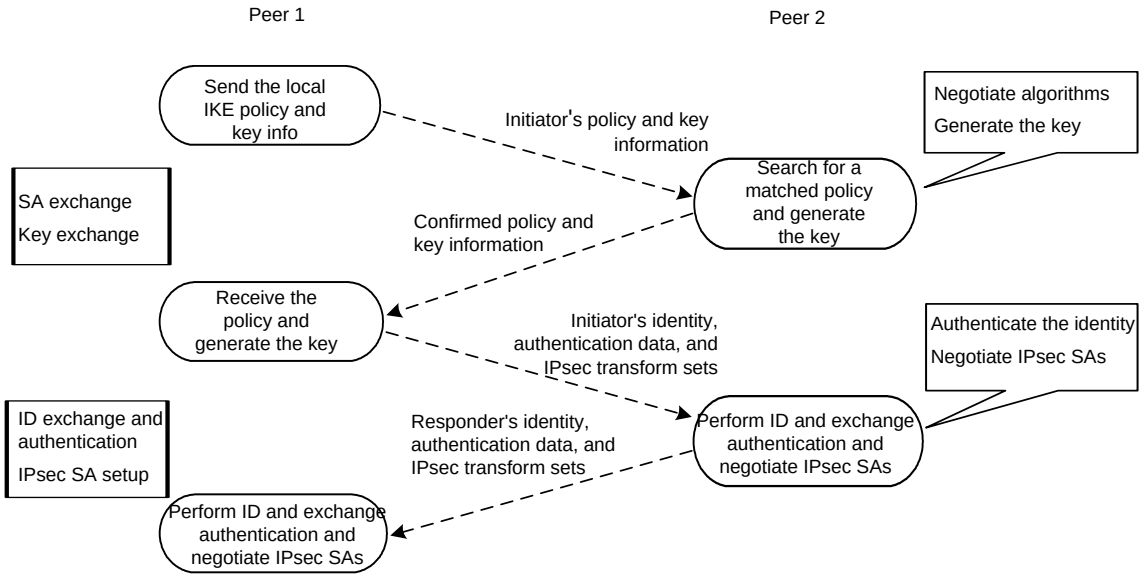
Internet Key Exchange version 2 (IKEv2) is an enhanced version of IKEv1. The same as IKEv1, IKEv2 has a set of self-protection mechanisms and can be used on insecure networks for reliable identity authentication, key distribution, and IPsec SA negotiation. IKEv2 provides stronger protection against attacks and higher key exchange ability and needs fewer message exchanges than IKEv1.

IKEv2 negotiation process

Compared with IKEv1, IKEv2 simplifies the negotiation process and is much more efficient.

IKEv2 defines three types of exchanges: initial exchanges, CREATE_CHILD_SA exchange, and INFORMATIONAL exchange.

As shown in Figure 16, IKEv2 uses two exchanges during the initial exchange process: IKE_SA_INIT and IKE_AUTH, each with two messages.



- **IKE_SA_INIT exchange**—Negotiates IKE SA parameters and exchanges keys.
- **IKE_AUTH exchange**—Authenticates the identity of the peer and establishes IPsec SAs.

After the four-message initial exchanges, IKEv2 sets up one IKE SA and one pair of IPsec SAs. For IKEv1 to set up one IKE SA and one pair of IPsec SAs, it must go through two phases that use a minimum of six messages.

To set up one more pair of IPsec SAs within the IKE SA, IKEv2 goes on to perform an additional two-message exchange—the CREATE_CHILD_SA exchange. One CREATE_CHILD_SA exchange creates one pair of IPsec SAs. IKEv2 also uses the CREATE_CHILD_SA exchange to rekey IKE SAs and Child SAs.

IKEv2 uses the INFORMATIONAL exchange to convey control messages about errors and notifications.

Figure 16 IKEv2 Initial exchange process

New features in IKEv2

DH guessing

In the IKE_SA_INIT exchange, the initiator guesses the DH group that the responder is most likely to use and sends it in an IKE_SA_INIT request message. If the initiator's guess is correct, the responder responds with an IKE_SA_INIT response message and the IKE_SA_INIT exchange is finished. If the guess is wrong, the responder responds with an INVALID_KE_PAYLOAD message that contains the DH group that it wants to use. The initiator then uses the DH group selected by the responder to reinitiate the IKE_SA_INIT exchange. The DH guessing mechanism allows for more flexible DH group configuration and enables the initiator to adapt to different responders.

Cookie challenging

Messages for the IKE_SA_INIT exchange are in plain text. An IKEv1 responder cannot confirm the validity of the initiators and must maintain half-open IKE SAs, which makes the responder susceptible to DoS attacks. An attacker can send a large number of IKE_SA_INIT requests with forged source IP addresses to the responder, exhausting the responder's system resources.

IKEv2 introduces the cookie challenging mechanism to prevent such DoS attacks. When an IKEv2 responder maintains a threshold number of half-open IKE SAs, it starts the cookie challenging mechanism. The responder generates a cookie and includes it in the response sent to the initiator. If the initiator initiates a new IKE_SA_INIT request that carries the correct cookie, the responder considers the initiator valid and proceeds with the negotiation. If the carried cookie is incorrect, the responder terminates the negotiation.

The cookie challenging mechanism automatically stops working when the number of half-open IKE SAs drops below the threshold.

IKEv2 SA rekeying

For security purposes, both IKE SAs and IPsec SAs have a lifetime and must be rekeyed when the lifetime expires. An IKEv1 SA lifetime is negotiated. An IKEv2 SA lifetime, in contrast, is configured. If two peers are configured with different lifetimes, the peer with the shorter lifetime always initiates the SA rekeying. This mechanism reduces the possibility that two peers will simultaneously initiate a rekeying. Simultaneous rekeying results in redundant SAs and SA status inconsistency on the two peers.

IKEv2 message retransmission

Unlike IKEv1 messages, IKEv2 messages appear in request/response pairs. IKEv2 uses the Message ID field in the message header to identify the request/response pair. If an initiator sends a request but receives no response with the same Message ID value within a specific period of time, the initiator retransmits the request.

It is always the IKEv2 initiator that initiates the retransmission, and the retransmitted message must use the same Message ID value.

Protocols and standards

- RFC 2408, *Internet Security Association and Key Management Protocol (ISAKMP)*
- RFC 4306, *Internet Key Exchange (IKEv2) Protocol*
- RFC 4718, *IKEv2 Clarifications and Implementation Guidelines*
- RFC 2412, *The OAKLEY Key Determination Protocol*
- RFC 5996, *Internet Key Exchange Protocol Version 2 (IKEv2)*

IKEv2 tasks at a glance

To configure IKEv2, perform the following tasks:

1. Configuring an IKEv2 profile
   a. Creating an IKEv2 profileSpecifying the local and remote identity authentication methodsConfiguring the IKEv2 keychain or PKI domain
   b. Configuring the local ID for the IKEv2 profile
   c. Configuring peer IDs for the IKEv2 profile
   d. Specifying a VPN instance for the IKEv2 profile
   e. Configuring optional features for the IKEv2 profile
2. Configuring an IKEv2 policy
3. Configuring an IKEv2 proposal

   If you specify an IKEv2 proposal in an IKEv2 policy, you must configure the IKEv2 proposal.
4. Configuring an IKEv2 keychain

   This task is required when either end or both ends use the preshared key authentication method.
5. (Optional.) Enabling the cookie challenging feature

   The cookie challenging feature takes effect only on IKEv2 responders.
6. (Optional.) Configuring the IKEv2 DPD feature
7. (Optional.) Configuring the IKEv2 NAT keepalive feature
8. (Optional.) Configuring IKEv2 address pools

Prerequisites for IKEv2 configuration

Determine the following parameters prior to IKEv2 configuration:

- The strength of the algorithms for IKEv2 negotiation, including the encryption algorithms, integrity protection algorithms, PRF algorithms, and DH groups. Different algorithms provide different levels of protection. A stronger algorithm means better resistance to decryption of protected data but requires more resources. Typically, the longer the key, the stronger the algorithm.
- The local and remote identity authentication methods.
  - To use the preshared key authentication method, you must determine the preshared key.
  - To use the RSA digital signature authentication method, you must determine the PKI domain for the local end to use. For information about PKI, see "Configuring PKI."

Configuring an IKEv2 profile

Creating an IKEv2 profile

About this task

An IKEv2 profile is intended to provide a set of parameters for IKEv2 negotiation.

Procedure

1. Enter system view.

   `system-view`
2. Create an IKEv2 profile and enter its view.

   `ikev2 profile` *`profile-name`*

Specifying the local and remote identity authentication methods

Restrictions and guidelines

The local and remote identity authentication methods must both be specified and they can be different. You can specify only one local identity authentication method and multiple remote identity authentication methods.

Procedure

1. Enter system view.

   system-view

2. Enter IKEv2 profile view.

   ikev2 profile *profile-name*

3. Specify the local and remote identity authentication methods.

   In non-FIPS mode:

   authentication-method { **local** | **remote** } { **dsa-signature** | **ecdsa-signature** | **pre-share** | **rsa-signature** }

   In FIPS mode:

   authentication-method { **local** | **remote** } { **ecdsa-signature** | **pre-share** | **rsa-signature** }

   By default, no local or remote identity authentication method is configured.

Configuring the IKEv2 keychain or PKI domain

Restrictions and guidelines

Configure the IKEv2 keychain or PKI domain for the IKEv2 profile to use. To use digital signature authentication, configure a PKI domain. To use preshared key authentication, configure an IKEv2 keychain.

Procedure

1. Enter system view.

   system-view

2. Enter IKEv2 profile view.

   ikev2 profile *profile-name*

3. Specify the keychain for preshared key authentication or the PKI domain used to request a certificate for digital signature authentication.

   - Specify the keychain.

     keychain *keychain-name*

   - Specify the PKI domain.

     certificate domain *domain-name* [**sign** | **verify**]

   By default, no IKEv2 keychain or PKI domain is specified for an IKEv2 profile.

Configuring the local ID for the IKEv2 profile

Restrictions and guidelines

For digital signature authentication, the device can use an ID of any type. If the local ID is an IP address that is different from the IP address in the local certificate, the device uses the FQDN as the local ID. The FQDN is the device name configured by using the **sysname** command.

For preshared key authentication, the device can use an ID of any type other than the DN.

Procedure

1. Enter system view.

   system-view

2. Enter IKEv2 profile view.

   ikev2 profile *profile-name*

3. Configure the local ID.

   identity local { **address** { *ipv4-address* | **ipv6** *ipv6-address* } | **dn** | **email** *email-string* | **fqdn** *fqdn-name* | **key-id** *key-id-string* }

   By default, no local ID is configured, and the device uses the IP address of the interface where the IPsec policy applies as the local ID.

Configuring peer IDs for the IKEv2 profile

About this task

Perform this task to configure the peer ID for IKEv2 profile matching. When the device needs to select an IKEv2 profile for IKEv2 negotiation with a peer, it compares the received peer ID with the peer IDs of its local IKE profiles. If a match is found, it uses the IKEv2 profile with the matching peer ID for negotiation. IKEv2 profiles will be compared in descending order of their priorities.

Procedure

1. Enter system view.

   system-view

2. Enter IKEv2 profile view.

   ikev2 profile *profile-name*

3. Configure a peer ID.

   match remote { **certificate** *policy-name* | **identity** { **address** { { *ipv4-address* [*mask* | *mask-length*] | **range** *low-ipv4-address high-ipv4-address* } | **ipv6** { *ipv6-address* [*prefix-length*] | **range** *low-ipv6-address high-ipv6-address* } } | **fqdn** *fqdn-name* | **email** *email-string* | **key-id** *key-id-string* } }

   You must configure a minimum of one peer ID on each of the two peers.

Specifying a VPN instance for the IKEv2 profile

About this task

After you specify a VPN instance for an IKEv2 profile, the IKEv2 profile can be used for IKEv2 negotiation only on the interfaces that belong to the VPN instance.

Procedure

1. Enter system view.

system-view

2. Enter IKEv2 profile view.
   ikev2 profile *profile-name*
3. Specify a VPN instance for the IKEv2 profile.
   match vrf { **name** *vrf-name* | **any** }
   By default, an IKEv2 profile belongs to the public network.

Configuring optional features for the IKEv2 profile

1. Enter system view.
   system-view
2. Enter IKEv2 profile view.
   ikev2 profile *profile-name*
3. Configure optional features as needed.
   - Configure IKEv2 DPD.
     dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }
     By default, IKEv2 DPD is not configured for an IKEv2 profile and an IKEv2 profile uses the DPD settings configured in system view. If IKEv2 DPD is not configured in system view either, the device does not perform dead IKEv2 peer detection.
   - Specify the local interface or IP address to which the IKEv2 profile can be applied.
     match local address { *interface-type interface-number* | *ipv4-address* | **ipv6** *ipv6-address* }
     By default, an IKEv2 profile can be applied to any local interface or local IP address.
     Use this command to specify which address or interface can use the IKEv2 profile for IKEv2 negotiation. Specify the local address configured in IPsec policy or IPsec policy template view (using the **local-address** command) for this command. If no local address is configured, specify the IP address of the interface that uses the IPsec policy.
   - Specify a priority for the IKEv2 profile.
     priority *priority*
     By default, the priority of an IKEv2 profile is 100.
     When the device needs to select an IKEv2 profile for IKEv2 negotiation with a peer, it compares the received peer ID with the peer ID of its local IKEv2 profiles in descending order of their priorities
   - Set the IKEv2 SA lifetime for the IKEv2 profile.
     sa duration *seconds*
     By default, the IKEv2 SA lifetime is 86400 seconds.
     The local and remote ends can use different IKEv2 SA lifetimes and they do not negotiate the lifetime. The end with a smaller SA lifetime will initiate an SA negotiation when the lifetime expires.
   - Set the IKEv2 NAT keepalive interval.
     nat-keepalive *seconds*
     By default, the global IKEv2 NAT keepalive setting is used.
     Configure this command when the device is behind a NAT gateway. The device sends NAT keepalive packets regularly to its peer to prevent the NAT session from being aged because of no matching traffic.
   - Enable the configuration exchange feature.
     config-exchange { **request** | **set** { **accept** | **send** } }

By default, all configuration exchange options are disabled.

This feature applies to scenarios where the headquarters and branches communicate through virtual tunnels. It enables exchanges of IP address request and set messages between the IPsec gateway at a branch and the IPsec gateway at the headquarters.

Table 2 Parameter descriptions

Parameter	Description
request	Enables the IPsec gateway at a branch to submit IP address request messages to the IPsec gateway at the headquarters.
set accept	Enables the IPsec gateway at a branch to accept the IP addresses pushed by the IPsec gateway at the headquarters.
set send	Enables the IPsec gateway at the headquarters to push IP addresses to IPsec gateways at branches.

- Enable AAA authorization.

  aaa authorization domain *domain-name* **username** *user-name*

  By default, AAA authorization is disabled.

  The AAA authorization feature enables IKEv2 to request authorization attributes, such as the IKEv2 address pool, from AAA. IKEv2 uses the address pool to assign IP addresses to remote users. For more information about AAA authorization, see "Configuring AAA."

Configuring an IKEv2 policy

About this task

During the IKE_SA_INIT exchange, each end tries to find a matching IKEv2 policy, using the IP address of the local security gateway as the matching criterion.

- If IKEv2 policies are configured, IKEv2 searches for an IKEv2 policy that uses the IP address of the local security gateway. If no IKEv2 policy uses the IP address or the policy is using an incomplete proposal, the IKE_SA_INIT exchange fails.
- If no IKEv2 policy is configured, IKEv2 uses the system default IKEv2 policy **default**.

The device matches IKEv2 policies in the descending order of their priorities. To determine the priority of an IKEv2 policy:

1. First, the device examines the existence of the **match local address** command. An IKEv2 policy with the **match local address** command configured has a higher priority.
2. If a tie exists, the device compares the priority numbers. An IKEv2 policy with a smaller priority number has a higher priority.
3. If a tie still exists, the device prefers an IKEv2 policy configured earlier.

Procedure

1. Enter system view.

   system-view
2. Create an IKEv2 policy and enter its view.

   ikev2 policy *policy-name*

   By default, an IKEv2 policy named **default** exists.
3. Specify the local interface or address used for IKEv2 policy matching.

   match local address { *interface-type interface-number* | *ipv4-address* | **ipv6** *ipv6-address* }

By default, no local interface or address is used for IKEv2 policy matching, and the policy matches any local interface or address.

4. Specify a VPN instance for IKEv2 policy matching.

   match vrf { **name** *vrf-name* | **any** }

   By default, no VPN instance is specified for IKEv2 policy matching. The IKEv2 policy matches all local addresses in the public network.

5. Specify an IKEv2 proposal for the IKEv2 policy.

   proposal *proposal-name*

   By default, no IKEv2 proposal is specified for an IKEv2 policy.

6. Specify a priority for the IKEv2 policy.

   priority *priority*

   By default, the priority of an IKEv2 policy is 100.

Configuring an IKEv2 proposal

About this task

An IKEv2 proposal contains security parameters used in IKE_SA_INIT exchanges, including the encryption algorithms, integrity protection algorithms, PRF algorithms, and DH groups. An algorithm specified earlier has a higher priority.

Restrictions and guidelines

A complete IKEv2 proposal must have at least one set of security parameters, including one encryption algorithm, one integrity protection algorithm, one PRF algorithm, and one DH group.

You can specify multiple IKEv2 proposals for an IKEv2 policy. A proposal specified earlier has a higher priority.

Procedure

1. Enter system view.

   system-view

2. Create an IKEv2 proposal and enter its view.

   ikev2 proposal *proposal-name*

   By default, an IKEv2 proposal named **default** exists.

   In non-FIPS mode, the default proposal uses the following settings:

   - Encryption algorithms AES-CBC-128 and 3DES.
   - Integrity protection algorithms HMAC-SHA1 and HMAC-MD5.
   - PRF algorithms HMAC-SHA1 and HMAC-MD5.
   - DH groups 2 and 5.

   In FIPS mode, the default proposal uses the following settings:

   - Encryption algorithms AES-CBC-128 and AES-CTR-128.
   - Integrity protection algorithms HMAC-SHA1 and HMAC-SHA256.
   - PRF algorithms HMAC-SHA1 and HMAC-SHA256.
   - DH groups 14 and 19.

3. Specify the encryption algorithms.

   In non-FIPS mode:

   encryption { **3des-cbc** | **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **aes-ctr-128** | **aes-ctr-192** | **aes-ctr-256** | **camellia-cbc-128** |

camellia-cbc-192 | **camellia-cbc-256** | **des-cbc** | **aes-gcm-128** | **aes-gcm-192** | **aes-gcm-256** } *

In FIPS mode:

encryption { **aes-gcm-128** | **aes-gcm-192** | **aes-gcm-256** } *

By default, an IKEv2 proposal does not have any encryption algorithms.

4. Specify the integrity protection algorithms.

   In non-FIPS mode:

   integrity { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** } *

   By default, an IKEv2 proposal does not have any integrity protection algorithms.

5. Specify the DH groups.

   In non-FIPS mode:

   dh { **group1** | **group14** | **group19** | **group2** | **group20** | **group24** | **group5** } *

   In FIPS mode:

   dh { **group19** | **group20** | **group24** } *

   By default, an IKEv2 proposal does not have any DH groups.

6. Specify the PRF algorithms.

   In non-FIPS mode:

   prf { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** } *

   In FIPS mode:

   prf { **sha256** | **sha384** | **sha512** } *

   By default, an IKEv2 proposal uses the integrity protection algorithms as the PRF algorithms.

Configuring an IKEv2 keychain

About this task

An IKEv2 keychain specifies the preshared keys used for IKEv2 negotiation.

An IKEv2 keychain can have multiple IKEv2 peers. Each peer has a symmetric preshared key or an asymmetric preshared key pair, and information for identifying the peer (such as the peer's host name, IP address or address range, or ID).

An IKEv2 negotiation initiator uses the peer host name or IP address/address range as the matching criterion to search for a peer. A responder uses the peer host IP address/address range or ID as the matching criterion to search for a peer.

Procedure

1. Enter system view.

   system-view

2. Create an IKEv2 keychain and enter its view.

   ikev2 keychain *keychain-name*

3. Create an IKEv2 peer and enter its view.

   peer *name*

4. Configure a host name for the peer:

   hostname *name*

   By default, no host name is configured for an IKEv2 peer.

5. Configure a host IP address or address range for the peer:

address { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] }

By default, no host IP address or address range is configured for an IKEv2 peer.

You must configure different host IP addresses/address ranges for different peers.

6. Configure an ID for the peer:

   identity { **address** { *ipv4-address* | **ipv6** { *ipv6-address* } } | **fqdn** *fqdn-name* | **email** *email-string* | **key-id** *key-id-string* }

   By default, no identity information is configured for an IKEv2 peer.

7. Configure a preshared key for the peer.

   pre-shared-key [**local** | **remote**] { **ciphertext** | **plaintext** } *string*

   By default, an IKEv2 peer does not have a preshared key.

Configure global IKEv2 parameters

Enabling the cookie challenging feature

About this task

Enable cookie challenging on responders to protect them against DoS attacks that use a large number of source IP addresses to forge IKE_SA_INIT requests.

Procedure

1. Enter system view.

   system-view

2. Enable IKEv2 cookie challenging.

   ikev2 cookie-challenge *number*

   By default, IKEv2 cookie challenging is disabled.

Configuring the IKEv2 DPD feature

About this task

IKEv2 DPD detects dead IKEv2 peers in periodic or on-demand mode.

- **Periodic IKEv2 DPD**—Verifies the liveness of an IKEv2 peer by sending DPD messages at regular intervals.
- **On-demand IKEv2 DPD**—Verifies the liveness of an IKEv2 peer by sending DPD messages before sending data.
  - Before the device sends data, it identifies the time interval for which the last IPsec packet has been received from the peer. If the time interval exceeds the DPD interval, it sends a DPD message to the peer to detect its liveliness.
  - If the device has no data to send, it never sends DPD messages.

Restrictions and guidelines

If you configure IKEv2 DPD in both IKEv2 profile view and system view, the IKEv2 DPD settings in IKEv2 profile view apply. If you do not configure IKEv2 DPD in IKEv2 profile view, the IKEv2 DPD settings in system view apply.

Procedure

1. Enter system view.

   system-view

2. Configure global IKEv2 DPD.

   ikev2 dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

   By default, global DPD is disabled.

Configuring the IKEv2 NAT keepalive feature

About this task

Configure this feature on the IKEv2 gateway behind the NAT device. The gateway then sends NAT keepalive packets regularly to its peer to keep the NAT session alive, so that the peer can access the device.

The NAT keepalive interval must be shorter than the NAT session lifetime.

This feature takes effect after the device detects the NAT device.

Procedure

1. Enter system view.

   system-view

2. Set the IKEv2 NAT keepalive interval.

   ikev2 nat-keepalive *seconds*

   By default, the IKEv2 NAT keepalive interval is 10 seconds.

Configuring IKEv2 address pools

About this task

To perform centralized management on remote users, an IPsec gateway can use an address pool to assign private IP addresses to remote users.

You must use an IKEv2 address pool together with AAA authorization by specifying the IKEv2 address pool as an AAA authorization attribute. For more information about AAA authorization, see "Configuring AAA."

Procedure

1. Enter system view.

   system-view

2. Configure an IKEv2 IPv4 address pool.

   ikev2 address-group *group-name start-ipv4-address end-ipv4-address* [*mask* | *mask-length*]

3. Configure an IKEv2 IPv6 address pool.

   ikev2 ipv6-address-group *group-name* **prefix** *prefix/prefix-len* **assign-len** *assign-len*

Display and maintenance commands for IKEv2

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the IKEv2 policy configuration.	**display ikev2 policy** [*policy-name* | **default**]

Task	Command
Display the IKEv2 profile configuration.	**display ikev2 profile** [*profile-name*]
Display the IKEv2 proposal configuration.	**display ikev2 proposal** [*name* | **default**]
Display the IKEv2 SA information.	**display ikev2 sa** [**count** | [{ **local** | **remote** } { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] [**verbose** [**tunnel** *tunnel-id*]]]
Display IKEv2 statistics.	**display ikev2 statistics**
Delete IKEv2 SAs and the child SAs negotiated through the IKEv2 SAs.	**reset ikev2 sa** [[{ **local** | **remote** } { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] | **tunnel** *tunnel-id*] [**fast**]
Clear IKEv2 statistics.	**reset ikev2 statistics**

Troubleshooting IKEv2

IKEv2 negotiation failed because no matching IKEv2 proposals were found

Symptom

The IKEv2 SA is in IN-NEGO status.

```
<Sysname> display ikev2 sa
Tunnel ID   Local                       Remote                      Status
  ------------------------------------------------------------------------------
  5           123.234.234.124/500         123.234.234.123/500         IN-NEGO
Status:
IN-NEGO: Negotiating, EST: Established, DEL:Deleting
```

Analysis

Certain IKEv2 proposal settings are incorrect.

Solution

1. Examine the IKEv2 proposal configuration to see whether the two ends have matching IKEv2 proposals.
2. Modify the IKEv2 proposal configuration to make sure the two ends have matching IKEv2 proposals.

IPsec SA negotiation failed because no matching IPsec transform sets were found

Symptom

The **display ikev2 sa** command shows that the IKEv2 SA negotiation succeeded and the IKEv2 SA is in EST status. The **display ipsec sa** command shows that the expected IPsec SAs have not been negotiated yet.

Analysis

Certain IPsec policy settings are incorrect.

Solution

1. Examine the IPsec configuration to see whether the two ends have matching IPsec transform sets.
2. Modify the IPsec configuration to make sure the two ends have matching IPsec transform sets.

IPsec tunnel establishment failed

Symptom

The ACLs and IKEv2 proposals are correctly configured on both ends. The two ends cannot establish an IPsec tunnel or cannot communicate through the established IPsec tunnel.

Analysis

The IKEv2 SA or IPsec SAs on either end are lost. The reason might be that the network is unstable and the device reboots.

Solution

1. Use the **display ikev2 sa** command to examine whether an IKEv2 SA exists on both ends. If the IKEv2 SA on one end is lost, delete the IKEv2 SA on the other end by using the **reset ikev2 sa** command and trigger new negotiation. If an IKEv2 SA exists on both ends, go to the next step.
2. Use the **display ipsec sa** command to examine whether IPsec SAs exist on both ends. If the IPsec SAs on one end are lost, delete the IPsec SAs on the other end by using the **reset ipsec sa** command and trigger new negotiation.

Configuring SSH

About SSH

Secure Shell (SSH) is a network security protocol. Using encryption and authentication, SSH can implement secure remote access and file transfer over an insecure network.

SSH uses the typical client-server model to establish a channel for secure data transfer based on TCP.

SSH includes two versions: SSH1.x and SSH2.0 (hereinafter referred to as SSH1 and SSH2), which are not compatible. SSH2 is better than SSH1 in performance and security.

SSH applications

The device supports the following SSH applications:

- **Secure Telnet**—Stelnet provides secure and reliable network terminal access services. Through Stelnet, a user can securely log in to a remote server. Stelnet can protect devices against attacks, such as IP spoofing and plain text password interception. The device can act as an Stelnet server or an Stelnet client.
- **Secure File Transfer Protocol**—Based on SSH2, SFTP uses SSH connections to provide secure file transfer. The device can act as an SFTP server, allowing a remote user to log in to the SFTP server for secure file management and transfer. The device can also act as an SFTP client, enabling a user to log in from the device to a remote device for secure file transfer.
- **Secure Copy**—Based on SSH2, SCP offers a secure method to copy files. The device can act as an SCP server, allowing a user to log in to the device for file upload and download. The device can also act as an SCP client, enabling a user to log in from the device to a remote device for secure file transfer.
- **NETCONF over SSH**—Based on SSH2, it enables users to securely log in to the device through SSH and perform NETCONF operations on the device through the NETCONF-over-SSH connections. The device can act only as a NETCONF-over-SSH server. For more information about NETCONF, see *Network Management and Monitoring Configuration Guide*.

The device supports different SSH versions depending on its role:

- When acting as an Stelnet server, the device supports both SSH2 and SSH1 in non-FIPS mode and only SSH2 in FIPS mode.
- When acting as an SSH client, the device supports only SSH2.
- When acting as an SFTP, SCP, or NETCONF-over-SSH server, the device supports only SSH2.

How SSH works

This section uses SSH2 as an example to describe the stages to establish an SSH session.

Table 1 Stages to establish an SSH session

Stages	Description
Connection establishment	The SSH server listens to connection requests on port 22. After a client initiates a connection request, the server and the client establish a TCP connection.
Version negotiation	The two parties determine a version to use.

Stages	Description
Algorithm negotiation	SSH supports multiple algorithms. Based on the local algorithms, the two parties negotiate the following algorithms: • Key exchange algorithm for generating session keys. • Encryption algorithm for encrypting data. • Public key algorithm for the digital signature and authentication. • HMAC algorithm for protecting data integrity.
Key exchange	The two parties use the DH exchange algorithm to dynamically generate the session keys and session ID. • The session keys are used for protecting data transfer. • The session ID is used for identifying the SSH connection. In this stage, the client also authenticates the server.
Authentication	The SSH server authenticates the client in response to the client's authentication request.
Session request	After passing the authentication, the client sends a session request to the server to request the establishment of a session for the Stelnet, NETCONF, SCP, or SFTP service.
Interaction	After the server grants the request, the client and the server start to communicate with each other in the session. In this stage, you can paste commands in text format and execute them at the CLI. The text pasted at one time must be no more than 2000 bytes. As a best practice to ensure the correct execution of commands, paste commands that are in the same view. To execute commands of more than 2000 bytes, save the commands in a configuration file, upload the file to the server through SFTP, and use it to restart the server.

SSH authentication methods

This section describes authentication methods that are supported by the device when it acts as an SSH server.

Password authentication

The SSH server authenticates a client through the AAA mechanism. The password authentication process is as follows:

1. The client sends the server an authentication request that includes the encrypted username and password.
2. The server performs the following operations:
   a. Decrypts the request to get the username and password in plain text.
   b. Verifies the username and password locally or through remote AAA authentication.
   c. Informs the client of the authentication result.

If the remote AAA server requires the user to enter a password for secondary authentication, it send the SSH server an authentication response carrying a prompt. The prompt is transparently transmitted to the client to notify the user to enter a specific password. When the user enters the correct password, the AAA sever examines the password validity. If the password is valid, the SSH server returns an authentication success message to the client.

SSH1 clients do not support secondary password authentication initiated by the AAA server.

For more information about AAA, see "Configuring AAA."

Keyboard-interactive authentication

In keyboard-interactive authentication, the remote authentication server and user exchanges information for authentication as follows:

1. The remote authentication server sends a prompt to the SSH server in an authentication response.
2. The prompt indicates the information required to be provided by the user.
3. The SSH server transparently transmits the prompt to the client terminal.
4. The user enters the required information as prompted.

This process repeats multiple times if the remote authentication server requires more interactive information. The remote authentication server returns an authentication success message after the user provides all required interactive information.

If the remote authentication server does not require interactive information, the keyboard-interactive authentication process is the same as the password authentication.

Publickey authentication

The server authenticates a client by verifying the digital signature of the client. The publickey authentication process is as follows:

1. The client sends the server a publickey authentication request that includes the username, public key, and public key algorithm name.

   If the digital certificate of the client is required in authentication, the client also encapsulates the digital certificate in the authentication request. The digital certificate carries the public key information of the client.
2. The server verifies the client's public key.
   - If the public key is invalid, the server informs the client of the authentication failure.
   - If the public key is valid, the server requests the digital signature of the client. After receiving the signature, the server uses the public key to verify the signature and informs the client of the authentication result.

When acting as an SSH server, the device supports using the public key algorithms DSA, ECDSA, and RSA to verify digital signatures.

When acting as an SSH client, the device supports using the public key algorithms DSA, ECDSA, and RSA to generate digital signatures.

For more information about public key configuration, see "Managing public keys."

Password-publickey authentication

The server requires SSH2 clients to pass both password authentication and publickey authentication. However, an SSH1 client only needs to pass either authentication.

Any authentication

The server requires clients to pass keyboard-interactive authentication, password authentication, or publickey authentication. Success with any one authentication method is sufficient to connect to the server.

SSH support for Suite B

Suite B contains a set of encryption and authentication algorithms that meet high security requirements. Table 2 lists all algorithms in Suite B.

The SSH server and client support using the X.509v3 certificate for identity authentication in compliance with the algorithm, negotiation, and authentication specifications defined in RFC 6239.

Table 2 Suite B algorithms

Security level	Key exchange algorithm	Encryption algorithm and HMAC algorithm	Public key algorithm
128-bit	ecdh-sha2-nistp256	AES128-GCM	x509v3-ecdsa-sha2-nistp256
192-bit	ecdh-sha2-nistp384	AES256-GCM	x509v3-ecdsa-sha2-nistp384
Both	ecdh-sha2-nistp256 ecdh-sha2-nistp384	AES128-GCM AES256-GCM	x509v3-ecdsa-sha2-nistp256 x509v3-ecdsa-sha2-nistp384

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see "Configuring FIPS."

Configuring the device as an SSH server

SSH server tasks at a glance

To configure an SSH server, perform the following tasks:

1. Generating local key pairs
2. (Optional.) Specifying the SSH service port
3. Enabling the SSH server
   - Enabling the Stelnet server
   - Enabling the SFTP server
   - Enabling the SCP server
   - Enabling NETCONF over SSH
4. Configuring the user lines for SSH login

   Required only for Stelnet and NETCONF-over-SSH servers.
5. Configuring a client's host public key

   Required for authentication method **publickey**, **password-publickey,** or **any**.
6. Configuring an SSH user
   - Required for authentication method **keyboard-interactive**, **publickey**, **password-publickey,** or **any**.
   - Optional for the **password** authentication method.
7. (Optional.) Configuring the SSH management parameters

   SSH management settings, such as authentication and connection control settings, help improve security of SSH connections.
8. (Optional.) Specifying a PKI domain for the SSH server
9. (Optional.) Disconnecting SSH sessions

Generating local key pairs

About this task

The DSA, ECDSA, or RSA key pairs on the SSH server are required for generating the session keys and session ID in the key exchange stage. They can also be used by a client to authenticate the server. When a client authenticates the server, it compares the public key received from the server with the server's public key that the client saved locally. If the keys are consistent, the client uses the locally saved server's public key to decrypt the digital signature received from the server. If the decryption succeeds, the server passes the authentication.

To support SSH clients that use different types of key pairs, generate DSA, ECDSA, and RSA key pairs on the SSH server.

- **RSA key pairs**—The SSH server generates a server key pair and a host key pair for RSA. The RSA server key pair is only used in SSH1 to encrypt the session key for secure transmission of the session key. It is not used in SSH2, because no session key transmission is required in SSH2.
- **DSA key pair**—The SSH server generates only one DSA host key pair. SSH1 does not support the DSA algorithm.
- **ECDSA key pair**—The SSH server generates only one ECDSA host key pair.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs. For more information about the command for generating key pairs, see public key management commands in *Security Command Reference*.

If the device does not have RSA key pairs with default names, it automatically generates one RSA server key pair and one RSA host key pair when SSH starts. Both key pairs use their default names. The SSH application starts when you execute an SSH server command on the device.

The key modulus length must be less than 2048 bits when you generate the DSA key pair on the SSH server.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

The SSH server operating in FIPS mode supports only ECDSA and RSA key pairs. Do not generate a DSA key pair on the SSH server in FIPS mode.

Procedure

1. Enter system view.

   system-view
2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the SSH service port

About this task

The default port of the SSH service is 22. You can specify another port for the SSH service to improve security of SSH connections.

Restrictions and guidelines

If you modify the SSH port number when the SSH server is enabled, the SSH service is restarted and all SSH connections are terminated after the modification. SSH users must reconnect to the SSH server to access the server.

If you set the SSH port to a well-known port number, the service that uses the well-known port number might fail to start. Well-known port numbers are in the range of 1 to 1024.

Procedure

1. Enter system view.
   system-view
2. Specify the SSH service port.
   ssh server port *port-number*
   By default, the SSH service port is 22.

Enabling the Stelnet server

About this task

After you enable the Stelnet server on the device, a client can log in to the device through Stelnet.

Procedure

1. Enter system view.
   system-view
2. Enable the Stelnet server.
   ssh [**ipv4** | **ipv6**] **server enable**
   By default, the Stelnet server is disabled.

Enabling the SFTP server

About this task

After you enable the SFTP server on the device, a client can log in to the device through SFTP.

Restrictions and guidelines

When acting as an SFTP server, the device does not support SFTP connections initiated by SSH1 clients.

Procedure

1. Enter system view.
   system-view
2. Enable the SFTP server.
   sftp [**ipv4** | **ipv6**] **server enable**
   By default, the SFTP server is disabled.

Enabling the SCP server

About this task

After you enable the SCP server on the device, a client can log in to the device through SCP.

Restrictions and guidelines

When acting as an SCP server, the device does not support SCP connections initiated by SSH1 clients.

Procedure

1. Enter system view.

system-view

2. Enable the SCP server.

   scp [**ipv4** | **ipv6**] **server enable**

   By default, the SCP server is disabled.

Enabling NETCONF over SSH

About this task

After you enable NETCONF over SSH on the device, a client can perform NETCONF operations on the device through a NETCONF-over-SSH connection.

Restrictions and guidelines

When acting as a server in the NETCONF-over-SSH connection, the device does not support connection requests initiated by SSH1 clients.

Procedure

1. Enter system view.

   system-view

2. Enable NETCONF over SSH.

   netconf ssh server enable

   By default, NETCONF over SSH is disabled.

   For more information about NETCONF over SSH commands, see *Network Management and Monitoring Command Reference*.

Configuring the user lines for SSH login

About this task

Depending on the SSH application, an SSH client can be an Stelnet client, SFTP client, SCP client, or NETCONF-over-SSH client.

Only Stelnet and NETCONF-over-SSH clients require the user line configuration. The user line configuration takes effect on the clients at the next login.

Procedure

1. Enter system view.

   system-view

2. Enter VTY user line view.

   line vty *number* [*ending-number*]

3. Set the login authentication mode to scheme.

   authentication-mode scheme

   By default, the authentication mode is **password**.

   For more information about this command, see *Fundamentals Command Reference*.

Configuring a client's host public key

About this task

In publickey authentication, the server compares the SSH username and the client's host public key received from the client with the locally saved SSH username and the client's host public key. If they

are the same, the server checks the digital signature that the client sends. The client generates the digital signature by using the private key that is paired with the client's host public key.

For publickey authentication, password-publickey authentication, or any authentication, you must perform the following tasks:

1. Configure the client's DSA, ECDSA, or RSA host public key on the server.
2. Specify the associated host private key on the client to generate the digital signature.

   If the device acts as an SSH client, specify the public key algorithm on the client. The algorithm determines the associated host private key for generating the digital signature.

Client public key configuration methods

You can configure the client host public key by using the following methods:

- Manually enter the content of a client's host public key on the server.
  a. Display the host public key on the client and record the key.
  b. Type the client's host public key character by character on the server, or use the copy and paste method.

  The manually entered key must be in DER format without being converted. For the displayed key to meet the requirement when the client is an H3C device, use the **display public-key local public** command. The format of the public key displayed in any other way (for example, by using the **public-key local export** command) might be incorrect. If the key is not in correct format, the system discards the key.
- Import the client host public key from a public key file.
  c. Save the client public key file to the server. For example, transfer the client public key file to the server in binary mode through FTP or TFTP.
  d. Import the client public key from the locally saved public key file.

  During the import process, the server automatically converts the host public key to a string in PKCS format.

Restrictions and guidelines

As a best practice, configure no more than 20 SSH client's host public keys on an SSH server.

Import the client's host public key as a best practice.

Entering a client's host public key

1. Enter system view.

   system-view
2. Enter public key view.

   public-key peer *keyname*
3. Configure a client's host public key.

   Enter the content of the client's host public key character by character, or use the copy and paste method.

   When you enter the content of a client's host public key, you can use spaces and carriage returns between characters but the system does not save them. For more information, see "Managing public keys."
4. Exit public key view and save the key.

   peer-public-key end

Importing a client's host public key from the public key file

1. Enter system view.

   system-view
2. Import a client's public key from the public key file.

public-key peer *keyname* **import sshkey** *filename*

Configuring an SSH user

About this task

Configure an SSH user and a local user depending on the authentication method.

- If the authentication method is **publickey**, you must create an SSH user and a local user on the SSH server. The two users must have the same username, so that the SSH user can be assigned the correct working directory and user role.
- If the authentication method is **password**, you must perform one of the following tasks:
  - For local authentication, configure a local user on the SSH server.
  - For remote authentication, configure an SSH user on a remote authentication server, for example, a RADIUS server.

  You do not need to create an SSH user by using the **ssh user** command. However, if you want to display all SSH users, including the password-only SSH users, for centralized management, you can use this command to create them. If such an SSH user has been created, make sure you have specified the correct service type and authentication method.
- If the authentication method is **keyboard-interactive**, **password-publickey**, or **any**, you must create an SSH user on the SSH server and perform one of the following tasks:
  - For local authentication, configure a local user on the SSH server.
  - For remote authentication, configure an SSH user on a remote authentication server, for example, a RADIUS server.

  In either case, the local user or the SSH user configured on the remote authentication server must have the same username as the SSH user.

For information about configuring local users and remote authentication, see "Configuring AAA."

Restrictions and guidelines

If you change the authentication parameters for a logged-in SSH user, the change takes effect on the user at the next login.

When the device operates as an SSH server in FIPS mode, the device does not support authentication method **any** or **publickey**.

For an SFTP or SCP user, the working directory depends on the authentication method.

- If the authentication method is **publickey** or **password-publickey**, the working folder is specified by the **authorization-attribute** command in the associated local user view.
- If the authentication method is **keyboard-interactive** or **password**, the working directory is authorized by AAA.

For an SSH user, the user role also depends on the authentication method.

- If the authentication method is **publickey** or **password-publickey**, the user role is specified by the **authorization-attribute** command in the associated local user view.
- If the authentication method is **keyboard-interactive** or **password**, the user role is authorized by AAA.

For all authentication methods except keyboard-interactive authentication and password authentication, you must specify a client's host public key or digital certificate.

- For a client that sends the user's public key information directly to the server, specify the client's host public key on the server. The specified public key must already exist. For more information about public keys, see "Configuring a client's host public key." If you specify multiple client public keys, the device verifies the user identity by using the public keys in the order they are specified. The user is valid if the user passes one public key check.

- For a client that sends the user's public key information to the server through a digital certificate, specify the PKI domain on the server. This PKI domain verifies the client's digital certificate. For successful verification, the specified PKI domain must have the correct CA certificate. To specify the PKI domain, use the **ssh user** or **ssh server pki-domain** command. For more information about configuring a PKI domain, see "Configuring PKI."

Procedure

1. Enter system view.

   system-view

2. Create an SSH user, and specify the service type and authentication method.

   In non-FIPS mode:

   ssh user *username* **service-type** { **all** | **netconf** | **scp** | **sftp** | **stelnet** } **authentication-type** { **keyboard-interactive** | **password** | { **any** | **password-publickey** | **publickey** } [**assign** { **pki-domain** *domain-name* | **publickey** *keyname*&<1-6> }] }

   In FIPS mode:

   ssh user *username* **service-type** { **all** | **netconf** | **scp** | **sftp** | **stelnet** } **authentication-type** { **keyboard-interactive** | **password** | **password-publickey** [**assign** { **pki-domain** *domain-name* | **publickey** *keyname*&<1-6> }] }

   An SSH server supports up to 1024 SSH users.

Configuring the SSH management parameters

Enabling the SSH server to support SSH1 clients

1. Enter system view.

   system-view

2. Enable the SSH server to support SSH1 clients.

   ssh server compatible-ssh1x enable

   By default, the SSH server does not support SSH1 clients.

   This command is not available in FIPS mode.

Enabling SSH algorithm renegotiation and key re-exchange

1. Enter system view.

   system-view

2. Use one of the following methods or both at the same time to trigger SSH algorithm renegotiation and key re-exchange:

   - Enable SSH algorithm renegotiation and key re-exchange.
     - In non-FIPS mode:

       ssh server key-re-exchange enable [**interval** *interval*]

     - In FIPS mode:

       ssh server key-re-exchange enable [**interval-minutes** *interval*]

     By default, SSH algorithm renegotiation and key re-exchange are disabled.

     The command takes effect only on new SSH connections that are established after the command is executed, and it does not affect existing SSH connections.

   - Configure the traffic threshold that triggers SSH algorithm renegotiation and key re-exchange

     ssh server key-re-exchange traffic-threshold *traffic-threshold*

By default, the traffic threshold that enables SSH algorithm renegotiation and key re-exchange depends on the encryption algorithm for the negotiation:

- For DES and 3DESC encryption algorithms, the traffic threshold that triggers SSH algorithm renegotiation and key re-exchange is 1 GB.
- For AES and SM4 encryption algorithms, the traffic threshold that triggers SSH algorithm renegotiation and key re-exchange is 64 GB.

This feature does not affect the existing SSH connections.

Setting the minimum interval for updating the RSA server key pair

1. Enter system view.

   system-view

2. Set the minimum interval for updating the RSA server key pair.

   ssh server rekey-interval *interval*

   By default, the device does not update the RSA server key pair.

   This command is not available in FIPS mode.

   This configuration takes effect only on SSH1 clients.

Setting the SSH user authentication timeout timer

1. Enter system view.

   system-view

2. Set the SSH user authentication timeout timer.

   ssh server authentication-timeout *time-out-value*

   The default setting is 60 seconds.

   Perform this task to prevent malicious occupation of TCP connections. If a user does not finish the authentication when the timeout timer expires, the connection cannot be established.

Setting the maximum number of SSH authentication attempts

1. Enter system view.

   system-view

2. Set the maximum number of SSH authentication attempts.

   ssh server authentication-retries *retries*

   The default setting is 3.

   Perform this task to prevent malicious hacking of usernames and passwords. If the authentication method is **any**, the total number of publickey authentication attempts and password authentication attempts cannot exceed the upper limit.

Specifying an SSH login control ACL

1. Enter system view.

   system-view

2. Specify an SSH login control ACL.

   IPv4:

   ssh server acl { *advanced-acl-number* | *basic-acl-number* | **mac** *mac-acl-number* }

   IPv6:

   ssh server ipv6 acl { **ipv6** { *advanced-acl-number* | *basic-acl-number* } | **mac** *mac-acl-number* }

   This feature uses an ACL to filter SSH clients that initiate SSH connections to the server. By default, no ACLs are specified and all SSH users can initiate SSH connections to the server.

Only SSH users that match the ACL's permit rules can initiate SSH connections to the server. If the specified ACL does not exist or the ACL contains no rules, no SSH users can initiate SSH connections to the server.

This configuration takes effect only on new SSH connections. It does not affect the existing SSH connections.

Enabling logging for SSH login attempts that are denied by the SSH login control ACL

1. Enter system view.

   system-view

2. Enable logging for SSH login attempts that are denied by the SSH login control ACL.

   ssh server acl-deny-log enable

   By default, logging is disabled for login attempts that are denied by the SSH login control ACL.

   This command enables SSH to generate log messages for SSH login attempts that are denied by the SSH login control ACL and send the messages to the information center.

Setting the DSCP value in the packets that the SSH server sends to SSH clients

1. Enter system view.

   system-view

2. Set the DSCP value in the packets that the SSH server sends to the SSH clients.

   IPv4:

   ssh server dscp *dscp-value*

   IPv6:

   ssh server ipv6 dscp *dscp-value*

   By default, the DSCP value of SSH packets is 48.

   The DSCP value is carried in the ToS field of an IPv4 packet and in the Traffic Class field of an IPv6 packet. It defines the priority of a packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Setting the SFTP connection idle timeout timer

1. Enter system view.

   system-view

2. Set the SFTP connection idle timeout timer.

   sftp server idle-timeout *time-out-value*

   By default, the SFTP connection idle timeout is 10 minutes.

   When the SFTP connection idle timeout timer expires, the system automatically tears the connection down and releases the connection resources.

Setting the maximum number of online SSH users

1. Enter system view.

   system-view

2. Set the maximum number of online SSH users.

   aaa session-limit ssh *max-sessions*

   The default setting is 32.

   When the number of online SSH users reaches the upper limit, the system denies new SSH connection requests. Changing the upper limit does not affect online SSH users.

   For more information about this command, see AAA commands in *Security Command Reference*.

Setting the maximum number of records for SSH user login exceptions

1. Enter system view.

   system-view

2. Set the maximum number of records for SSH user login exceptions.

   ssh exception-record max-number *max-number*

   By default, the maximum number of records for SSH user login exceptions is 10.

   To view more records for SSH user login exceptions, you can use this command to set the maximum number of records.

Setting alarm and recovery thresholds for SSH user login failures in the specified statistics period

1. Enter system view.

   system-view

2. Set alarm and recovery thresholds for SSH user login failures in the specified statistics period.

   ssh server login-failed threshold-alarm upper-limit *report-time* **lower-limit** *resume-time* **period** *period-time*

   By default, the statistics period is 5 minutes, and the SSH user login failure alarm threshold and alarm recovery threshold are 30 and 20, respectively.

   Configure this feature to monitor the SSH user login situation. With this feature configured, the device generates alarms as follows:

   - Generates an alarm when the number of login failures in the specified statistics period reaches or exceeds the alarm threshold.
   - Generates a recovery alarm when the number of login failures in the specified statistics period drops below the alarm recovery threshold from the alarm threshold or a higher value.

Specifying a PKI domain for the SSH server

About this task

The PKI domain specified for the SSH server has the following functions:

- The SSH server uses the PKI domain to send its certificate to the client in the key exchange stage.
- The SSH server uses the PKI domain to authenticate the client's certificate if no PKI domain is specified for the client authentication by using the **ssh user** command.

Procedure

1. Enter system view.

   system-view

2. Specify a PKI domain for the SSH server.

   ssh server pki-domain *domain-name*

   By default, no PKI domain is specified for the SSH server.

Disconnecting SSH sessions

About this task

The device supports concurrent login sessions. To avoid an SSH login user interfering with your configuration, you can disconnect that SSH login user.

Procedure

Execute the following command in user view to disconnect SSH sessions:

free ssh { **user-ip** { *ip-address* | **ipv6** *ipv6-address* } [**port** *port-number*] | **user-pid** *pid-number* | **username** *username* }

Configuring the device as an Stelnet client

Stelnet client tasks at a glance

To configure an Stelnet client, perform the following tasks:

1. Generating local key pairs

   Only required for authentication method **publickey**, **password-publickey**, or **any**.
2. (Optional.) Specifying the source IP address for outgoing SSH packets
3. Establishing a connection to an Stelnet server
4. (Optional.) Deleting server public keys saved in the public key file on the Stelnet client
5. (Optional.) Establishing a connection to an Stelnet server based on Suite B

Generating local key pairs

About this task

You must generate local key pairs on Stelnet clients when the Stelnet server uses the **publickey**, **password-publickey**, or **any** authentication method.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs. For more information about the command for generating key pairs, see public key management commands in *Security Command Reference*.

The key modulus length must be less than 2048 bits when you generate a DSA key pair.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

The Stelnet client operating in FIPS mode supports only ECDSA and RSA key pairs.

Procedure

1. Enter system view.

   system-view
2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the source IP address for outgoing SSH packets

About this task

After you specify the source IP address for outgoing SSH packets on an Stelnet client, the client uses the specified IP address to communicate with the Stelnet server.

Restrictions and guidelines

As a best practice, specify the IP address of a loopback interface as the source address of outgoing SSH packets for the following purposes:

- Ensuring the communication between the Stelnet client and the Stelnet server.
- Improving the manageability of Stelnet clients in authentication service.

Procedure

1. Enter system view.

   system-view

2. Specify the source address for outgoing SSH packets.

   IPv4:

   ssh client source { **interface** *interface-type interface-number* | **ip** *ip-address* }

   By default, an IPv4 Stelnet client uses the primary IPv4 address of the output interface in the matching route as the source address of the outgoing SSH packets.

   IPv6:

   ssh client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, an IPv6 Stelnet client automatically selects a source IPv6 address for outgoing SSH packets in compliance with RFC 3484.

Establishing a connection to an Stelnet server

About this task

Perform this task to enable the Stelnet client feature on the device and establish a connection to the Stelnet server. You can specify the public key algorithm and the preferred encryption, HMAC, and key exchange algorithms to be used during the connection.

To access the server, a client must use the server's host public key to authenticate the server. As a best practice, configure the server's host public key on the device in an insecure network. If the server's host public key is not configured on the client, the client will notify you to confirm whether to continue with the access.

- If you choose to continue, the client accesses the server and downloads the server's host public key. The downloaded public key will be used to authenticate the server in subsequent accesses.

  If the server public key is not specified the when you connect to the server, the device saves the server public key to the public key file. It does not save the server public key to the configuration file.
- If you choose to not continue, the connection cannot be established.

Restrictions and guidelines for establishing a connection to an Stelnet server

An Stelnet client cannot establish connections to both IPv4 and IPv6 Stelnet servers.

Establishing a connection to an IPv4 Stelnet server

Execute the following command in user view to establish a connection with an IPv4 Stelnet server:

In non-FIPS mode:

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** |

aes128-ctr | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

In FIPS mode:

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-ctos-hmac** { **sha2-256** | **sha2-512** } | **prefer-kex** { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-stoc-hmac** { **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

Establishing a connection to an IPv6 Stelnet server

Execute the following command in user view to establish a connection to an IPv6 Stelnet server:

In non-FIPS mode:

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

In FIPS mode:

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-ctos-hmac** { **sha2-256** | **sha2-512** } | **prefer-kex** { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-stoc-hmac** { **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Deleting server public keys saved in the public key file on the Stelnet client

About this task

When the Stelnet client switches to FIPS mode but the locally saved server public key does not comply with FIPS, the client cannot connect to the server. To connect to the server, delete the server public key saved on the client and make sure a FIPS-compliant public key has been generated on the server.

Procedure

1. Enter system view.
   system-view
2. Delete server public keys saved in the public key file on the Stelnet client.
   delete ssh client server-public-key [**server-ip** *ip-address*]

Establishing a connection to an Stelnet server based on Suite B

Execute the following command in user view to establish a connection to an Stelnet server based on Suite B:

IPv4:

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

IPv6:

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Configuring the device as an SFTP client

SFTP client tasks at a glance

To configure an SFTP client, perform the following tasks:

1. Generating local key pairs
   Only required for authentication method **publickey**, **password-publickey**, or **any**.
2. (Optional.) Specifying the source IP address for outgoing SFTP packets
3. Establishing a connection to an SFTP server
4. (Optional.) Deleting server public keys saved in the public key file on the SFTP client
5. (Optional.) Establishing a connection to an SFTP server based on Suite B
6. (Optional.) Working with SFTP directories
7. (Optional.) Working with SFTP files

8. (Optional.) Displaying help information
9. (Optional.) Terminating the connection with the SFTP server

Generating local key pairs

About this task

You must generate local key pairs on SFTP clients when the SFTP server uses the **publickey**, **password-publickey**, or **any** authentication method.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs. For more information about the command for generating key pairs, see public key management commands in *Security Command Reference*.

The key modulus length must be less than 2048 bits when you generate a DSA key pair.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

The SFTP client operating in FIPS mode supports only ECDSA and RSA key pairs.

Procedure

1. Enter system view.

   system-view
2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the source IP address for outgoing SFTP packets

About this task

After you specify the source IP address for outgoing SFTP packets on an SFTP client, the client uses the specified IP address to communicate with the SFTP server.

Restrictions and guidelines

As a best practice, specify the IP address of a loopback interface as the source address of outgoing SFTP packets for the following purposes:

- Ensuring the communication between the SFTP client and the SFTP server.
- Improving the manageability of SFTP clients in authentication service.

Procedure

1. Enter system view.

   system-view
2. Specify the source address for outgoing SFTP packets.

   IPv4:

   sftp client source { **ip** *ip-address* | **interface** *interface-type interface-number* }

   By default, an SFTP client uses the primary IPv4 address of the output interface in the matching route as the source address of the outgoing SFTP packets.

   IPv6:

   sftp client ipv6 source { **ipv6** *ipv6-address* | **interface** *interface-type interface-number* }

By default, an IPv6 SFTP client automatically selects a source IPv6 address for the outgoing SFTP packets in compliance with RFC 3484.

Establishing a connection to an SFTP server

About this task

Perform this task to enable the SFTP client feature on the device and establish a connection to the SFTP server. You can specify the public key algorithm and the preferred encryption, HMAC, and key exchange algorithms to be used during the connection.

To access the server, a client must use the server's host public key to authenticate the server. As a best practice, configure the server's host public key on the device in an insecure network. If the server's host public key is not configured on the client, the client will notify you to confirm whether to continue with the access.

- If you choose to continue, the client accesses the server and downloads the server's host public key. The downloaded public key will be used to authenticate the server in subsequent accesses.

  If the server public key is not specified when you connect to the server, the device saves the server public key to the public key file. It does not save the server public key to the configuration file.
- If you choose to not continue, the connection cannot be established.

Restrictions and guidelines for establishing a connection to an SFTP server

An SFTP client cannot establish connections to both IPv4 and IPv6 SFTP servers.

Establishing a connection to an IPv4 SFTP server

Execute the following command in user view to establish a connection to an IPv4 SFTP server:

In non-FIPS mode:

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

In FIPS mode:

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-ctos-hmac** { **sha2-256** | **sha2-512** } | **prefer-kex** { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-stoc-hmac** { **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | { **public-key** *keyname* |

server-pki-domain *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

Establishing a connection to an IPv6 SFTP server

Execute the following command in user view to establish a connection to an IPv6 SFTP server:

In non-FIPS mode:

sftp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

In FIPS mode:

sftp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-ctos-hmac** { **sha2-256** | **sha2-512** } | **prefer-kex** { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-stoc-hmac** { **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Deleting server public keys saved in the public key file on the SFTP client

About this task

When the SFTP client switches to FIPS mode but the locally saved server public key does not comply with FIPS, the client cannot connect to the server. To connect to the server, delete the server public key saved on the client and make sure a FIPS-compliant public key has been generated on the server.

Procedure

1. Enter system view.

   system-view

2. Delete server public keys saved in the public key file on the SFTP client.

   delete ssh client server-public-key [**server-ip** *ip-address*]

Establishing a connection to an SFTP server based on Suite B

Execute the following command in user view to establish a connection to an SFTP server based on Suite B:

IPv4:

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress** **zlib**] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

IPv6:

sftp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress** **zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Working with SFTP directories

About this task

After you establish a connection to an SFTP server, you can operate directories of the SFTP server.

Changing the working directory on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Change the working directory on the SFTP server.

   cd [*remote-path*]
3. (Optional.) Return to the upper-level directory.

   cdup

Displaying the current working directory on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Display the current working directory on the SFTP server.

   pwd

Displaying files under a directory

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Display files under a directory.
   - **dir** [**-a** | **-l**] [*remote-path*]
   - **ls** [**-a** | **-l**] [*remote-path*]

   The **dir** command has the same function as the **ls** command.

Changing the name of a directory on the SFTP server

1. Enter SFTP client view.

For more information, see "Establishing a connection to an SFTP server."

2. Change the name of a directory on the SFTP server.
   rename *oldname newname*

Creating a new directory on the SFTP server

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Create a new directory on the SFTP server.
   mkdir *remote-path*

Deleting directories on the SFTP server

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Delete one or more directories from the SFTP server.
   rmdir *remote-path*

Working with SFTP files

About this task

After you establish a connection to an SFTP server, you can operate files on the SFTP server.

Changing the name of a file on the SFTP server

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Change the name of a file on the SFTP server.
   rename *old-name new-name*

Downloading a file from the SFTP server and save it locally

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Download a file from the SFTP server and save it locally.
   get *remote-file* [*local-file*]

Uploading a local file to the SFTP server

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Upload a local file to the SFTP server.
   put *local-file* [*remote-file*]

Display files under a directory

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Display files under a directory.
   - **dir** [**-a** | **-l**] [*remote-path*]
   - **ls** [**-a** | **-l**] [*remote-path*]

   The **dir** command has the same function as the **ls** command.

Deleting a file from the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Delete a file from the SFTP server.
   - **`delete`** *`remote-file`*
   - **`remove`** *`remote-file`*

   The **`delete`** command has the same function as the **`remove`** command.

Displaying help information

About this task

After you establish a connection to the SFTP server, you can display the help information of SFTP client commands, including the command syntax and parameter configuration.

Procedure

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Display SFTP client command help information.
   - **`help`**
   - **`?`**

   The **`help`** command has the same function as the **`?`** command.

Terminating the connection with the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Terminate the connection with the SFTP server and return to user view.
   - **`bye`**
   - **`exit`**
   - **`quit`**

   The three commands have the same function.

Configuring the device as an SCP client

SCP client tasks at a glance

To configure an SCP client, perform the following tasks:

1. Generating local key pairs

   Only required for the **publickey**, **password-publickey**, or **any** authentication method.
2. (Optional.) Specifying the source IP address for outgoing SCP packets
3. Establishing a connection to an SCP server
4. (Optional.) Deleting server public keys saved in the public key file on the SCP client
5. (Optional.) Establishing a connection to an SCP server based on Suite B

Generating local key pairs

About this task

You must generate local key pairs on SCP clients when the SCP server uses the **publickey**, **password-publickey**, or **any** authentication method.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs. For more information about the command for generating key pairs, see public key management commands in *Security Command Reference*.

The key modulus length must be less than 2048 bits when you generate a DSA key pair.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

The SCP client operating in FIPS mode supports only ECDSA and RSA key pairs.

Procedure

1. Enter system view.

   system-view

2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the source IP address for outgoing SCP packets

About this task

After you specify the source IP address for outgoing SCP packets on an SCP client, the client uses the specified IP address to communicate with the SCP server.

Restrictions and guidelines

As a best practice, specify the IP address of a loopback interface as the source address of outgoing SCP packets for the following purposes:

- Ensuring the communication between the SCP client and the SCP server.
- Improving the manageability of SCP clients in authentication service.

Procedure

1. Enter system view.

   system-view

2. Specify the source address for outgoing SCP packets.

   IPv4:

   scp client source { **interface** *interface-type interface-number* | **ip** *ip-address* }

   By default, an SCP client uses the primary IPv4 address of the output interface in the matching route as the source address of the outgoing SCP packets.

   IPv6:

   scp client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, an SCP client automatically selects an IPv6 address as the source address of the outgoing packets in compliance with RFC 3484.

Establishing a connection to an SCP server

About this task

Perform this task to enable the SCP client feature on the device, establish a connection to the SCP server, and transfer files with the server. You can specify the public key algorithm and the preferred encryption, HMAC, and key exchange algorithms to be used during the connection.

To access the server, a client must use the server's host public key to authenticate the server. As a best practice, configure the server's host public key on the device in an insecure network. If the server's host public key is not configured on the client, the client will notify you to confirm whether to continue with the access.

- If you choose to continue, the client accesses the server and downloads the server's host public key. The downloaded public key will be used to authenticate the server in subsequent accesses.

  If the server public key is not specified when you connect to the server, the device saves the server public key to the public key file. It does not save the server public key to the configuration file.
- If you choose to not continue, the connection cannot be established.

Restrictions and guidelines for establishing a connection to an SCP server

An SCP client cannot establish connections to both IPv4 and IPv6 SCP servers.

Establishing a connection to an IPv4 SCP server

Execute the following command in user view to connect to an IPv4 SCP server, and transfer files with the server:

In non-FIPS mode:

scp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] { **put** | **get** } *source-file-name* [*destination-file-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** }] * [{ **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

In FIPS mode:

scp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] { **put** | **get** } *source-file-name* [*destination-file-name*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-ctos-hmac** { **sha2-256** | **sha2-512** } | **prefer-kex** { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-stoc-hmac** { **sha2-256** | **sha2-512** }] * [{ **public-key** *keyname* | **server-pki-domain**

domain-name } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

Establishing a connection to an IPv6 SCP server

Execute the following command in user view to connect to an IPv6 SCP server, and transfer files with the server.

In non-FIPS mode:

scp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] { **put** | **get** } *source-file-name* [*destination-file-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress** **zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** }] * [{ **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

In FIPS mode:

scp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] { **put** | **get** } *source-file-name* [*destination-file-name*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress** **zlib** | **prefer-ctos-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-ctos-hmac** { **sha2-256** | **sha2-512** } | **prefer-kex** { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-stoc-hmac** { **sha2-256** | **sha2-512** }] * [{ **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

Deleting server public keys saved in the public key file on the SCP client

About this task

When the SCP client switches to FIPS mode but the locally saved server public key does not comply with FIPS, the client cannot connect to the server. To connect to the server, delete the server public key saved on the client and make sure a FIPS-compliant public key has been generated on the server.

Procedure

1. Enter system view.

   system-view

2. Delete server public keys saved in the public key file on the SCP client.

   delete ssh client server-public-key [**server-ip** *ip-address*]

Establishing a connection to an SCP server based on Suite B

Execute the following command in user view to establish a connection to an SCP server based on Suite B:

IPv4:

scp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] { **put** | **get** } *source-file-name* [*destination-file-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

IPv6:

scp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] { **put** | **get** } *source-file-name* [*destination-file-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

Specifying algorithms for SSH2

About algorithms for SSH2

The SSH2 client and server use the following types of algorithms for algorithm negotiation during the Stelnet, SFTP, or SCP session establishment:

- Key exchange algorithms.
- Public key algorithms.
- Encryption algorithms.
- MAC algorithms.

If you specify algorithms, SSH2 uses only the specified algorithms for algorithm negotiation. The client uses the specified algorithms to initiate the negotiation, and the server uses the matching algorithms to negotiate with the client. If multiple algorithms of the same type are specified, the algorithm specified earlier has a higher priority during negotiation.

Specifying key exchange algorithms for SSH2

1. Enter system view.

   system-view

2. Specify key exchange algorithms for SSH2.

   In non-FIPS mode:

   ssh2 algorithm key-exchange { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } *

   By default, SSH2 uses the **ecdh-sha2-nistp256**, **ecdh-sha2-nistp384**, **dh-group-exchange-sha1**, **dh-group14-sha1**, and **dh-group1-sha1** key exchange algorithms in descending order of priority for algorithm negotiation.

   In FIPS mode:

ssh2 algorithm key-exchange { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } *

By default, SSH2 uses the **ecdh-sha2-nistp256** and **ecdh-sha2-nistp384** key exchange algorithms in descending order of priority for algorithm negotiation.

Specifying public key algorithms for SSH2

1. Enter system view.

   system-view

2. Specify public key algorithms for SSH2.

   In non-FIPS mode:

   ssh2 algorithm public-key { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } *

   By default, SSH2 uses the **x509v3-ecdsa-sha2-nistp256**, **x509v3-ecdsa-sha2-nistp384**, **ecdsa-sha2-nistp256**, **ecdsa-sha2-nistp384**, **rsa**, and **dsa** public key algorithms in descending order of priority for algorithm negotiation.

   In FIPS mode:

   ssh2 algorithm public-key { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } *

   By default, SSH2 uses the **x509v3-ecdsa-sha2-nistp256**, **x509v3-ecdsa-sha2-nistp384**, **ecdsa-sha2-nistp256**, **ecdsa-sha2-nistp384**, and **rsa** public key algorithms in descending order of priority for algorithm negotiation.

Specifying encryption algorithms for SSH2

1. Enter system view.

   system-view

2. Specify encryption algorithms for SSH2.

   In non-FIPS mode:

   ssh2 algorithm cipher { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes128-gcm@openssh** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **aes256-gcm@openssh** | **des-cbc** | **sm4-cbc** } *

   By default, SSH2 uses the **aes128-ctr**, **aes192-ctr**, **aes256-ctr**, **aes128-gcm@openssh**, **aes256-gcm@openssh**, **aes128-gcm**, **aes256-gcm**, **aes128-cbc**, **3des-cbc**, **aes256-cbc**, **des-cbc**, and **sm4-cbc** encryption algorithms in descending order of priority for algorithm negotiation.

   In FIPS mode:

   ssh2 algorithm cipher { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } *

   By default, SSH2 uses the **aes128-gcm@openssh**, **aes256-gcm@openssh**, **aes128-gcm**, and **aes256-gcm** encryption algorithms in descending order of priority for algorithm negotiation.

Specifying MAC algorithms for SSH2

1. Enter system view.

   system-view

2. Specify MAC algorithms for SSH2.

   In non-FIPS mode:

   ssh2 algorithm mac { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } *

   By default, SSH2 uses the **sha2-256**, **sha2-512**, **sha1**, **md5**, **sha1-96**, **md5-96**, and **sm3** MAC algorithms in descending order of priority for algorithm negotiation.

   In FIPS mode:

   ssh2 algorithm mac { **sha2-256** | **sha2-512** } *

   By default, SSH2 uses the **sha2-256** and **sha2-512** MAC algorithms in descending order of priority for algorithm negotiation.

Display and maintenance commands for SSH

Execute **display** commands in any view.

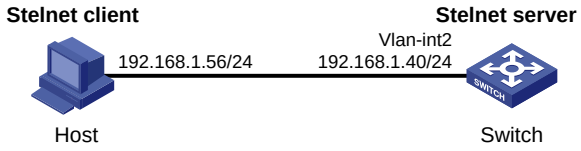
Task	Command
Display the public keys of the local key pairs.	**display public-key local** { **dsa** | **ecdsa** | **rsa** } **public** [**name** *publickey-name*]
Display information about peer public keys.	**display public-key peer** [**brief** | **name** *publickey-name*]
Display the source IP address configuration of the SCP client.	**display scp client source**
Display the source IP address configuration of the SFTP client.	**display sftp client source**
Display server public key information saved in the public key file on the SSH client.	**display ssh client server-public-key** [**server-ip** *ip-address*]
Display the source IP address configuration of the Stelnet client.	**display ssh client source**
Display SSH server status or sessions.	**display ssh server** { **session** | **status** }
Display SSH user information on the SSH server.	**display ssh user-information** [*username*]
Display algorithms used by SSH2 in the algorithm negotiation stage.	**display ssh2 algorithm**
Display records for SSH user login exceptions.	**display ssh exception-record**

For more information about the **display public-key local** and **display public-key peer** commands, see public key management commands in *Security Command Reference*.

Stelnet configuration examples

Unless otherwise noted, devices in the configuration examples operate in non-FIPS mode.

When the device acts as an Stelnet server operating in FIPS mode, only ECDSA and RSA key pairs are supported. Do not generate a DSA key pair on the Stelnet server.



Example: Configuring the device as an Stelnet server (password authentication)

Network configuration

As shown in Figure 1:

- The switch acts as the Stelnet server and uses password authentication to authenticate the Stelnet client. The username and password of the client are saved on the switch.
- The host acts as the Stelnet client, using Stelnet client software (SSH2). After the user on the host logs in to the switch through Stelnet, the user can configure and manage the switch as a network administrator.

Figure 1 Network diagram

Procedure

1. Configure the Stelnet server:

   # Generate RSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

   # Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+.................+..........+...+.
Create the key pair successfully.
```

   # Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
```

```
Create the key pair successfully.
```

Enable the Stelnet server.

```
[Switch] ssh server enable
```

Assign an IP address to VLAN-interface 2. The Stelnet client uses this address as the destination for SSH connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[Switch-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Create a local device management user named **client001**.

```
[Switch] local-user client001 class manage
```

Set a password for local user **client001**.

```
[Switch-luser-manage-client001] password simple 123456TESTplat&!
```

Authorize local user **client001** to use the **SSH** service.

```
[Switch-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role to local user **client001**.

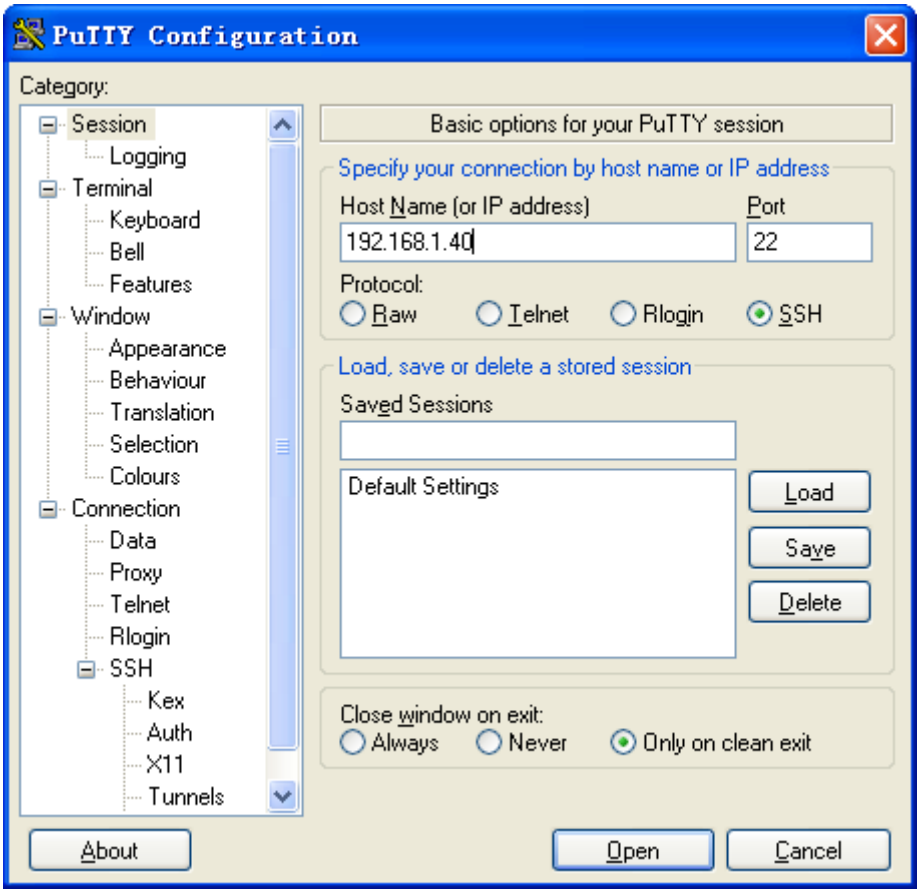
```
[Switch-luser-manage-client001] authorization-attribute user-role network-admin
[Switch-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the service type as **stelnet** and the authentication method as **password** for the user.

```
[Switch] ssh user client001 service-type stelnet authentication-type password
```

2. Establish a connection to the Stelnet server:

There are different types of Stelnet client software, such as PuTTY and OpenSSH. This example uses an Stelnet client that runs PuTTY version 0.58.



To establish a connection to the Stelnet server:

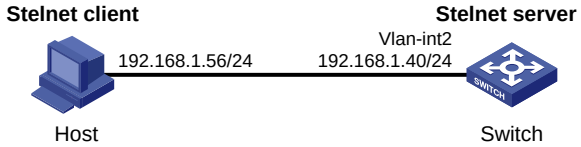
a. Launch PuTTY.exe to enter the interface shown in Figure 2.

b. In the **Host Name (or IP address)** field, enter IP address **192.168.1.40** of the Stelnet server.

c. Click **Open**.

Figure 2 Specifying the host name (or IP address)

a. Enter username **client001** and the password to log in to the Stelnet server.



Example: Configuring the device as an Stelnet server (publickey authentication)

Network configuration

As shown in Figure 3:

- The switch acts as the Stelnet server, and it uses publickey authentication and the RSA public key algorithm.
- The host acts as the Stelnet client, using Stelnet client software (SSH2). After the user on the host logs in to the switch through Stelnet, the user can configure and manage the switch as a network administrator.

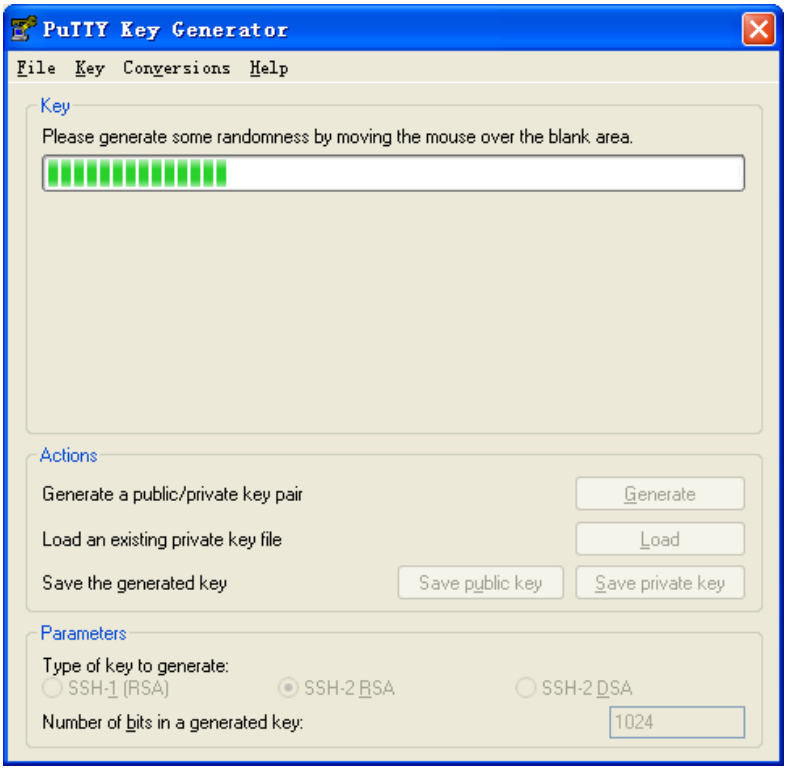
Figure 3 Network diagram

Procedure

In the server configuration, the client's host public key is required. Use the client software to generate RSA key pairs on the client before configuring the Stelnet server.

There are different types of Stelnet client software, such as PuTTY and OpenSSH. This example uses an Stelnet client that runs PuTTY version 0.58.

The configuration procedure is as follows:



1. Generate RSA key pairs on the Stelnet client:
   a. Run PuTTYGen.exe on the client, select **SSH-2 RSA** and click **Generate**.

Figure 4 Generating a key pair on the client

   a. Continue moving the mouse during the key generating process, but do not place the mouse over the green progress bar shown in Figure 5. Otherwise, the progress bar stops moving and the key pair generating progress stops.

Figure 5 Generating process

a. After the key pair is generated, click **Save public key** to save the public key. A file saving window appears.

Figure 6 Saving a key pair on the client

a. Enter a file name (**key.pub** in this example), and click **Save**.

b. On the page shown in Figure 6, click **Save private key** to save the private key.

A confirmation dialog box appears.

c. Click **Yes**.

A file saving window appears.

d. Enter a file name (**private.ppk** in this example), and click **Save**.

e. Transmit the public key file to the server through FTP or TFTP. (Details not shown.)

2. Configure the Stelnet server:

Generate RSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.................................+
...+.................+..........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the Stelnet server.

```
[Switch] ssh server enable
```

Assign an IP address to VLAN-interface 2. The Stelnet client uses this IP address as the destination for SSH connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[Switch-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
```

```
[Switch-line-vty0-63] quit
```

Import the client's public key from the public key file **key.pub** and name it **switchkey**.

```
[Switch] public-key peer switchkey import sshkey key.pub
```

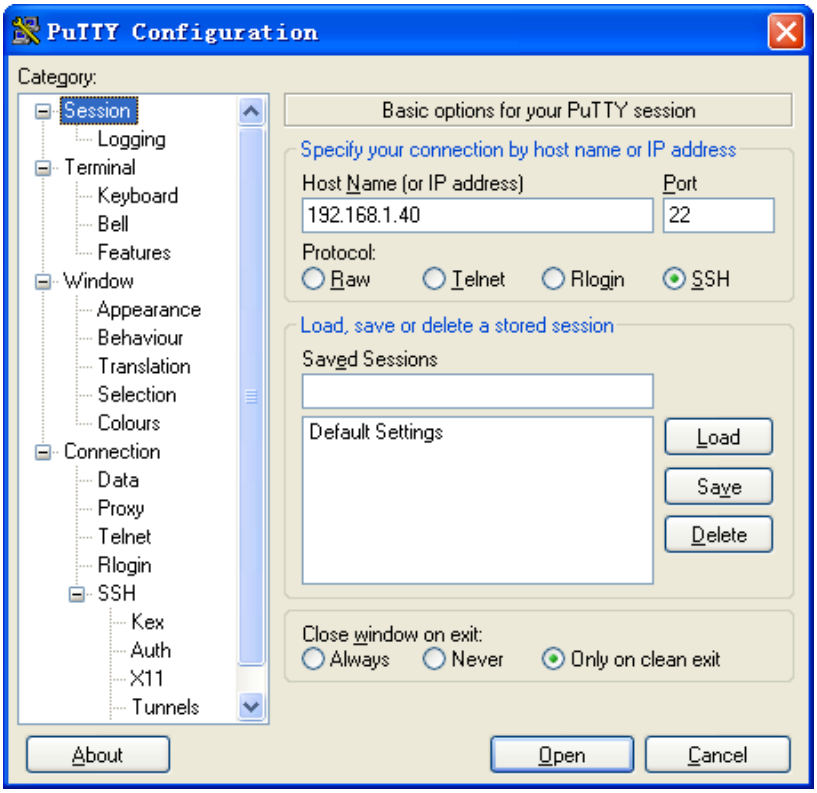
Create an SSH user named **client002**. Specify the authentication method as **publickey** for the user, and assign the public key **switchkey** to the user.

```
[Switch] ssh user client002 service-type stelnet authentication-type publickey assign publickey switchkey
```

Create a local device management user named **client002**.

```
[Switch] local-user client002 class manage
```

Authorize local user **client002** to use the **SSH** service.



```
[Switch-luser-manage-client002] service-type ssh
```

Assign the **network-admin** user role to local user **client002**.

```
[Switch-luser-manage-client002] authorization-attribute user-role network-admin
[Switch-luser-manage-client002] quit
```

3. Specify the private key file and establish a connection to the Stelnet server:
   a. Launch PuTTY.exe on the Stelnet client to enter the interface shown in Figure 7.
   b. In the **Host Name (or IP address)** field, enter IP address **192.168.1.40** of the Stelnet server.

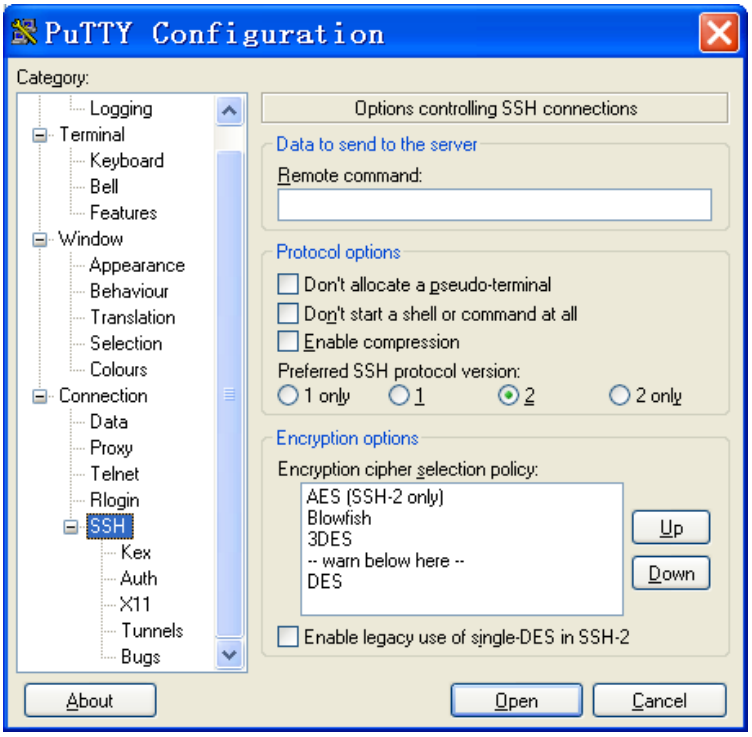


Figure 7 Specifying the host name (or IP address)

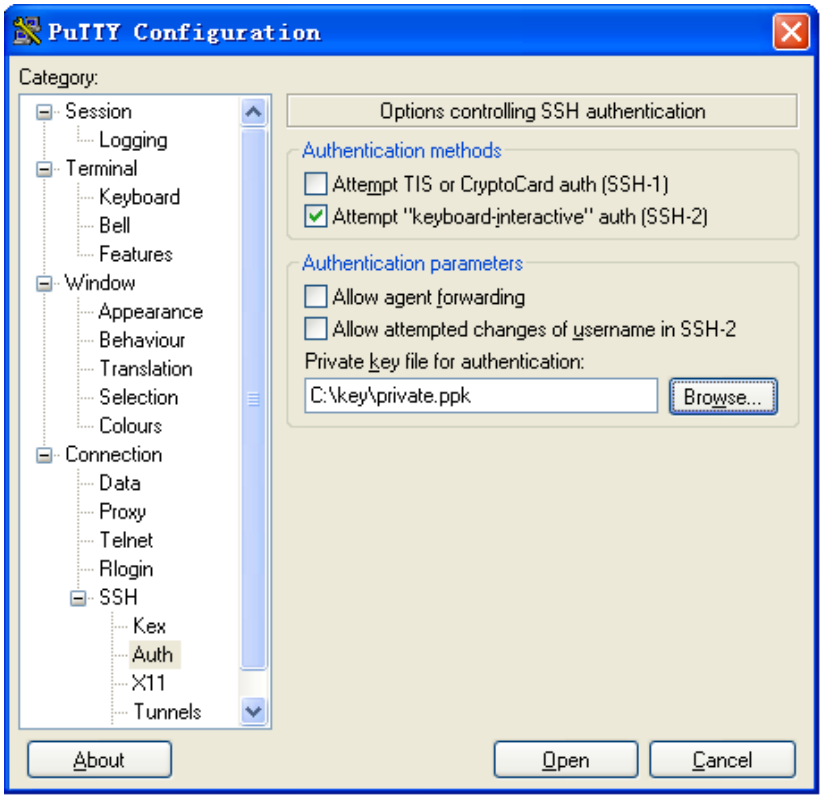
   a. From the navigation tree, select **Connection** > **SSH**.

      The window shown in Figure 8 appears.
   b. Set **Preferred SSH protocol version** to **2**.

Figure 8 Setting the preferred SSH version



a. From the navigation tree, select **Connection** > **SSH** > **Auth**.

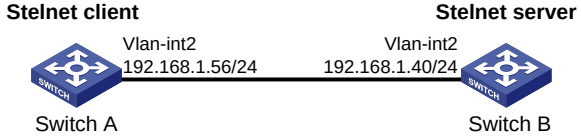
The window shown in Figure 9 appears.

b. Click **Browse…** to open the file selection window, and then select the private key file (**private.ppk** in this example).

c. Click **Open**.

Figure 9 Specifying the private key file

a. Entering username **client002** to log in to the Stelnet server.



Example: Configuring the device as an Stelnet client (password authentication)

Network configuration

As shown in Figure 10:

- Switch B acts as the Stelnet server and uses password authentication to authenticate the Stelnet client. The username and password of the client are saved on Switch B.
- Switch A acts as the Stelnet client. After the user on Switch A logs in to Switch B through Stelnet, the user can configure and manage Switch B as a network administrator.

Figure 10 Network diagram

Procedure

1. Configure the Stelnet server:

Generate RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
```

```
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.................................+
...+.............+.........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[SwitchB] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the Stelnet server.

```
[SwitchB] ssh server enable
```

Assign an IP address to VLAN-interface 2. The Stelnet client uses this address as the destination address of the SSH connection.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[SwitchB] line vty 0 63
[SwitchB-line-vty0-63] authentication-mode scheme
[SwitchB-line-vty0-63] quit
```

Create a local device management user named **client001**.

```
[SwitchB] local-user client001 class manage
```

Set a password for local user **client001**.

```
[SwitchB-luser-manage-client001] password simple 123456TESTplat&!
```

Authorize local user **client001** to use the **SSH** service.

```
[SwitchB-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role to local user **client001**.

```
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the service type as **stelnet** and the authentication method as **password** for the user.

```
[SwitchB] ssh user client001 service-type stelnet authentication-type password
```

Specify public key algorithm **dsa** for SSH2.

```
[SwitchB] ssh2 algorithm public-key dsa
```

2. Establish a connection to the Stelnet server:

Assign an IP address to VLAN-interface 2.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.1.56 255.255.255.0
[SwitchA-Vlan-interface2] quit
[SwitchA] quit
```

- If the client does not have the server's host public key, and is connected to the server for the first time:

  # Establish an SSH connection to server 192.168.1.40. Enter username **client001**, and then enter **y** to continue accessing the server without authenticating the server, and enter **y** to download and save the server's host public key.

```
<SwitchA> ssh2 192.168.1.40
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.1.40 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:y
client001@192.168.1.40's password:

Enter a character ~ and a dot to abort.

******************************************************************************

******************************************************************************
*

<SwitchB>
```

  After you enter the correct password, you can access Switch B successfully. At the next connection attempt, the client automatically authenticates the server by using the server's host public key that is saved on the client, and you only need to enter the password to log in to Switch B.

- If you configure the server's host public key on the client before establishing a connection to the server:

  # Use the **display public-key local dsa public** command on the server to display the server's host public key. (Details not shown.)

  # Enter public key view of the client and copy the host public key of the server to the client.

```
[SwitchA] public-key peer key1
Enter public key view. Return to system view with "peer-public-key end" command.

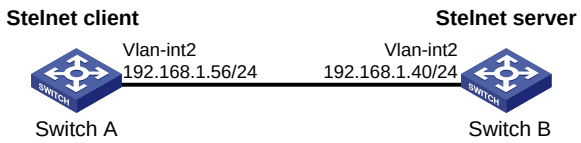
* no decompiling or reverse-engineering shall be allowed.              *
************************************************************************
<SwitchB>
```

After you enter the correct username and password, you can successfully log in to Switch B.



Example: Configuring the device as an Stelnet client (publickey authentication)

Network configuration

As shown in Figure 11:

- Switch B acts as the Stelnet server, and it uses publickey authentication and the DSA public key algorithm.
- Switch A acts as the Stelnet client. After the user on Switch A logs in to Switch B through Stelnet, the user can configure and manage Switch B as a network administrator.

Figure 11 Network diagram

Procedure

In the server configuration, the client's host public key is required. Generate a DSA key pair on the client before configuring the Stelnet server.

1. Configure the Stelnet client:

   # Assign an IP address to VLAN-interface 2.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 192.168.1.56 255.255.255.0
   [SwitchA-Vlan-interface2] quit
   ```

   # Generate a DSA key pair.

   ```
   [SwitchA] public-key local create dsa
   The range of public key modulus is (512 ~ 2048).
   If the key modulus is greater than 512, it will take a few minutes.
   Press CTRL+C to abort.
   Input the modulus length [default = 1024]:
   Generating Keys...
   ```

```
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+................+.........+...+
Create the key pair successfully.
```

Export the DSA host public key to a public key file named **key.pub**.

```
[SwitchA] public-key local export dsa ssh2 key.pub
[SwitchA] quit
```

Transmit the public key file **key.pub** to the server through FTP or TFTP. (Details not shown.)

2. Configure the Stelnet server:

Generate RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key modulus is (512 ~ 4096)
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.......................++++++
...................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+................+.........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[SwitchB] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the Stelnet server.

```
[SwitchB] ssh server enable
```

Assign an IP address to VLAN-interface 2. The Stelnet client uses this address as the destination address for SSH connection.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[SwitchB] line vty 0 63
[SwitchB-line-vty0-63] authentication-mode scheme
```

```
[SwitchB-line-vty0-63] quit
```

Import the peer public key from the public key file **key.pub**, and name it **switchkey**.

```
[SwitchB] public-key peer switchkey import sshkey key.pub
```

Create an SSH user named **client002**. Specify the authentication method as **publickey** for the user. Assign the public key **switchkey** to the user.

```
[SwitchB] ssh user client002 service-type stelnet authentication-type publickey
assign publickey switchkey
```

Create a local device management user named **client002**.

```
[SwitchB] local-user client002 class manage
```

Authorize local user **client002** to use the **SSH** service.

```
[SwitchB-luser-manage-client002] service-type ssh
```

Assign the **network-admin** user role to local user **client002**.

```
[SwitchB-luser-manage-client002] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client002] quit
```

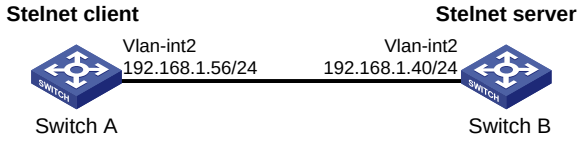
3. Establish an SSH connection to the Stelnet server.

```
<SwitchA> ssh2 192.168.1.40 identity-key dsa
Username: client002
Press CTRL+C to abort.
Connecting to 192.168.1.40 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
Enter a character ~ and a dot to abort.

*****************************************************************************
* Copyright (c) 2004-2017 New H3C Technologies Co., Ltd. All rights reserved.*
* Without the owner's prior written consent,                                *
* no decompiling or reverse-engineering shall be allowed.                   *
*****************************************************************************

<SwitchB>
```

After you enter username **client002** and then enter **y** to continue accessing the server, you can log in to the server successfully.



Example: Configuring Stelnet based on 128-bit Suite B algorithms

Network configuration

As shown in Figure 12:

- Switch B acts as the Stelnet Suite B server (SSH2), and it uses publickey authentication to authenticate the Stelnet client.
- Switch A acts as an Stelnet Suite B client (SSH2). After the user on Switch A logs in to Switch B through the Stelnet Suite B client software, the user can configure and manage Switch B as an administrator.

Figure 12 Network diagram

Procedure

1. Generate the client's certificate and the server's certificate. (Details not shown.)

   You must first configure the certificates of the server and the client because they are required for identity authentication between the two parties.

   In this example, the server's certificate file is **ssh-server-ecdsa256.p12** and the client's certificate file is **ssh-client-ecdsa256.p12**.

2. Configure the Stelnet client:

   You can modify the pkix version of the client software OpenSSH to support Suite B. This example uses an H3C switch as an Stelnet client.

   # Upload the server's certificate file **ssh-server-ecdsa256.p12** and the client's certificate file **ssh-client-ecdsa256.p12** to the Stelnet client through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **server256** for verifying the server's certificate and enter its view.

   ```
   <SwitchA> system-view
   [SwitchA] pki domain server256
   ```

   # Disable CRL checking.

   ```
   [SwitchA-pki-domain-server256] undo crl check enable
   [SwitchA-pki-domain-server256] quit
   ```

   # Import local certificate file **ssh-server-ecdsa256.p12** to PKI domain **server256**.

   ```
   [SwitchA] pki import domain server256 p12 local filename ssh-server-ecdsa256.p12
   The system is going to save the key pair. You must specify a key pair name, which is
   a case-insensitive string of 1 to 64 characters. Valid characters include a to z, A
   to Z, 0 to 9, and hyphens (-).
   Please enter the key pair name[default name: server256]:
   ```

   # Display information about local certificates in PKI domain **server256**.

   ```
   [SwitchA] display pki certificate domain server256 local
   Certificate:
       Data:
           Version: 3 (0x2)
           Serial Number: 3 (0x3)

Assign an IP address to VLAN-interface 2.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.1.56 255.255.255.0
[SwitchA-Vlan-interface2] quit
```

3. Configure the Stelnet server:

Upload the server's certificate file **ssh-server-ecdsa256.p12** and the client's certificate file **ssh-client-ecdsa256.p12** to the Stelnet server through FTP or TFTP. (Details not shown.)

Create a PKI domain named **client256** for verifying the client's certificate and import the file of the client's certificate to this domain. (Details not shown.)

Create a PKI domain named **server256** for the server's certificate and import the file of the server's certificate to this domain. (Details not shown.)

Specify Suite B algorithms for algorithm negotiation.

```
<SwitchB> system-view
[SwitchB] ssh2 algorithm key-exchange ecdh-sha2-nistp256
[SwitchB] ssh2 algorithm cipher aes128-gcm
[SwitchB] ssh2 algorithm public-key x509v3-ecdsa-sha2-nistp256
x509v3-ecdsa-sha2-nistp384
```

Specify **server256** as the PKI domain of the server's certificate.

```
[SwitchB] ssh server pki-domain server256
```

Enable the Stelnet server.

```
[SwitchB] ssh server enable
```

Assign an IP address to VLAN-interface 2.

```
[SwitchB] interface vlan-interface 2
```

```
[SwitchB-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[SwitchB] line vty 0 63
[SwitchB-line-vty0-63] authentication-mode scheme
[SwitchB-line-vty0-63] quit
```

Create a local device management user named **client001**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

```
[SwitchB] local-user client001 class manage
[SwitchB-luser-manage-client001] service-type ssh
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the **publickey** authentication method for the user and specify **client256** as the PKI domain for verifying the client's certificate.

```
[SwitchB] ssh user client001 service-type stelnet authentication-type publickey
assign pki-domain client256
```

4. Establish an SSH connection to the Stelnet server based on the 128-bit Suite B algorithms:

Establish an SSH connection to the server at 192.168.1.40.

```
<SwitchA>  ssh2 192.168.1.40 suite-b 128-bit pki-domain client256 server-pki-domain
server256
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.1.40 port 22.
Enter a character ~ and a dot to abort.

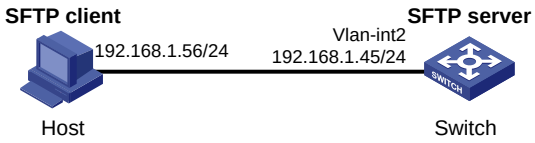
<SwitchB>
```

SFTP configuration examples

Unless otherwise noted, devices in the configuration examples operate in non-FIPS mode.

When the device acts as an SFTP server operating in FIPS mode, only ECDSA and RSA key pairs are supported. Do not generate a DSA key pair on the SFTP server.

Example: Configuring the device as an SFTP server (password authentication)



Network configuration

As shown in Figure 13:

- The switch acts as the SFTP server and uses password authentication to authenticate the SFTP client. The username and password of the client are saved on the switch.

- The host acts as the SFTP client. After the user on the client logs in to the switch through SFTP, the user can perform file management and transfer operations on the switch as a network administrator.

  Figure 13 Network diagram

Procedure

1. Configure the SFTP server:

   # Generate RSA key pairs.

   ```
   <Switch> system-view
   [Switch] public-key local create rsa
   The range of public key modulus is (512 ~ 4096).
   If the key modulus is greater than 512, it will take a few minutes.
   Press CTRL+C to abort.
   Input the modulus length [default = 1024]:
   Generating Keys...
   ........................++++++
   ...................++++++
   ..++++++++
   ............++++++++
   Create the key pair successfully.
   ```

   # Generate a DSA key pair.

   ```
   [Switch] public-key local create dsa
   The range of public key modulus is (512 ~ 2048).
   If the key modulus is greater than 512, it will take a few minutes.
   Press CTRL+C to abort.
   Input the modulus length [default = 1024]:
   Generating Keys...
   .++++++++++++++++++++++++++++++++++++++++++++++++++*
   ........+......+.....+.....................................+
   ...+................+..........+...+
   Create the key pair successfully.
   ```

   # Generate an ECDSA key pair.

   ```
   [Switch] public-key local create ecdsa secp256r1
   Generating Keys...
   .
   Create the key pair successfully.
   ```

   # Enable the SFTP server.

   ```
   [Switch] sftp server enable
   ```

   # Assign an IP address to VLAN-interface 2. The client uses this address as the destination for SSH connection.

   ```
   [Switch] interface vlan-interface 2
   [Switch-Vlan-interface2] ip address 192.168.1.45 255.255.255.0
   [Switch-Vlan-interface2] quit
   ```

Create a local device management user named **client002**.

```
[Switch] local-user client002 class manage
```

Set a password for local user **client002**.

```
[Switch-luser-manage-client002] password simple 123456TESTplat&!
```

Authorize local user **client002** to use the **SSH** service.

```
[Switch-luser-manage-client002] service-type ssh
```

Assign the **network-admin** user role and working directory **flash:/** to local user **client002**.

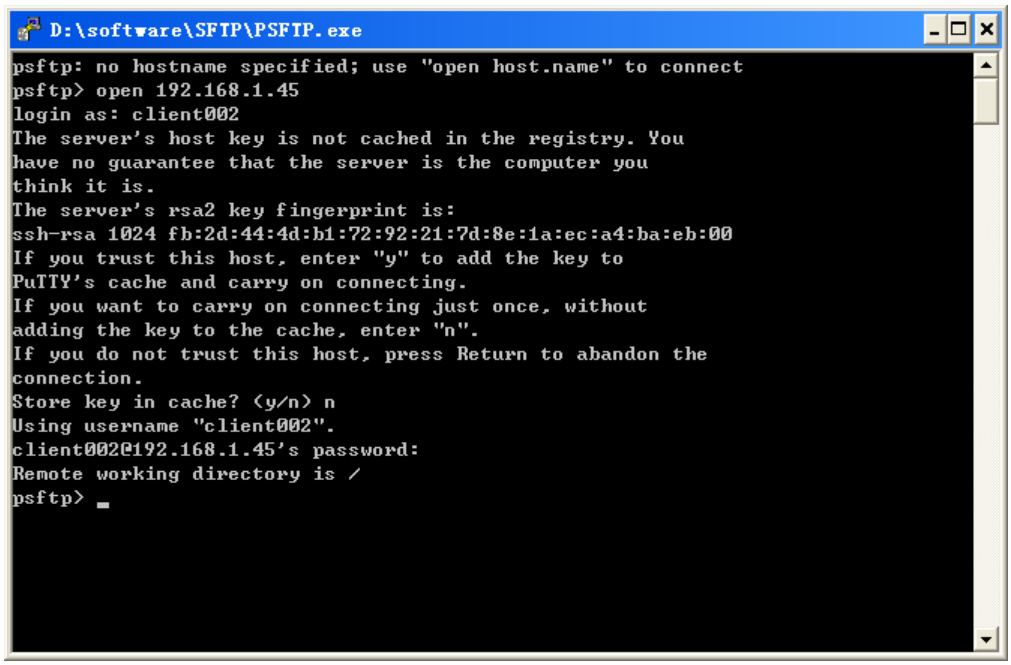
```
[Switch-luser-manage-client002] authorization-attribute user-role network-admin
work-directory flash:/
[Switch-luser-manage-client002] quit
```

Create an SSH user named **client002**. Specify the authentication method as **password** and service type as **sftp** for the user.

```
[Switch] ssh user client002 service-type sftp authentication-type password
```

2. Establish a connection between the SFTP client and the SFTP server:

This example uses an SFTP client that runs PSFTP of PuTTy version 0.58. PSFTP supports only password authentication.



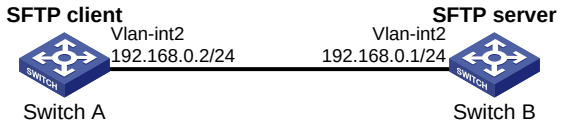
To establish a connection to the SFTP server:

a. Run the **psftp.exe** to launch the client interface shown in Figure 14, and enter the following command:

```
open 192.168.1.45
```

b. Enter username **client002** and the password to log in to the SFTP server.

Figure 14 SFTP client interface



Example: Configuring the device as an SFTP client (publickey authentication)

Network configuration

As shown in Figure 15:

- Switch B acts as the SFTP server, and it uses publickey authentication and the RSA public key algorithm.
- Switch A acts as the SFTP client. After the user on Switch A logs in to Switch B through SFTP, the user can perform file management and transfer operations on Switch B as a network administrator.

Figure 15 Network diagram

Procedure

In the server configuration, the client's host public key is required. Generate RSA key pairs on the client before configuring the SFTP server.

1. Configure the SFTP client:

   # Assign an IP address to VLAN-interface 2.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.0.2 255.255.255.0
[SwitchA-Vlan-interface2] quit
```

   # Generate RSA key pairs.

```
[SwitchA] public-key local create rsa
The range of public key size is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

   # Export the host public key to a public key file named **pubkey**.

```
[SwitchA] public-key local export rsa ssh2 pubkey
[SwitchA] quit
```

   # Transmit the public key file **pubkey** to the server through FTP or TFTP. (Details not shown.)

2. Configure the SFTP server:

   # Generate RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key size is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
```

```
.............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key size is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+.................+..........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[SwitchB] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the SFTP server.

```
[SwitchB] sftp server enable
```

Assign an IP address to VLAN-interface 2. The SSH client uses this address as the destination for SSH connection.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Import the peer public key from the public key file **pubkey**, and name it **switchkey**.

```
[SwitchB] public-key peer switchkey import sshkey pubkey
```

Create an SSH user named **client001**. Specify the service type as **sftp** and the authentication method as **publickey** for the user. Assign the public key **switchkey** to the user.

```
[SwitchB] ssh user client001 service-type sftp authentication-type publickey assign
publickey switchkey
```

Create a local device management user named **client001**.

```
[SwitchB] local-user client001 class manage
```

Authorize local user **client001** to use the **SSH** service.

```
[SwitchB-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role and working directory **flash:/** to local user **client001**.

```
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
work-directory flash:/
[SwitchB-luser-manage-client001] quit
```

3. Establish a connection to the SFTP server:

Establish a connection to the SFTP server and enter SFTP client view.

```
<SwitchA> sftp 192.168.0.1 identity-key rsa
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.0.1 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
sftp>
```

Display files under the current directory of the server, delete file **z**, and verify the result.

```
sftp> dir -l

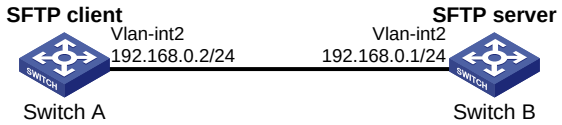
sftp>
```

Exit SFTP client view.

```
sftp> quit
<SwitchA>
```



Example: Configuring SFTP based on 192-bit Suite B algorithms

Network configuration

As shown in Figure 16:

- Switch B acts as the SFTP Suite B server (SSH2), and it uses publickey authentication to authenticate the SFTP client.
- Switch A acts as an SFTP Suite B client (SSH2). After the user on Switch A logs in to Switch B based on the SFTP Suite B client software, the user can manage and transfer files on Switch B as an administrator.

Figure 16 Network diagram

Procedure

1. Generate the client's certificate and the server's certificate. (Details not shown.)

   You must first configure the certificates of the server and the client because they are required for identity authentication between the two parties.

   In this example, the server's certificate file is **ssh-server-ecdsa384.p12** and the client's certificate file is **ssh-client-ecdsa384.p12**.

2. Configure the SFTP client:

   You can modify the pkix version of the client software OpenSSH to support Suite B. This example uses an H3C switch as an SFTP client.

   # Upload the server's certificate file **ssh-server-ecdsa384.p12** and the client's certificate file **ssh-client-ecdsa384.p12** to the SFTP client through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **server384** for verifying the server's certificate and enter its view.

   ```
   <SwitchA> system-view
   [SwitchA] pki domain server384
   ```

   # Disable CRL checking.

   ```
   [SwitchA-pki-domain-server384] undo crl check enable
   [SwitchA-pki-domain-server384] quit
   ```

   # Import local certificate file **ssh-server-ecdsa384.p12** to PKI domain **server384**.

   ```
   [SwitchA] pki import domain server384 p12 local filename ssh-server-ecdsa384.p12
   The system is going to save the key pair. You must specify a key pair name, which is
   a case-insensitive string of 1 to 64 characters. Valid characters include a to z, A
   to Z, 0 to 9, and hyphens (-).
   Please enter the key pair name[default name: server384]:
   ```

   # Display information about local certificates in PKI domain **server384**.

   ```
   [SwitchA] display pki certificate domain server384 local
   ```

```

3. Configure the SFTP server:

   # Upload the server's certificate file **ssh-server-ecdsa384.p12** and the client's certificate file **ssh-client-ecdsa384.p12** to the SFTP server through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **client384** for verifying the client's certificate and import the file of the client's certificate to this domain. (Details not shown.)

   # Create a PKI domain named **server384** for the server's certificate and import the file of the server's certificate to this domain. (Details not shown.)

   # Specify Suite B algorithms for algorithm negotiation.

   ```
   [SwitchB] ssh2 algorithm key-exchange ecdh-sha2-nistp384
   [SwitchB] ssh2 algorithm cipher aes256-gcm
   [SwitchB] ssh2 algorithm public-key x509v3-ecdsa-sha2-nistp384
   ```

   # Specify **server384** as the PKI domain of the server's certificate.

   ```
   [SwitchB] ssh server pki-domain server384
   ```

   # Enable the SFTP server.

   ```
   [SwitchB] sftp server enable
   ```

   # Assign an IP address to VLAN-interface 2.

   ```
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
   [SwitchB-Vlan-interface2] quit
   ```

   # Set the authentication mode to AAA for user lines.

   ```
   [SwitchB] line vty 0 63
   [SwitchB-line-vty0-63] authentication-mode scheme
   [SwitchB-line-vty0-63] quit
   ```

   # Create a local device management user named **client001**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

   ```
   [SwitchB] local-user client001 class manage
   [SwitchB-luser-manage-client001] service-type ssh
   [SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
   [SwitchB-luser-manage-client001] quit
   ```

   # Create an SSH user named **client001**. Specify the **publickey** authentication method for the user and specify **client384** as the PKI domain for verifying the client's certificate.

   ```
   [SwitchB] ssh user client001 service-type sftp authentication-type publickey assign
   pki-domain client384
   ```

4. Establish an SFTP connection to the SFTP server based on the 192-bit Suite B algorithms:

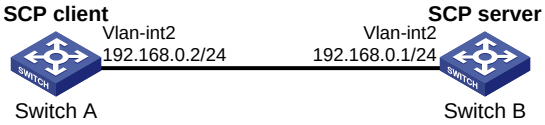
   # Establish an SFTP connection to the server at 192.168.0.1.

   ```
   <SwitchA> sftp 192.168.0.1 suite-b 192-bit pki-domain client384 server-pki-domain
   server384
   Username: client001
   Press CTRL+C to abort.
   Connecting to 192.168.0.1 port 22.
   sftp>
   ```

SCP configuration examples

Unless otherwise noted, devices in the configuration examples operate in non-FIPS mode.

When the device acts as an SCP server operating in FIPS mode, only ECDSA and RSA key pairs are supported. Do not generate a DSA key pair on the SCP server.



Example: Configuring SCP with password authentication

Network configuration

As shown in Figure 17:

- Switch B acts as the SCP server and uses password authentication to authenticate the SCP client. The client's username and password are saved on Switch B.
- Switch A acts as the SCP client. After the user on Switch A logs in to Switch B through SCP, the user can transfer files between switches as a network administrator.

Figure 17 Network diagram

Procedure

1. Configure the SCP server:

   # Generate RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

   # Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+.................+..........+...+.
Create the key pair successfully.
```

   # Generate an ECDSA key pair.

```
[SwitchB] public-key local create ecdsa secp256r1
Generating Keys...
.
```

```
Create the key pair successfully.
```

Enable the SCP server.

```
[SwitchB] scp server enable
```

Configure an IP address for VLAN-interface 2. The client uses this address as the destination for SCP connection.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Create a local device management user named **client001**.

```
[SwitchB] local-user client001 class manage
```

Set a password for local user **client001**.

```
[SwitchB-luser-manage-client001] password simple 123456TESTplat&!
```

Authorize local user **client001** to use the **SSH** service.

```
[SwitchB-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role to local user **client001**.

```
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the service type as **scp** and the authentication method as **password** for the user.

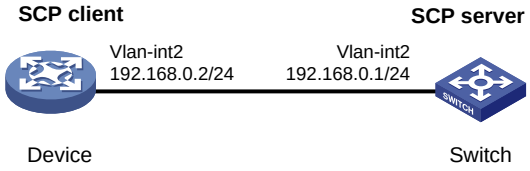
```
[SwitchB] ssh user client001 service-type scp authentication-type password
```

2. Configure an IP address for VLAN-interface 2 on the SCP client.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.0.2 255.255.255.0
[SwitchA-Vlan-interface2] quit
[SwitchA] quit
```

3. Connect to the SCP server, download file **remote.bin** from the server, and save it as a local file named **local.bin**.

```
<SwitchA> scp 192.168.0.1 get remote.bin local.bin
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.0.1 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
client001@192.168.0.1's password:
remote.bin                                    100% 2875     2.8KB/s   00:00
```



Example: Configuring SCP file transfer with a Linux SCP client

Network configuration

As shown in Figure 18, the switch acts as the SCP server and uses password authentication to authenticate the SCP client. The client's username and password are saved on the switch.

The device acts as the SCP client. After the user on the device logs in to the switch through SCP, the user can transfer files with the switch as a network administrator.

Figure 18 Network diagram

Procedure

1. Configure the SCP server:

   # Generate an RSA key pair.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

   # Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.................................+
...+.................+..........+...+.
Create the key pair successfully.
```

   # Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

   # Enable the SCP server.

```
[Switch] scp server enable
```

   # Configure an IP address for VLAN interface 2. The SCP client uses this IP address as the destination address of the SCP connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
[Switch-Vlan-interface2] quit
```

   # Create a local device management user named **client001**. Set a password for the user, authorize the user to use the SSH service, assign the **network-admin** user role to the user, and specify the working directory as **flash:/**.

```
[Switch] local-user client001 class manage
[Switch-luser-manage-client001] password simple 123456TESTplat&!
[Switch-luser-manage-client001] service-type ssh
[Switch-luser-manage-client001] authorization-attribute user-role network-admin
work-directory flash:/
[Switch-luser-manage-client001] quit
```

Configure an SSH user named **client001**, specify the SCP service for the SSH user, and set the authentication method as password. (This step is optional.)

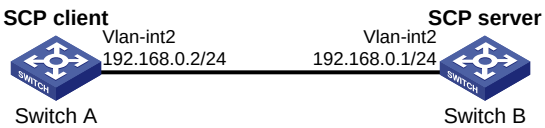
```
[Switch] ssh user client001 service-type scp authentication-type password
```

2. Configure the SCP client:

   The following uses the SCP client running on a Linux system as an example:

   # Connect to the SCP server, download the **remote.bin** file from the server, and save it as a local file named **local.bin**.

```
admin@device:~# scp client001@192.168.0.1:remote.bin local.bin
client001@192.168.0.1's password:
remote.bin                                                    100%   15
     0.0KB/s   00:00
```



Example: Configuring SCP based on Suite B algorithms

Network configuration

As shown in Figure 19:

- Switch B acts as the SCP Suite B server (SSH2), and it uses publickey authentication to authenticate the SCP client.
- Switch A acts as an SCP Suite B client (SSH2). After the user on Switch A logs in to Switch B through the SCP Suite B client software, the user can transfer files between switches as a network administrator.

Figure 19 Network diagram

Procedure

1. Generate the client's certificates and the server's certificates. (Details not shown.)

   You must first configure the certificates of the server and the client because they are required for identity authentication between the two parties.

   In this example, the server's certificate files are **ssh-server-ecdsa256.p12** and **ssh-server-ecdsa384.p12**. The client's certificate files are **ssh-client-ecdsa256.p12** and **ssh-client-ecdsa384.p12**.

2. Configure the SCP client:

   You can modify the pkix version of the client software OpenSSH to support Suite B. This example uses an H3C switch as an SCP client.

   # Upload the server's certificate files (**ssh-server-ecdsa256.p12** and **ssh-server-ecdsa384.p12**) and the client's certificate files (**ssh-client-ecdsa256.p12** and **ssh-client-ecdsa384.p12**) to the SCP client through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **server256** for verifying the server's certificate **ecdsa256** and enter its view.

```
<SwitchA> system-view
[SwitchA] pki domain server256
```

Disable CRL checking.

```
[SwitchA-pki-domain-server256] undo crl check enable
[SwitchA-pki-domain-server256] quit
```

Import local certificate file **ssh-server-ecdsa256.p12** to PKI domain **server256**.

```
[SwitchA] pki import domain server256 p12 local filename ssh-server-ecdsa256.p12
The system is going to save the key pair. You must specify a key pair name, which is
a case-insensitive string of 1 to 64 characters. Valid characters include a to z, A
to Z, 0 to 9, and hyphens (-).
Please enter the key pair name[default name: server256]:
```

Display information about local certificates in PKI domain **server256**.

```
[SwitchA] display pki certificate domain server256 local

Assign an IP address to VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.0.2 255.255.255.0
[SwitchA-Vlan-interface2] quit
```

3. Configure the SCP server:

Upload the server's certificate files (**ssh-server-ecdsa256.p12** and **ssh-server-ecdsa384.p12**) and the client's certificate files (**ssh-client-ecdsa256.p12** and **ssh-client-ecdsa384.p12**) to the SCP server through FTP or TFTP. (Details not shown.)

Create a PKI domain named **client256** for verifying the client's certificate **ecdsa256** and import the file of this certificate to this domain. Create a PKI domain named **server256** for the server's certificate **ecdsa256** and import the file of this certificate to this domain. (Details not shown.)

Create a PKI domain named **client384** for verifying the client's certificate **ecdsa384** and import the file of this certificate to this domain. Create a PKI domain named **server384** for the server's certificate **ecdsa384** and import the file of this certificate to this domain. (Details not shown.)

Specify Suite B algorithms for algorithm negotiation.

```
<SwitchB> system-view
[SwitchB] ssh2 algorithm key-exchange ecdh-sha2-nistp256 ecdh-sha2-nistp384
[SwitchB] ssh2 algorithm cipher aes128-gcm aes256-gcm
[SwitchB] ssh2 algorithm public-key x509v3-ecdsa-sha2-nistp256
x509v3-ecdsa-sha2-nistp384
```

Enable the SCP server.

```
[SwitchB] scp server enable
```

Assign an IP address to VLAN-interface 2.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[SwitchB] line vty 0 63
[SwitchB-line-vty0-63] authentication-mode scheme
[SwitchB-line-vty0-63] quit
```

Create a local device management user named **client001**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

```
[SwitchB] local-user client001 class manage
[SwitchB-luser-manage-client001] service-type ssh
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client001] quit
```

Create a local device management user named **client002**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

```
[SwitchB] local-user client002 class manage
[SwitchB-luser-manage-client002] service-type ssh
[SwitchB-luser-manage-client002] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client002] quit
```

4. Establish an SCP connection to the SCP server:

- Based on the 128-bit Suite B algorithms:

  # Specify **server256** as the PKI domain of the server's certificate.

  ```
  [SwitchB]ssh server pki-domain server256
  ```

  # Create an SSH user **client001**. Specify the **publickey** authentication method for the user and specify **client256** as the PKI domain for verifying the client's certificate.

  ```
  [SwitchB] ssh user client001 service-type scp authentication-type publickey assign pki-domain client256
  ```

  # Establish an SCP connection to the SCP server at 192.168.0.1 based on the 128-bit Suite B algorithms.

  ```
  <SwitchA> scp 192.168.0.1 get src.cfg suite-b 128-bit pki-domain client256 server-pki
  -domain server256
  Username: client001
  Press CTRL+C to abort.
  Connecting to 192.168.0.1 port 22.
  src.cfg                                       100% 4814     4.7KB/s   00:00
  <SwitchA>
  ```

- Based on the 192-bit Suite B algorithms:

  # Specify **server384** as the PKI domain of the server's certificate.

  ```
  [SwitchB] ssh server pki-domain server384
  ```

  # Create an SSH user **client002**. Specify the **publickey** authentication method for the user and specify **client384** as the PKI domain for verifying the client's certificate.

  ```
  [Switch] ssh user client002 service-type scp authentication-type publickey assign pki-domain client384
  ```

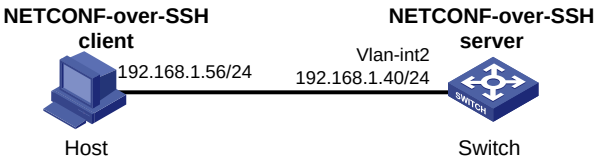
  # Establish an SCP connection to the SCP server at 192.168.0.1 based on the 192-bit Suite B algorithms.

  ```
  <SwitchA> scp 192.168.0.1 get src.cfg suite-b 192-bit pki-domain client384 server-pki
  -domain server384
  Username: client002
  Press CTRL+C to abort.
  Connecting to 192.168.0.1 port 22.
  src.cfg                                       100% 4814     4.7KB/s   00:00
  <SwitchA>
  ```

NETCONF over SSH configuration examples

Unless otherwise noted, devices in the configuration examples are in non-FIPS mode.

When the device acts as a NETCONF-over-SSH server operating in FIPS mode, only ECDSA and RSA key pairs are supported. Do not generate a DSA key pair on the NETCONF-over-SSH server.



Example: Configuring NETCONF over SSH with password authentication

Network configuration

As shown in Figure 20:

- The switch acts as the NETCONF-over-SSH server and uses password authentication to authenticate the client. The client's username and password are saved on the switch.
- The host acts as the NETCONF-over-SSH client, using SSH2 client software. After the user on the host logs in to the switch through NETCONF over SSH, the user can perform NETCONF operations on the switch as a network administrator.

Figure 20 Network diagram

Procedure

Generate RSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
```

```
...+.................+.........+...+.
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable NETCONF over SSH.

```
[Switch] netconf ssh server enable
```

Configure an IP address for VLAN-interface 2. The client uses this address as the destination for NETCONF-over-SSH connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[Switch-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Create a local device management user named **client001**.

```
[Switch] local-user client001 class manage
```

Set a password for local user **client001**.

```
[Switch-luser-manage-client001] password simple 123456TESTplat&!
```

Authorize local user **client001** to use the **SSH** service.

```
[Switch-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role to local user **client001**.

```
[Switch-luser-manage-client001] authorization-attribute user-role network-admin
[Switch-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the service type as **NETCONF** and the authentication method as **password** for the user.

```
[Switch] ssh user client001 service-type netconf authentication-type password
```

Verifying the configuration

Verify that you can perform NETCONF operations after logging in to the switch. (Details not shown.)

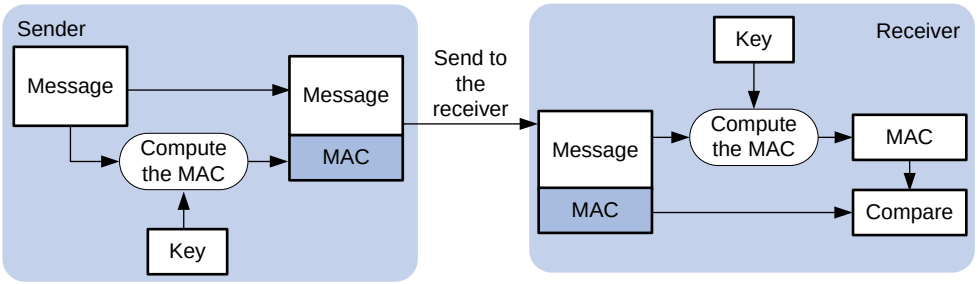
Configuring SSL

About SSL



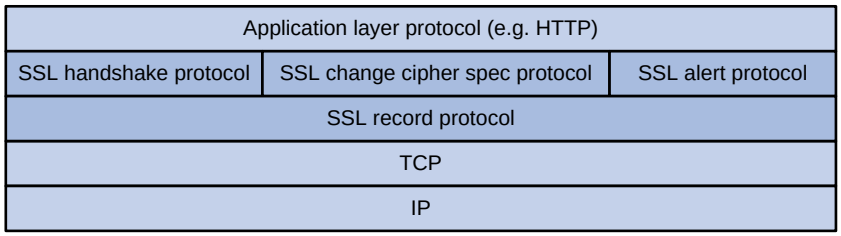
Secure Sockets Layer (SSL) is a cryptographic protocol that provides communication security for TCP-based application layer protocols such as HTTP. SSL has been widely used in applications such as e-business and online banking to provide secure data transmission over the Internet.

SSL security services

SSL provides the following security services:

- **Privacy**—SSL uses a symmetric encryption algorithm to encrypt data. It uses the asymmetric key algorithm of RSA to encrypt the key used by the symmetric encryption algorithm. For more information about RSA, see "Managing public keys."
- **Authentication**—SSL uses certificate-based digital signatures to authenticate the SSL server and client. The SSL server and client obtain digital certificates through PKI. For more information about PKI and digital certificates, see "Configuring PKI."
- **Integrity**—SSL uses the message authentication code (MAC) to verify message integrity. It uses a MAC algorithm and a key to transform a message of any length to a fixed-length message. Any change to the original message will result in a change to the calculated fixed-length message. As shown in Figure 1, the message integrity verification process is as follows:
  - **a.** The sender uses a MAC algorithm and a key to calculate a MAC value for a message. Then, it appends the MAC value to the message and sends the message to the receiver.
  - **b.** The receiver uses the same key and MAC algorithm to calculate a MAC value for the received message, and compares it with the MAC value appended to the message.
  - **c.** If the two MAC values match, the receiver considers the message intact. Otherwise, the receiver considers that the message was tampered with and it discards the message.

Figure 1 MAC algorithm diagram



SSL protocol stack

The SSL protocol stack includes the following protocols:

- SSL record protocol at the lower layer.
- SSL handshake protocol, SSL change cipher spec protocol, and SSL alert protocol at the upper layer.

Figure 2 SSL protocol stack

The following describes the major functions of SSL protocols:

- **SSL record protocol**—Fragments data received from the upper layer, computes and adds MAC to the data, and encrypts the data.
- **SSL handshake protocol**—Negotiates the cipher suite used for secure communication, authenticates the server and client, and securely exchanges the keys between the server and client. The cipher suite that needs to be negotiated includes the symmetric encryption algorithm, key exchange algorithm, and MAC algorithm.
- **SSL change cipher spec protocol**—Notifies the receiver that subsequent packets are to be protected based on the negotiated cipher suite and key.
- **SSL alert protocol**—Sends alert messages to the receiving party. An alert message contains the alert severity level and a description.

SSL protocol versions

SSL protocol versions include SSL 2.0, SSL 3.0, TLS 1.0 (or SSL 3.1), TLS 1.1, and TLS 1.2. Because SSL 3.0 is known to be insecure, you can disable SSL 3.0 for the SSL server to ensure security.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

Restrictions and guidelines: SSL configuration

By default, the SSL server can communicate with clients running all SSL protocol versions. When the server receives an SSL 2.0 Client Hello message from a client, it notifies the client to use a later version for communication.

SSL tasks at a glance

To configure SSL, perform the following tasks:

1. Configuring SSL server settings
   - Configuring an SSL server policy
   - (Optional.) Disabling SSL protocol versions for the SSL server
   - (Optional.) Disabling SSL session renegotiation
2. Configuring SSL client settings

   Configuring an SSL client policy

Configuring an SSL server policy

About this task

An SSL server policy is a set of SSL parameters used by the device when the device acts as the SSL server. An SSL server policy takes effect only after it is associated with an application such as HTTPS.

Procedure

1. Enter system view.

   system-view

2. Create an SSL server policy and enter its view.

   ssl server-policy *policy-name*

3. Specify a PKI domain for the SSL server policy.

   pki-domain *domain-name*

   By default, no PKI domain is specified for an SSL server policy.

   If SSL server authentication is required, you must specify a PKI domain and request a local certificate for the SSL server in the domain.

   For information about configuring a PKI domain, see "Configuring PKI."

4. Specify the cipher suites that the SSL server policy supports.

   In non-FIPS mode:

   ciphersuite { **dhe_rsa_aes_128_cbc_sha** | **dhe_rsa_aes_128_cbc_sha256** | **dhe_rsa_aes_256_cbc_sha** | **dhe_rsa_aes_256_cbc_sha256** | **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **exp_rsa_des_cbc_sha** | **exp_rsa_rc2_md5** | **exp_rsa_rc4_md5** | **rsa_3des_ede_cbc_sha** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_128_gcm_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_aes_256_gcm_sha384** | **rsa_des_cbc_sha** | **rsa_rc4_128_md5** | **rsa_rc4_128_sha** } *

   In FIPS mode:

   ciphersuite { **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256**| **rsa_aes_128_gcm_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_aes_256_gcm_sha384** } *

   By default, an SSL server policy supports all cipher suites.

5. (Optional.) Set the maximum number of sessions that the SSL server can cache and the session cache timeout time.

   session { **cachesize** *size* | **timeout** *time* } *

   By default, the SSL server can cache a maximum of 500 sessions, and the session cache timeout time is 3600 seconds.

6. Enable mandatory or optional SSL client authentication.

   client-verify { **enable** | **optional** }

By default, SSL client authentication is disabled. The SSL server does not perform digital certificate-based authentication on SSL clients.

When authenticating a client by using the digital certificate, the SSL server verifies the certificate chain presented by the client. It also verifies that the certificates in the certificate chain (except the root CA certificate) are not revoked.

7. (Optional.) Enable the SSL server to send the complete certificate chain to the client during SSL negotiation.

   certificate-chain-sending enable

   By default, the SSL server sends the server certificate rather than the complete certificate chain to the client during negotiation.

Configuring an SSL client policy

About this task

An SSL client policy is a set of SSL parameters used by the device when the device acts as the SSL client. The SSL client uses the settings in the client policy to establish a connection to the server. An SSL client policy takes effect only after it is associated with an application such as DDNS. For information about DDNS, see the DNS configuration in *Layer 3—IP Services Configuration Guide*.

Restrictions and guidelines

As a best practice to enhance system security, do not specify SSL 3.0 for the SSL client policy.

Procedure

1. Enter system view.

   system-view

2. Create an SSL client policy and enter its view.

   ssl client-policy *policy-name*

3. Specify a PKI domain for the SSL client policy.

   pki-domain *domain-name*

   By default, no PKI domain is specified for an SSL client policy.

   If SSL client authentication is required, you must specify a PKI domain and request a local certificate for the SSL client in the PKI domain.

   For information about configuring a PKI domain, see "Configuring PKI."

4. Specify the preferred cipher suite for the SSL client policy.

   In non-FIPS mode:

   prefer-cipher { **dhe_rsa_aes_128_cbc_sha** | **dhe_rsa_aes_128_cbc_sha256** | **dhe_rsa_aes_256_cbc_sha** | **dhe_rsa_aes_256_cbc_sha256** | **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **exp_rsa_des_cbc_sha** | **exp_rsa_rc2_md5** | **exp_rsa_rc4_md5** | **rsa_3des_ede_cbc_sha** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_128_gcm_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_aes_256_gcm_sha384** | **rsa_des_cbc_sha** | **rsa_rc4_128_md5** | **rsa_rc4_128_sha** }

   In FIPS mode:

   prefer-cipher { **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** |

ecdhe_rsa_aes_128_gcm_sha256 | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_128_gcm_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_aes_256_gcm_sha384** }

By default:

- In non-FIPS mode, the preferred cipher suite is **rsa_rc4_128_md5**.
- In FIPS mode, the preferred cipher suite is **rsa_aes_128_cbc_sha**.

5. Specify the SSL protocol version for the SSL client policy.

   In non-FIPS mode:

   version { **ssl3.0** | **tls1.0** | **tls1.1** | **tls1.2** }

   In FIPS mode:

   version { **tls1.0** | **tls1.1** | **tls1.2** }

   By default, an SSL client policy uses TLS 1.0.

6. Enable the SSL client to authenticate servers through digital certificates.

   server-verify enable

   By default, SSL server authentication is enabled.

Disabling SSL protocol versions for the SSL server

About this task

To enhance system security, you can disable the SSL server from using specific SSL protocol versions (SSL 3.0, TLS 1.0, and TLS 1.1) for session negotiation.

Restrictions and guidelines

Disabling an SSL protocol version does not affect the availability of earlier SSL protocol versions. For example, if you execute the **ssl version tls1.1 disable** command, TLS 1.1 is disabled but TLS 1.0 is still available for the SSL server.

Procedure

1. Enter system view.

   system-view

2. Disable SSL protocol versions for the SSL server.

   In non-FIPS mode:

   ssl version { **ssl3.0** | **tls1.0** | **tls1.1** } * **disable**

   In FIPS mode:

   ssl version { **tls1.0** | **tls1.1** } * **disable**

   By default:

   - In non-FIPS mode, the SSL server supports SSL 3.0, TLS 1.0, TLS 1.1, and TLS 1.2.
   - In FIPS mode, the SSL server supports TLS 1.0, TLS 1.1, and TLS 1.2.

Disabling SSL session renegotiation

About this task

The SSL session renegotiation feature enables the SSL client and server to reuse a previously negotiated SSL session for an abbreviated handshake.

Disabling session renegotiation causes more computational overhead to the system but it can avoid potential risks.

Restrictions and guidelines

Disable SSL session renegotiation only when explicitly required.

Procedure

1. Enter system view.
   `system-view`
2. Disable SSL session renegotiation.
   `ssl renegotiation disable`
   By default, SSL session renegotiation is enabled.

Display and maintenance commands for SSL

Execute **`display`** commands in any view.

Task	Command
Display SSL client policy information.	**`display ssl client-policy`** [*`policy-name`*]
Display SSL server policy information.	**`display ssl server-policy`** [*`policy-name`*]

Configuring attack detection and prevention

About attack detection and prevention

Attack detection and prevention enables a device to detect attacks by inspecting arriving packets, and to take prevention actions to protect a private network. Prevention actions include:

- Logging.
- Packet dropping.
- Client verification.

Attacks that the device can prevent

This section describes the attacks that the device can detect and prevent.

Single-packet attacks

Single-packet attacks are also known as malformed packet attacks. An attacker typically launches single-packet attacks by using the following methods:

- An attacker sends defective packets to a device, which causes the device to malfunction or crash.
- An attacker sends normal packets to a device, which interrupts connections or probes network topologies.
- An attacker sends a large number of forged packets to a target device, which consumes network bandwidth and causes denial of service (DoS).

Table 1 lists the single-packet attack types that the device can detect and prevent.

Table 1 Types of single-packet attacks

Single-packet attack	Description
ICMP redirect	An attacker sends ICMP redirect messages to modify the victim's routing table. The victim cannot forward packets correctly.
ICMP destination unreachable	An attacker sends ICMP destination unreachable messages to cut off the connections between the victim and its destinations.
ICMP type	A receiver responds to an ICMP packet according to its type. An attacker sends forged ICMP packets of a specific type to affect the packet processing of the victim.
ICMPv6 type	A receiver responds to an ICMPv6 packet according to its type. An attacker sends forged ICMPv6 packets of specific types to affect the packet processing of the victim.
Land	An attacker sends the victim a large number of TCP SYN packets, which contain the victim's IP address as the source and destination IP addresses. This attack exhausts the half-open connection resources on the victim, and locks the victim's system.
Large ICMP packet	An attacker sends large ICMP packets to crash the victim. Large ICMP packets can cause memory allocation error and crash the protocol stack.

Single-packet attack	Description
Large ICMPv6 packet	An attacker sends large ICMPv6 packets to crash the victim. Large ICMPv6 packets can cause memory allocation error and crash the protocol stack.
IP options	An attacker sends IP datagrams in which the IP options are abnormal. This attack intends to probe the network topology. The target system will break down if it is incapable of processing error packets.
IP fragment	An attacker sends the victim an IP datagram with an offset smaller than 5, which causes the victim to malfunction or crash.
IP impossible packet	An attacker sends IP packets whose source IP address is the same as the destination IP address, which causes the victim to malfunction.
Tiny fragment	An attacker makes the fragment size small enough to force Layer 4 header fields into the second fragment. These fragments can pass the packet filtering because they do not hit any match.
Smurf	An attacker sends an ICMP echo request to target networks. In these requests, the destination IP address is a network or broadcast address of a Class A, B, or C subnet, and the source IP address is the victim's IP address. Every receiver on the target networks will send an ICMP echo reply to the victim. The victim will be flooded with replies, and will be unable to provide services. Network congestion might occur.
TCP flag	An attacker sends packets with defective TCP flags to probe the operating system of the target host. Different operating systems process unconventional TCP flags differently. The target system will break down if it processes this type of packets incorrectly.
Traceroute	An attacker uses traceroute tools to probe the topology of the victim network.
WinNuke	An attacker sends Out-Of-Band (OOB) data to the TCP port 139 (NetBIOS) on the victim that runs Windows system. The malicious packets contain an illegal Urgent Pointer, which causes the victim's operating system to crash.
UDP bomb	An attacker sends a malformed UDP packet. The length value in the IP header is larger than the IP header length plus the length value in the UDP header. When the target system processes the packet, a buffer overflow can occur, which causes a system crash.
UDP Snork	An attacker sends a UDP packet with destination port 135 (the Microsoft location service) and source port 135, 7, or 19. This attack causes an NT system to exhaust its CPU.
UDP Fraggle	An attacker sends a large number of packets with source UDP port 7 and destination UDP port 19 (UDP chargen port) to a network. These packets use the victim's IP address as the source IP address. Replies will flood the victim, resulting in DoS.
Teardrop	An attacker sends a stream of overlapping fragments. The victim will crash when it tries to reassemble the overlapping fragments.
Ping of death	An attacker sends the victim an ICMP echo request larger than 65535 bytes that violates the IP protocol. When the victim reassembles the packet, a buffer overflow can occur, which causes a system crash.

Scanning attacks

Scanning is a preintrusion activity used to prepare for intrusion into a network. The scanning allows the attacker to find a way into the target network and to disguise the attacker's identity.

Attackers use scanning tools to probe a network, find vulnerable hosts, and discover services that are running on the hosts. Attackers can use the information to launch attacks.

The device can detect and prevent the IP sweep and port scan attacks. If an attacker performs port scanning from multiple hosts to the target host, distributed port scan attacks occur.

Flood attacks

An attacker launches a flood attack by sending a large number of forged requests to the victim in a short period of time. The victim is too busy responding to these forged requests to provide services for legal users, and a DoS attack occurs.

The device can detect and prevent the following types of flood attacks.

SYN flood attack

A SYN flood attacker exploits the TCP three-way handshake characteristics and makes the victim unresponsive to legal users. An attacker sends a large number of SYN packets with forged source addresses to a server. This causes the server to open a large number of half-open connections and respond to the requests. However, the server will never receive the expected ACK packets. The server is unable to accept new incoming connection requests because all of its resources are bound to half-open connections.

ACK flood attack

An ACK packet is a TCP packet only with the ACK flag set. Upon receiving an ACK packet from a client, the server must search half-open connections for a match.

An ACK flood attacker sends a large number of ACK packets to the server. This causes the server to be busy searching for half-open connections, and the server is unable to process packets for normal services.

SYN-ACK flood attack

Upon receiving a SYN-ACK packet, the server must search for the matching SYN packet it has sent. A SYN-ACK flood attacker sends a large number of SYN-ACK packets to the server. This causes the server to be busy searching for SYN packets, and the server is unable to process packets for normal services.

FIN flood attack

FIN packets are used to shut down TCP connections.

A FIN flood attacker sends a large number of forged FIN packets to a server. The victim might shut down correct connections, or be unable to provide services because it is busy searching for matching connections.

RST flood attack

RST packets are used to abort TCP connections when TCP connection errors occur.

An RST flood attacker sends a large number of forged RST packets to a server. The victim might shut down correct connections, or be unable to provide services because it is busy searching for matching connections.

DNS flood attack

The DNS server processes and replies all DNS queries that it receives.

A DNS flood attacker sends a large number of forged DNS queries. This attack consumes the bandwidth and resources of the DNS server, which prevents the server from processing and replying legal DNS queries.

HTTP flood attack

Upon receiving an HTTP GET request, the HTTP server performs complex operations, including character string searching, database traversal, data reassembly, and format switching. These operations consume a large amount of system resources.

An HTTP flood attacker sends a large number of HTTP GET requests that exceed the processing capacity of the HTTP server, which causes the server to crash.

ICMP flood attack

An ICMP flood attacker sends ICMP request packets, such as ping packets, to a host at a fast rate. Because the target host is busy replying to these requests, it is unable to provide services.

ICMPv6 flood attack

An ICMPv6 flood attacker sends ICMPv6 request packets, such as ping packets, to a host at a fast rate. Because the target host is busy replying to these requests, it is unable to provide services.

UDP flood attack

A UDP flood attacker sends UDP packets to a host at a fast rate. These packets consume a large amount of the target host's bandwidth, so the host cannot provide other services.

TCP fragment attack

An attacker launches TCP fragment attacks by sending attack TCP fragments defined in RFC 1858:

- First fragments in which the TCP header is smaller than 20 bytes.
- Non-first fragments with a fragment offset of 8 bytes (FO=1).

Typically, packet filter detects the source and destination IP addresses, source and destination ports, and transport layer protocol of the first fragment of a TCP packet. If the first fragment passes the detection, all subsequent fragments of the TCP packet are allowed to pass through.

Because the first fragment of attack TCP packets does not hit any match in the packet filter, the subsequent fragments can all pass through. After the receiving host reassembles the fragments, a TCP fragment attack occurs.

To prevent TCP fragment attacks, enable TCP fragment attack prevention to drop attack TCP fragments.

Login dictionary attack

The login dictionary attack is an automated process to attempt to log in by trying all possible passwords from a pre-arranged list of values (the dictionary). Multiple login attempts can occur in a short period of time.

You can configure the login delay feature to slow down the login dictionary attacks. This feature enables the device to delay accepting another login request after detecting a failed login attempt for a user.

Blacklist feature

IP blacklist

The IP blacklist feature is an attack prevention method that filters packets by source IP addresses in blacklist entries. Compared with ACL-based packet filtering, IP blacklist filtering is simpler and provides effective screening at a faster speed.

User blacklist

The user blacklist feature is an attack prevention method that filters packets by source users in blacklist entries. Compared with IP blacklist filtering, user blacklist filtering performs access control on the user level and makes the filtering easy to use.

The user blacklist feature must be used together with the user identification feature. User identification provides the mappings between usernames and IP addresses for the user blacklist.

Attack detection and prevention tasks at a glance

To configure attack detection and prevention, perform the following tasks:

1. Configuring and applying an attack defense policy
   a. Creating an attack defense policy
   b. Configuring an attack defense policy
      Choose the following tasks as needed:
      - Configuring a single-packet attack defense policy
      - Configuring a scanning attack defense policy
      - Configuring a flood attack defense policy
   c. (Optional.) Configuring attack detection exemption
   d. Applying an attack defense policy
      Choose the following tasks as needed:
      - Applying an attack defense policy to an interface
      - Applying an attack defense policy to the device
2. (Optional.) Enabling log non-aggregation for single-packet attack events
3. (Optional.) Configuring TCP fragment attack prevention
   Typically, this feature is separately used.
4. (Optional.) Configuring the blacklist feature
   Use this feature separately or jointly with a scanning attack defense policy.
   - Configuring the IP blacklist feature
   - Configuring the user blacklist feature
5. (Optional.) Configuring the login attack prevention feature
   Typically, this feature is separately used.
   - Configuring login attack prevention
   - Enabling the login delay

Configuring and applying an attack defense policy

Creating an attack defense policy

About this task

An attack defense policy contains a set of attack detection and prevention configuration.

To configure attack defense configuration such as detection signatures and protection actions, you must first create an attack defense policy and enter its view.

Restrictions and guidelines

CAUTION:

The default thresholds for triggering attack prevention might not be appropriate for your network. Set appropriate according to the actual application scenarios. Small thresholds might affect the Internet or webpage access speed. Large thresholds might make your network vulnerable to attacks.

Procedure

1. Enter system view.

   system-view

2. Create an attack defense policy and enter its view.

   attack-defense policy *policy-name*

Configuring a single-packet attack defense policy

About this task

Apply the single-packet attack defense policy to the interface that is connected to the external network.

Single-packet attack detection inspects incoming packets based on the packet signature. If an attack packet is detected, the device can take the following actions:

- Output logs (the default action).
- Drop attack packets.

You can also configure the device to not take any actions.

Procedure

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Configure signature detection for specific single-packet attack types, and specify the actions against the attacks.
   - Configure signature detection for well-known single-packet attacks, and specify the actions against the attacks.

     signature detect { **fraggle** | **fragment** | **impossible** | **land** | **large-icmp** | **large-icmpv6** | **smurf** | **snork** | **tcp-all-flags** | **tcp-fin-only** | **tcp-invalid-flags** | **tcp-null-flag** | **tcp-syn-fin** | **tiny-fragment** | **traceroute** | **udp-bomb** | **winnuke** } [**action** { { **drop** | **logging** } * | **none** }]

     signature detect { **ip-option-abnormal** | **ping-of-death** | **teardrop** } **action** { **drop** | **logging** } *

   - Configure signature detection for ICMP packet attacks, and specify the actions against the attacks.

     signature detect icmp-type { *icmp-type-value* | **address-mask-reply** | **address-mask-request** | **destination-unreachable** | **echo-reply** | **echo-request** | **information-reply** | **information-request** | **parameter-problem** | **redirect** | **source-quench** | **time-exceeded** | **timestamp-reply** | **timestamp-request** } [**action** { { **drop** | **logging** } * | **none** }]

- Configure signature detection for ICMPv6 packet attacks, and specify the actions against the attacks.

  signature detect icmpv6-type { *icmpv6-type-value* | **destination-unreachable** | **echo-reply** | **echo-request** | **group-query** | **group-reduction** | **group-report** | **packet-too-big** | **parameter-problem** | **time-exceeded** } [**action** { { **drop** | **logging** } * | **none** }]

- Configure signature detection for IP option attacks, and specify the actions against the attacks.

  signature detect ip-option { *option-code* | **internet-timestamp** | **loose-source-routing** | **record-route** | **route-alert** | **security** | **stream-id** | **strict-source-routing** } [**action** { { **drop** | **logging** } * | **none** }]

- Configure signature detection for abnormal IPv6 extension header attacks, and specify the actions against the attacks.

  signature detect ipv6-ext-header *ext-header-value* [**action** { { **drop** | **logging** } * | **none** }]

By default, signature detection is not configured for single-packet attacks.

4. (Optional.) Set the maximum length of safe ICMP or ICMPv6 packets.

   signature { **large-icmp** | **large-icmpv6** } **max-length** *length*

   By default, the maximum length of safe ICMP or ICMPv6 packets is 4000 bytes.

5. (Optional.) Specify the actions against single-packet attacks of a specific level.

   signature level { **high** | **info** | **low** | **medium** } **action** { { **drop** | **logging** } * | **none** }

   The default action is **logging** for single-packet attacks of the informational and low levels.

   The default actions are **logging** and **drop** for single-packet attacks of the medium and high levels.

6. (Optional.) Enable signature detection for single-packet attacks of a specific level.

   signature level { **high** | **info** | **low** | **medium** } **detect**

   By default, signature detection is disabled for all levels of single-packet attacks.

Configuring a scanning attack defense policy

About this task

Apply a scanning attack defense policy to the interface that is connected to the external network.

Scanning attack detection inspects the incoming packet rate of connections to the target system. If a source initiates connections at a rate equal to or exceeding the pre-defined threshold, the device can take the following actions:

- Output logs.
- Drop subsequent packets from the IP address of the attacker.

Procedure

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Configure scanning attack detection.

   scan detect level { **high** | **low** | **medium** } **action** { **drop** | **logging** } *

   By default, scanning attack detection is not configured.

Configuring a flood attack defense policy

About this task

Apply a flood attack defense policy to the interface that is connected to the external network to protect internal servers.

Flood attack detection monitors the rate at which connections are initiated to the internal servers.

With flood attack detection enabled, the device is in attack detection state. When the packet sending rate to an IP address reaches the threshold, the device enters prevention state and takes defensive actions, such as logging and dropping subsequent packets. When the rate is below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

Restrictions and guidelines for flood attack detection and prevention

If a device has multiple service cards, the global trigger threshold you set takes effect on each service card. The global trigger threshold of the device is the product of multiplying the value you set by the service card quantity.

You can configure flood attack detection and prevention for a specific IP address. For non-specific IP addresses, the device uses the global attack prevention settings.

Configuring a SYN flood attack defense policy

1. Enter system view.

   system-view
2. Enter attack defense policy view.

   attack-defense policy *policy-name*
3. Enable global SYN flood attack detection.

   syn-flood detect non-specific

   By default, global SYN flood attack detection is disabled.
4. Set the global trigger threshold for SYN flood attack prevention.

   syn-flood threshold *threshold-value*

   The default setting is 1000.
5. Specify global actions against SYN flood attacks.

   syn-flood action { **drop** | **logging** } *

   By default, no global action is specified for SYN flood attacks.
6. Configure IP address-specific SYN flood attack detection.

   syn-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific SYN flood attack detection is not configured.

Configuring an ACK flood attack defense policy

1. Enter system view.

   system-view
2. Enter attack defense policy view.

   attack-defense policy *policy-name*
3. Enable global ACK flood attack detection.

   ack-flood detect non-specific

   By default, global ACK flood attack detection is disabled.
4. Set the global trigger threshold for ACK flood attack prevention.

ack-flood threshold *threshold-value*

The default setting is 1000.

5. Specify global actions against ACK flood attacks.

ack-flood action { **drop** | **logging** } *

By default, no global action is specified for ACK flood attacks.

6. Configure IP address-specific ACK flood attack detection.

ack-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

By default, IP address-specific ACK flood attack detection is not configured.

Configuring a SYN-ACK flood attack defense policy

1. Enter system view.

system-view

2. Enter attack defense policy view.

attack-defense policy *policy-name*

3. Enable global SYN-ACK flood attack detection.

syn-ack-flood detect non-specific

By default, global SYN-ACK flood attack detection is disabled.

4. Set the global trigger threshold for SYN-ACK flood attack prevention.

syn-ack-flood threshold *threshold-value*

The default setting is 1000.

5. Specify global actions against SYN-ACK flood attacks.

syn-ack-flood action { **drop** | **logging** }*

By default, no global action is specified for SYN-ACK flood attacks.

6. Configure IP address-specific SYN-ACK flood attack detection.

syn-ack-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

By default, IP address-specific SYN-ACK flood attack detection is not configured.

Configuring a FIN flood attack defense policy

1. Enter system view.

system-view

2. Enter attack defense policy view.

attack-defense policy *policy-name*

3. Enable global FIN flood attack detection.

fin-flood detect non-specific

By default, global FIN flood attack detection is disabled.

4. Set the global trigger threshold for FIN flood attack prevention.

fin-flood threshold *threshold-value*

The default setting is 1000.

5. Specify global actions against FIN flood attacks.

fin-flood action { **drop** | **logging** } *

By default, no global action is specified for FIN flood attacks.

6. Configure IP address-specific FIN flood attack detection.

fin-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

By default, IP address-specific FIN flood attack detection is not configured.

Configuring an RST flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global RST flood attack detection.

   rst-flood detect non-specific

   By default, global RST flood attack detection is disabled.

4. Set the global trigger threshold for RST flood attack prevention.

   rst-flood threshold *threshold-value*

   The default setting is 1000.

5. Specify global actions against RST flood attacks.

   rst-flood action { **drop** | **logging** } *

   By default, no global action is specified for RST flood attacks.

6. Configure IP address-specific RST flood attack detection.

   rst-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific RST flood attack detection is not configured.

Configuring an ICMP flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global ICMP flood attack detection.

   icmp-flood detect non-specific

   By default, global ICMP flood attack detection is disabled.

4. Set the global trigger threshold for ICMP flood attack prevention.

   icmp-flood threshold *threshold-value*

   The default setting is 1000.

5. Specify global actions against ICMP flood attacks.

   icmp-flood action { **drop** | **logging** } *

   By default, no global action is specified for ICMP flood attacks.

6. Configure IP address-specific ICMP flood attack detection.

   icmp-flood detect ip *ip-address* [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific ICMP flood attack detection is not configured.

Configuring an ICMPv6 flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.
   attack-defense policy *policy-name*
3. Enable global ICMPv6 flood attack detection.
   icmpv6-flood detect non-specific
   By default, global ICMPv6 flood attack detection is disabled.
4. Set the global trigger threshold for ICMPv6 flood attack prevention.
   icmpv6-flood threshold *threshold-value*
   The default setting is 1000.
5. Specify global actions against ICMPv6 flood attacks.
   icmpv6-flood action { **drop** | **logging** } *
   By default, no global action is specified for ICMPv6 flood attacks.
6. Configure IP address-specific ICMPv6 flood attack detection.
   icmpv6-flood detect ipv6 *ipv6-address* [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]
   By default, IP address-specific ICMPv6 flood attack detection is not configured.

Configuring a UDP flood attack defense policy

1. Enter system view.
   system-view
2. Enter attack defense policy view.
   attack-defense policy *policy-name*
3. Enable global UDP flood attack detection.
   udp-flood detect non-specific
   By default, global UDP flood attack detection is disabled.
4. Set the global trigger threshold for UDP flood attack prevention.
   udp-flood threshold *threshold-value*
   The default setting is 1000.
5. Specify global actions against UDP flood attacks.
   udp-flood action { **drop** | **logging** } *
   By default, no global action is specified for UDP flood attacks.
6. Configure IP address-specific UDP flood attack detection.
   udp-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]
   By default, IP address-specific UDP flood attack detection is not configured.

Configuring a DNS flood attack defense policy

1. Enter system view.
   system-view
2. Enter attack defense policy view.
   attack-defense policy *policy-name*
3. Enable global DNS flood attack detection.
   dns-flood detect non-specific
   By default, global DNS flood attack detection is disabled.
4. Set the global trigger threshold for DNS flood attack prevention.

dns-flood threshold *threshold-value*

The default setting is 1000.

5. (Optional.) Specify the global ports to be protected against DNS flood attacks.

   dns-flood port *port-list*

   By default, DNS flood attack prevention protects port 53.

6. Specify global actions against DNS flood attacks.

   dns-flood action { **drop** | **logging** } *

   By default, no global action is specified for DNS flood attacks.

7. Configure IP address-specific DNS flood attack detection.

   dns-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-list*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific DNS flood attack detection is not configured.

Configuring an HTTP flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global HTTP flood attack detection.

   http-flood detect non-specific

   By default, global HTTP flood attack detection is disabled.

4. Set the global trigger threshold for HTTP flood attack prevention.

   http-flood threshold *threshold-value*

   The default setting is 1000.

5. (Optional.) Specify the global ports to be protected against HTTP flood attacks.

   http-flood port *port-list*

   By default, HTTP flood attack prevention protects port 80.

6. Specify global actions against HTTP flood attacks.

   http-flood action { **drop** | **logging** } *

   By default, no global action is specified for HTTP flood attacks.

7. Configure IP address-specific HTTP flood attack detection.

   http-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-list*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific HTTP flood attack detection is not configured.

Configuring attack detection exemption

About this task

The attack defense policy uses the ACL to identify exempted packets. The policy does not check the packets permitted by the ACL. You can configure the ACL to identify packets from trusted servers. The exemption feature reduces the false alarm rate and improves packet processing efficiency. For example, the attack defense policy identifies multicast packets with the same source addresses and different destination addresses as scanning attack packets (for example, OSPF or PIM packets). You can configure an ACL to exempt such packets from attack detection.

Restrictions and guidelines

If an ACL is used for attack detection exemption, only the following match criteria in the ACL permit rules take effect:

- Source IP address.
- Destination IP address.
- Source port.
- Destination port.
- Protocol.
- L3VPN instance.
- The **fragment** keyword for matching non-first fragments.

Procedure

1. Enter system view.
   system-view
2. Enter attack defense policy view.
   attack-defense policy *policy-name*
3. Configure attack detection exemption.
   exempt acl [**ipv6**] { *acl-number* | **name** *acl-name* }
   By default, attack detection exemption is not configured.

Applying an attack defense policy to an interface

1. Enter system view.
   system-view
2. Enter system view.
   interface *interface-type interface-number*
3. Apply an attack defense policy to the interface.
   attack-defense apply policy *policy-name*
   By default, no attack defense policy is applied to the interface.

Applying an attack defense policy to the device

About this task

An attack defense policy applied to the device itself rather than the interfaces detects packets destined for the device and prevents attacks targeted at the device.

A switch uses hardware to implement packet forwarding and uses software to process packets if the packets are destined for the switch. The software does not provide any attack defense features, so you must apply an attack defense policy to the switch to prevent attacks aimed at the switch.

If a device and its interfaces have attack defense policies applied, a packet destined for the device is processed as follows:

1. The policy applied to the receiving interface processes the packet.
2. If the packet is not dropped by the receiving interface, the policy applied to the device processes the packet.

Procedure

1. Enter system view.

```
system-view
```

2. Apply an attack defense policy to the device.
   ```
   attack-defense local apply policy policy-name
   ```
   By default, no attack defense policy is applied to the device.

Enabling log non-aggregation for single-packet attack events

About this task

Log aggregation aggregates multiple logs generated during a period of time and sends one log. Logs that are aggregated must have the following attributes in common:

- Attacks are detected on the same interface or are destined for the device.
- Attack type.
- Attack defense action.
- Source and destination IP addresses.
- VPN instance to which the victim IP address belongs.

Restrictions and guidelines

As a best practice, do not disable log aggregation. A large number of logs will consume the display resources of the console.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable log non-aggregation for single-packet attack events.
   ```
   attack-defense signature log non-aggregate
   ```
   By default, log non-aggregation is disabled for single-packet attack events.

Configuring TCP fragment attack prevention

About this task

The TCP fragment attack prevention feature detects the length and fragment offset of received TCP fragments and drops attack TCP fragments.

Restrictions and guidelines

TCP fragment attack prevention takes precedence over single-packet attack prevention. When both are used, incoming TCP packets are processed first by TCP fragment attack prevention and then by the single-packet attack defense policy.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable TCP fragment attack prevention.
   ```
   attack-defense tcp fragment enable
   ```
   By default, TCP fragment attack prevention is enabled.

Configuring the IP blacklist feature

About this task

The IP blacklist feature filters packets sourced from IP addresses in blacklist entries. If the global blacklist feature is enabled, the blacklist feature is enabled on all interfaces or security zones.

IP blacklist entries can be manually added or dynamically learned:

- You can manually add an IP blacklist entry by using the **blacklist ip** or **blacklist ipv6** command. These entries do not age out by default. You can set an aging time for each entry.
- The device can automatically add IP blacklist entries when collaborating with scanning attack detection. Each dynamically learned IP blacklist entry has an aging time, which is user configurable. Make sure the **block-source** keyword is specified as the scanning attack prevention action. For more information about the scanning attack detection and prevention, see "Configuring a scanning attack defense policy."

Restrictions and guidelines

If the global blacklist feature is enabled, the blacklist feature is enabled on all interfaces.

If the global blacklist feature is disabled, you can enable the blacklist feature on specific interfaces to meet your network requirements.

Procedure

1. Enter system view.

   system-view
2. (Optional.) Enable the global blacklist feature.

   blacklist global enable

   By default, the global blacklist feature is disabled.
3. (Optional.) Add an IP blacklist entry.
   - Add an IPv4 blacklist entry.

     blacklist ip *source-ip-address* [**vpn-instance** *vpn-instance-name*] [**ds-lite-peer** *ds-lite-peer-address*] [**timeout** *minutes*]
   - Add an IPv6 blacklist entry.

     blacklist ipv6 *source-ipv6-address* [**vpn-instance** *vpn-instance-name*] [**timeout** *minutes*]
4. (Optional.) Enable logging for the blacklist feature.

   blacklist logging enable

   By default, logging is disabled for the blacklist feature.
5. Enter interface view.

   interface *interface-type interface-number*
6. Enable the blacklist feature on the interface.

   blacklist enable

   By default, the blacklist feature is disabled on the interface.

Configuring the user blacklist feature

About this task

The user blacklist feature filters packets sourced from users in blacklist entries.

A user blacklist entry can only be manually added by using the **blacklist user** command. A user blacklist entry does not age out by default. You can set an aging time for the entry.

Procedure

1. Enter system view.
   system-view
2. Enable the global blacklist feature.
   blacklist global enable
   By default, the global blacklist feature is disabled.
3. Add a user blacklist entry.
   blacklist user *user-name* [**timeout** *minutes*]
4. (Optional.) Enable logging for the blacklist feature.
   blacklist logging enable
   By default, logging is disabled for the blacklist feature.

Configuring login attack prevention

About this task

The login attack prevention feature detects a login DoS attack if a user fails the maximum number of successive login attempts. The feature triggers the blacklist feature to add the user's IP to the blacklist. Following login attempts from the user is blocked for the block period. For login attack prevention to take effect, you must enable the global blacklist feature.

This feature can effectively prevent login DoS attacks.

Procedure

1. Enter system view.
   system-view
2. Enable login attack prevention.
   attack-defense login enable
   By default, login attack prevention is disabled.
3. Set the maximum number of successive login failures.
   attack-defense login max-attempt *max-attempt*
   The default value is three.
4. Set the block period during which a login attempt is blocked.
   attack-defense login block-timeout *minutes*
   The default value is 60 minutes.
5. Enable the global blacklist feature.
   blacklist global enable
   By default, the global blacklist feature is disabled.

Enabling the login delay

About this task

The login delay feature delays the device from accepting a login request from a user after the user fails a login attempt. This feature can slow down login dictionary attacks.

The login delay feature is independent of the login attack prevention feature.

Procedure

1. Enter system view.
   system-view
2. Enable the login delay feature.
   attack-defense login reauthentication-delay *seconds*
   By default, the login delay feature is disabled. The device does not delay accepting a login request from a user who has failed a login attempt.

Display and maintenance commands for attack detection and prevention

Use the **display** commands in any view and the **reset** commands in user view.

To display and maintain attack detection and prevention:

Task	Command
Display flood attack detection and prevention statistics for an IPv4 address.	**display attack-defense** { **ack-flood** | **dns-flood** | **fin-flood** | **flood** | **http-flood** | **icmp-flood** | **rst-flood** | **syn-ack-flood** | **syn-flood** | **udp-flood** } **statistics ip** [*ip-address* [**vpn** *vpn-instance-name*]] [[**interface** *interface-type interface-number* | **local**] [**slot** *slot-number*]] [**count**]

Task	Command
Display flood attack detection and prevention statistics for an IPv6 address.	**display attack-defense** { **ack-flood** | **dns-flood** | **fin-flood** | **flood** | **http-flood** | **icmpv6-flood** | **rst-flood** | **syn-flood** | **syn-ack-flood** | **udp-flood** } **statistics ipv6** [*ipv6-address* [**vpn** *vpn-instance-name*]] [[**interface** *interface-type interface-number* | **local**] [**slot** *slot-number*]] [**count**]
Display attack defense policy configuration.	**display attack-defense policy** [*policy-name*]

Task	Command
Display information about IPv4 addresses protected by flood attack detection and prevention.	**display attack-defense policy** *policy-name* { **ack-flood** | **dns-flood** | **fin-flood** | **flood** | **http-flood** | **icmp-flood** | **rst-flood** | **syn-ack-flood** | **syn-flood** | **udp-flood** } **ip** [*ip-address* [**vpn** *vpn-instance-name*]] [**slot** *slot-number*] [**count**]
Display information about IPv6 addresses protected by flood attack detection and prevention.	**display attack-defense policy** *policy-name* { **ack-flood** | **dns-flood** | **fin-flood** | **flood** | **http-flood** | **icmpv6-flood** | **rst-flood** | **syn-ack-flood** | **syn-flood** | **udp-flood** } **ipv6** [*ipv6-address* [**vpn** *vpn-instance-name*]] [**slot** *slot-number*] [**count**]

Task	Command
Display information about IPv4 scanning attackers.	**display attack-defense scan attacker ip** [[**interface** *interface-type interface-number* | **local**] [**slot** *slot-number*]] [**count**]
Display information about IPv6 scanning attackers.	**display attack-defense scan attacker ipv6** [[**interface** *interface-type interface-number* | **local**] [**slot** *slot-number*]] [**count**]
Display information about IPv4 scanning attack victims.	**display attack-defense scan victim ip** [[**interface** *interface-type interface-number* | **local**] [**slot** *slot-number*]] [**count**]
Display information about IPv6 scanning attack victims.	**display attack-defense scan victim ipv6** [[**interface** *interface-type interface-number* | **local**] [**slot** *slot-number*]] [**count**]

Task	Command
Display attack detection and prevention statistics on an interface.	**display attack-defense statistics interface** *interface-type interface-number* [**slot** *slot-number*]
Display attack detection and prevention statistics for the device.	**display attack-defense statistics local** [**slot** *slot-number*]
Display manually added IPv4 blacklist entries.	**display blacklist ip** [*source-ip-address* [**vpn-instance** *vpn-instance-name*] [**ds-lite-peer** *ds-lite-peer-address*] | **count**]
Display manually added IPv6 blacklist entries.	**display blacklist ipv6** [*source-ipv6-address* [**vpn-instance** *vpn-instance-name*] | **count**]
Clear flood attack detection and prevention statistics.	**reset attack-defense policy** *policy-name* **flood protected** { **ip** | **ipv6** } **statistics**
Clear attack detection and prevention statistics for an interface.	**reset attack-defense statistics interface** *interface-type interface-number*
Clear attack detection and prevention statistics for the device.	**reset attack-defense statistics local**
Clear dynamic IPv4 blacklist entries.	**reset blacklist ip** { *source-ip-address* [**vpn-instance** *vpn-instance-name*] [**ds-lite-peer** *ds-lite-peer-address*] | **all** }
Clear dynamic IPv6 blacklist entries.	**reset blacklist ipv6** { *source-ipv6-address* [**vpn-instance** *vpn-instance-name*] | **all** }
Clear blacklist statistics.	**reset blacklist statistics**

Attack detection and prevention configuration examples

Example: Configuring attack detection and prevention on the device

Network configuration

Configure attack detection and prevention on the switch (the gateway) to protect against network attacks from the user side or the network side.

- To prevent TCP flag attacks and low level scanning attacks that aim at the switch, enable TCP flag attack prevention and scanning attack prevention. Configure the device to output logs if it detects such attacks.
- To prevent the SYN flood attacks that aim at the external interface of the switch, enable IP address-specific SYN flood attack detection for 192.168.2.1/24. When the device receives 5000 or more SYN packets sent to the protected IP address per second, it outputs logs and drops the packets.
- To prevent the SYN flood attacks that aim at the internal interface of the switch, enable global SYN flood attack detection. When the device receives 2000 or more SYN packets that are destined to the switch but not to the protected IP address per second, it outputs logs.

Figure 1 Network diagram

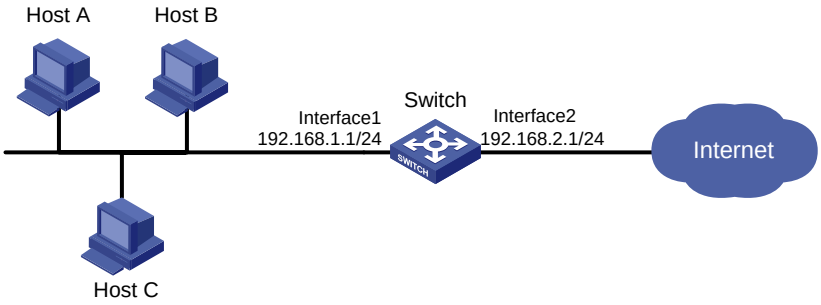

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

Assign IP addresses to interfaces according to the network diagram.

```
<Sysname> system-view
[Sysname] sysname Switch
[Switch] interface gigabitethernet 1/0/1
[Switch-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.255.0
[Switch-GigabitEthernet1/0/1] quit
[Switch] interface gigabitethernet 1/0/2
[Switch-GigabitEthernet1/0/2] ip address 192.168.2.1 255.255.255.0
[Switch-GigabitEthernet1/0/2] quit
```

Create attack defense policy **a1**.

```
[Switch] attack-defense policy a1
```

Enable signature detection for TCP single packet attacks and specify **logging** as the attack prevention action. A TCP packet is identified as an attack packet if it has all flags set, only FIN flag set, invalid flags, no TCP flags set, or both SYN and FIN flags set.

```
[Switch-attack-defense-policy-a1] signature detect tcp-all-flags action logging
[Switch-attack-defense-policy-a1] signature detect tcp-fin-only action logging
[Switch-attack-defense-policy-a1] signature detect tcp-invalid-flags action logging
[Switch-attack-defense-policy-a1] signature detect tcp-null-flag action logging
[Switch-attack-defense-policy-a1] signature detect tcp-syn-fin action logging
```

Enable low level scanning attack detection and specify **logging** as the attack prevention action.

```
[Switch-attack-defense-policy-a1] scan detect level low action logging
```

Enable SYN flood attack detection for 192.168.2.1. Set the threshold for triggering SYN flood attack prevention to 5000 and specify **logging** and **drop** as the attack prevention actions.

```
[Switch-attack-defense-policy-a1] syn-flood detect ip 192.168.2.1 threshold 5000 action
logging drop
```

Enable global SYN flood attack detection, set the global threshold for triggering SYN flood attack prevention to 2000, and specify **logging** as the global attack prevention action.

```
[Switch-attack-defense-policy-a1] syn-flood detect non-specific
[Switch-attack-defense-policy-a1] syn-flood threshold 2000
[Switch-attack-defense-policy-a1] syn-flood action logging
[Switch-attack-defense-policy-a1] quit
```

Apply the attack defense policy to the device.

```
[Switch] attack-defense local apply policy a1
```

Verifying the configuration

Verify that attack defense policy **a1** is correctly configured.

```
[Switch] display attack-defense policy a1
          Attack-defense Policy Information
------------------------------------------------------------------------------
Policy name                       : a1
Applied list                      : Local
------------------------------------------------------------------------------
Exempt IPv4 ACL                   : Not configured
Exempt IPv6 ACL                   : Not configured
------------------------------------------------------------------------------
  Actions: CV-Client verify  BS-Block source  L-Logging  D-Drop  N-None

Signature attack defense configuration:
Signature name                    Defense     Level            Actions
Fragment                          Disabled    low              L
Impossible                        Disabled    medium           L,D
Teardrop                          Disabled    medium           L,D
Tiny fragment                     Disabled    low              L
IP option abnormal                Disabled    medium           L,D
Smurf                             Enabled     medium           L,D
Traceroute                        Disabled    low              L
Ping of death                     Disabled    medium           L,D
Large ICMP                        Disabled    info             L

Example: Configuring IP blacklist

Network configuration

As shown in Figure 2, configure the IP blacklist feature on the router to block packets from the attacker Host D permanently and from Host C for 50 minutes.

Figure 2 Network diagram

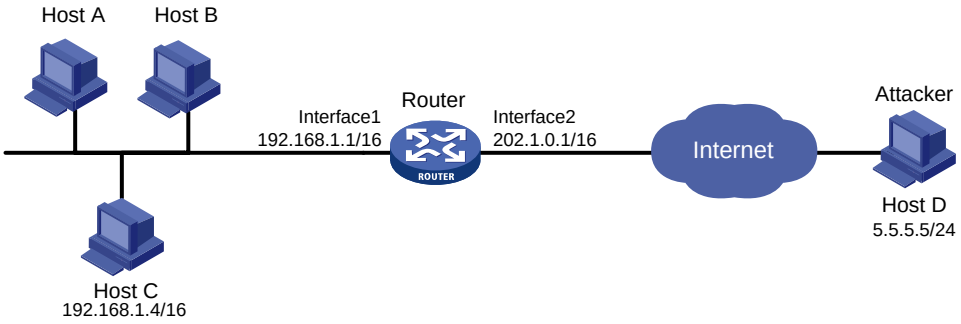

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

Assign IP addresses to interfaces according to the network diagram.

```
<Sysname> system-view
[Sysname] sysname Router
[Router] interface gigabitethernet 1/0/1
[Router-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.0.0
[Router-GigabitEthernet1/0/1] quit
[Router] interface gigabitethernet 1/0/2
[Router-GigabitEthernet1/0/2] ip address 202.1.0.1 255.255.0.0
[Router-GigabitEthernet1/0/2] quit
```

Enable the global blacklist feature.

```
<Router> system-view
[Router] blacklist global enable
```

Add an IPv4 blacklist entry for Host D.

```
[Router] blacklist ip 5.5.5.5
```

Add an IPv4 blacklist entry for Host C and set the blacklist entry aging time to 50 minutes.

```
[Router] blacklist ip 192.168.1.4 timeout 50
```

Verifying the configuration

Verify that the IPv4 blacklist entries are successfully added.

```
<Router> display blacklist ip
IP address      VPN instance   DS-Lite tunnel peer  Type    TTL(sec) Dropped
5.5.5.5         --             --                   Manual  Never    0
192.168.1.4     --             --                   Manual  2989     0
```

Verify that the router drops packets from Host D. (Details not shown.)

Execute the **`undo blacklist ip 5.5.5.5`** command and verify that the router forwards packets from Host D. (Details not shown.)

Verify that the router drops packets from Host C for 50 minutes and forwards packets from Host C after 50 minutes. (Details not shown.)

Configuration files

```
#
interface GigabitEthernet1/0/1
 port link-mode route
 ip address 192.168.1.1 255.255.0.0
#
interface GigabitEthernet1/0/2
 port link-mode route
 ip address 202.1.0.1 255.255.0.0
#
 blacklist ip 5.5.5.5
 blacklist global enable
#
```

Example: Configuring user blacklist

Network configuration

As shown in Figure 3, configure the user blacklist feature on the router to block packets from User C for 50 minutes. The IP address of User C is 1.2.3.4 and the MAC address of User C is 0001-0001-0001.

Figure 3 Network diagram

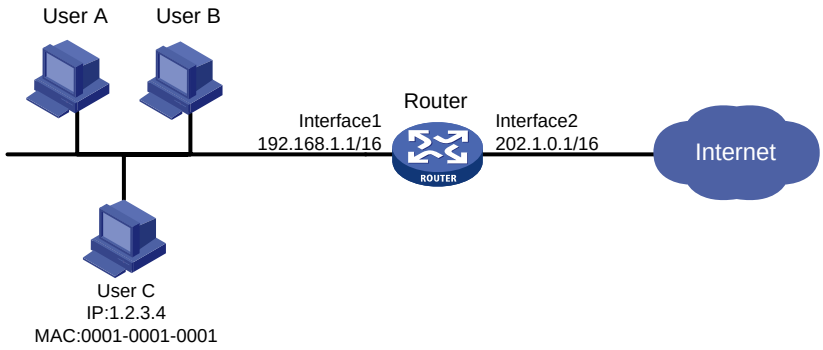

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Assign IP addresses to interfaces according to the network diagram.

```
<Sysname> system-view
[Sysname] sysname Router
[Router] interface gigabitethernet 1/0/1
[Router-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.0.0
[Router-GigabitEthernet1/0/1] quit
[Router] interface gigabitethernet 1/0/2
[Router-GigabitEthernet1/0/2] ip address 202.1.0.1 255.255.0.0
[Router-GigabitEthernet1/0/2] quit
```

2. Configure user identification:

   # Add a network access user named **userc**.

```
<Router> system-view
[Router] local-user userc class network
[Router-luser-network-userc] quit
```

   # Configure a static identity user with username **userc**, IP address 1.2.3.4, and MAC address 0001-0001-0001.

```
[Router] user-identity static-user userc bind ipv4 1.2.3.4 mac 0001-0001-0001
```

   # Enable user identification.

```
[Router] user-identity enable
```

3. Configure the user blacklist feature:

   # Enable the global blacklist feature.

```
[Router] blacklist global enable
```

   # Add a user blacklist entry for user **userc** and set the blacklist entry aging time to 50 minutes.

```
[Router] blacklist user userc timeout 50
```

Verifying the configuration

Verify that the user blacklist entry is successfully added.

```
[Router] display blacklist user
User name      Type    TTL(sec) Dropped
```

```
userc          Manual  2987     0
```

Verify that the router drops packets from User C for 50 minutes and forwards packets from User C after 50 minutes. (Details not shown.)

Configuration files

```
#
interface GigabitEthernet1/0/1
 port link-mode route
 ip address 192.168.1.1 255.255.0.0
#
interface GigabitEthernet1/0/2
 port link-mode route
 ip address 202.1.0.1 255.255.0.0
#
local-user userc class network
 authorization-attribute user-role network-operator
#
 blacklist global enable
#
 user-identity enable
 user-identity static-user userc bind ipv4 1.2.3.4 mac 0001-0001-0001
#
```

Configuring TCP attack prevention 1
About TCP attack prevention 1
Configuring Naptha attack prevention 1

Configuring TCP attack prevention

About TCP attack prevention

TCP attack prevention can detect and prevent attacks that exploit the TCP connection establishment process.

Configuring Naptha attack prevention

About this task

Naptha is a DDoS attack that targets operating systems. It exploits the resources consuming vulnerability in TCP/IP stack and network application process. The attacker establishes a large number of TCP connections in a short period of time and leaves them in certain states without requesting any data. These TCP connections starve the victim of system resources, resulting in a system breakdown.

After you enable Naptha attack prevention, the device periodically checks the number of TCP connections in each state (CLOSING, ESTABLISHED, FIN_WAIT_1, FIN_WAIT_2, and LAST_ACK). If the number of TCP connections in a state exceeds the limit, the device will accelerate the aging of the TCP connections in that state to mitigate the Naptha attack.

Procedure

1. Enter system view.

   system-view

2. Enable Naptha attack prevention.

   tcp anti-naptha enable

   By default, Naptha attack prevention is disabled.

3. (Optional.) Set the maximum number of TCP connections in a state.

   tcp state { **closing** | **established** | **fin-wait-1** | **fin-wait-2** | **last-ack** } **connection-limit** *number*

   By default, the maximum number of TCP connections in each state (CLOSING, ESTABLISHED, FIN_WAIT_1, FIN_WAIT_2, and LAST_ACK) is 50.

   To disable the device from accelerating the aging of the TCP connections in a state, set the value to 0.

4. (Optional.) Set the interval for checking the number of TCP connections in each state.

   tcp check-state interval *interval*

   By default, the interval for checking the number of TCP connections in each state is 30 seconds.

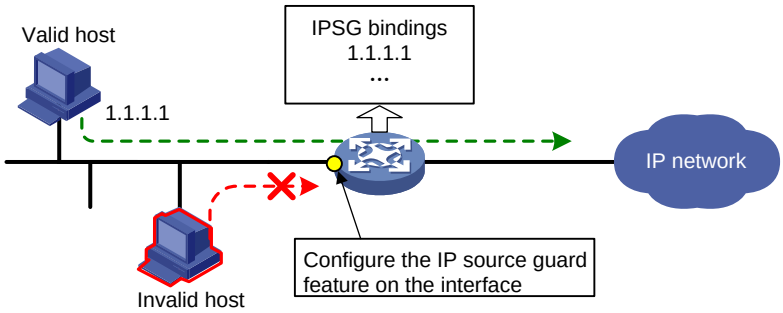
Configuring IP source guard

About IPSG

IP source guard (IPSG) prevents spoofing attacks by using an IPSG binding table to filter out illegitimate packets. This feature is typically configured on user-side interfaces.

IPSG operating mechanism



The IPSG binding table contains bindings that bind IP address, MAC address, VLAN, or any combinations. IPSG uses the bindings to match an incoming packet. If a match is found, the packet is forwarded. If no match is found, the packet is discarded.

IPSG is a per-interface packet filter. Configuring this feature on one interface does not affect packet forwarding on another interface.

IPSG bindings can be static or dynamic.

As shown in Figure 1, IPSG forwards only the packets that match an IPSG binding.

Figure 1 IPSG application

Static IPSG bindings

Static IPSG bindings are configured manually. They are suitable for scenarios where few hosts exist on a LAN and their IP addresses are manually configured. For example, you can configure a static IPSG binding on an interface that connects to a server. This binding allows the interface to receive packets only from the server.

Static IPSG bindings on an interface implement the following functions:

- Filter incoming IPv4 or IPv6 packets on the interface.
- Cooperate with ARP attack detection in IPv4 for user validity checking. For information about ARP attack detection, see "Configuring ARP attack protection."
- Cooperate with ND attack detection in IPv6 for user validity checking. For information about ND attack detection, see "Configuring ND attack defense."

Static IPSG bindings can be global or interface-specific.

- **Global static binding**—Binds the IP address and MAC address in system view. The binding takes effect on all interfaces to filter packets for user spoofing attack prevention.
- **Interface-specific static binding**—Binds the IP address, MAC address, VLAN, or any combination of the items in interface view. The binding takes effect only on the interface to check the validity of users who are attempting to access the interface.

Dynamic IPSG bindings

IPSG automatically obtains user information from other modules to generate dynamic bindings. A dynamic IPSG binding can contain MAC address, IPv4 or IPv6 address, VLAN tag, ingress interface, and binding type. The binding type identifies the source module for the binding, such as DHCP snooping, DHCPv6 snooping, DHCP relay agent, or DHCPv6 relay agent.

For example, DHCP-based IPSG bindings are suitable for scenarios where hosts on a LAN obtain IP addresses through DHCP. IPSG is configured on the DHCP server, the DHCP snooping device, or the DHCP relay agent. It generates dynamic bindings based on the client bindings on the DHCP server, the DHCP snooping entries, or the DHCP relay entries. IPSG allows only packets from the DHCP clients to pass through.

Dynamic IPv4SG

Dynamic bindings generated based on different source modules are for different usages:

Interface types	Source modules	Binding usage
Layer 2 Ethernet interface	DHCP snooping 802.1X	Packet filtering.
	ARP snooping	For cooperation with modules (such as the MFF module) to provide security services.
Layer 3 Ethernet interface VLAN interface	DHCP relay agent	Packet filtering.
	DHCP server	For cooperation with modules (such as the authorized ARP module) to provide security services.

For more information about 802.1X, see "Configuring 802.1X." For information about ARP snooping, DHCP snooping, DHCP relay, and DHCP server, see *Layer 3—IP Services Configuration Guide*.

Dynamic IPv6SG

Dynamic IPv6SG bindings generated based on different source modules are for different usages:

Interface types	Source modules	Binding usage
Layer 2 Ethernet interface	DHCPv6 snooping ND snooping 802.1X	Packet filtering.
Layer 3 Ethernet interface VLAN interface	DHCPv6 relay agent ND RA prefix entry recording	Packet filtering.
	DHCPv6 server	Reporting bindings to the controller to provide online and offline user information.

For more information about DHCPv6 snooping, see *Layer 3—IP Services Configuration Guide*. For more information about ND snooping, see IPv6 basics configuration in *Layer 3—IP Services Configuration Guide*. For more information about ND RA prefix entry recording, see IPv6 neighbor discovery in *Layer 3—IP Services Configuration Guide.* For more information about DHCPv6 relay agent, see *Layer 3—IP Services Configuration Guide*. For more information about DHCPv6 server, see *Layer 3—IP Services Configuration Guide.*

IPSG bindings synchronized by routing protocols

In addition to static and dynamic IPSG bindings, the device also supports IPSG bindings synchronized by routing protocols (such as BGP) from remote devices. These bindings are called remote IPSG bindings. By default, the remote IPSG bindings do not have interface information and cannot be used for packet filtering. When users roam from remote devices to the local device, the device learns interface information for the remote IPSG bindings through ARP or ND entries of the users. Then, the device converts the remote IPSG bindings into local IPSG bindings and uses these bindings for packet filtering.

For more information about BGP, see BGP overview in *Layer 3—IP Routing Configuration Guide*.

IPSG tasks at a glance

To configure IPSG, perform the following tasks:

1. To configure IPv4SG, perform the following tasks:
   a. Enabling IPv4SG
   b. (Optional.) Configuring a static IPv4SG binding
   c. (Optional.) Excluding IPv4 packets from IPSG filtering
   d. (Optional.) Enabling IPv4SG alarming
2. To configure IPv6SG, perform the following tasks:
   a. Enabling IPv6SG
   b. (Optional.) Configuring a static IPv6SG binding
   c. (Optional.) Enabling IPv6SG alarming
3. Enabling SNMP notifications for IPSG

Configuring the IPv4SG feature

Enabling IPv4SG

About this task

When you enable IPSG on an interface, the static and dynamic IPSG are both enabled.

- Static IPv4SG uses static bindings configured by using the **ip source binding** command. For more information, see "Configuring a static IPv4SG binding."
- Dynamic IPv4SG generates dynamic bindings from related source modules. IPv4SG uses the bindings to filter incoming IPv4 packets based on the matching criteria specified in the **ip verify source** command.

Restrictions and guidelines

To implement dynamic IPv4SG, make sure 802.1X, ARP snooping, DHCP snooping, DHCP relay agent, or DHCP server operates correctly on the network.

Enabling IPv4SG on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   The following interface types are supported:

- Layer 2 Ethernet interface.
- Layer 3 Ethernet interface.
- VLAN interface.

3. Enable the IPv4SG feature.

   ip verify source { **ip-address** | **ip-address** **mac-address** | **mac-address** }

   By default, the IPv4SG feature is disabled on an interface.

Configuring a static IPv4SG binding

About this task

You can configure global static and interface-specific static IPv4SG bindings. Interface-specific static and dynamic bindings take priority over global static bindings. An interface first uses the static and dynamic bindings on the interface to match packets. If no match is found, the interface uses the global bindings.

Restrictions and guidelines

Global static bindings take effect on all interfaces on the device.

To configure a static IPv4SG binding for the ARP attack detection feature, make sure the following conditions are met:

- The **ip-address** *ip-address* option, the **mac-address** *mac-address* option, and the **vlan** *vlan-id* option must be specified.
- ARP attack detection must be enabled for the specified VLAN.

Configuring a global static IPv4SG binding

1. Enter system view.

   system-view

2. Configure a global static IPv4SG binding.

   ip source binding ip-address *ip-address* **mac-address** *mac-address*

Configuring a static IPv4SG binding on an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

   The following interface types are supported:

   - Layer 2 Ethernet interface.
   - Layer 3 Ethernet interface.
   - VLAN interface.

3. Configure a static IPv4SG binding.

   ip source binding { **ip-address** *ip-address* | **ip-address** *ip-address* **mac-address** *mac-address* | **mac-address** *mac-address* } [**vlan** *vlan-id*]

   You can configure the same static IPv4SG binding on different interfaces.

Excluding IPv4 packets from IPSG filtering

About this task

By default, IPv4SG processes all incoming IPv4 packets on an interface and discards the packets that do not match IPSG bindings. To allow specific IPv4 packets that do not match any IPSG binding to pass through the interface, you can specify source items of the packets for IPSG filtering exemption. All IPv4 packets with the specified source items are forwarded without being processed by IPSG.

Procedure

1. Enter system view.

   system-view

2. Exclude IPv4 packets with the specified source items from IPSG filtering.

   ip verify source exclude vlan *start-vlan-id* [to *end-vlan-id*]

   By default, no excluded source items are configured.

   You can execute this command multiple times to specify multiple excluded VLANs. The specified excluded VLANs cannot overlap.

Enabling IPv4SG alarming

About this task

This feature monitors the number of packets dropped by IPv4SG per second. When the packet dropping rate reaches or exceeds the alarm threshold, the device generates an alarm log. When the packet dropping rate drops below the alarm threshold, the device generates an alarm-cleared log.

Restrictions and guidelines

Do not enable this feature in a VLAN and an Ethernet interface belonging to the VLAN at the same time.

Procedure

1. Enter system view.

   system-view

2. Enter interface view or VLAN view.

   - Enter interface view.

     interface *interface-type interface-number*

   - Enter VLAN view.

     vlan *vlan-id*

3. Enable IPv4SG alarming on the interface.

   ip verify source alarm [*alarm-threshold*]

   By default, IPv4SG alarming is disabled on an interface.

Configuring the IPv6SG feature

Enabling IPv6SG

About this task

When you enable IPv6SG on an interface, the static and dynamic IPv6SG are both enabled.

- Static IPv6SG uses static bindings configured by using the **ipv6 source binding** command. For more information, see "Configuring a static IPv6SG binding."
- Dynamic IPv6SG generates dynamic bindings from related source modules. IPv6SG uses the bindings to filter incoming IPv6 packets based on the matching criteria specified in the **ipv6 verify source** command.

Restrictions and guidelines

To implement dynamic IPv6SG, make sure DHCPv6 snooping, DHCPv6 relay agent, or ND snooping operates correctly on the network.

Enabling IPv6SG on an interface

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*

   The following interface types are supported:

   - Layer 2 Ethernet interface.
   - Layer 3 Ethernet interface.
   - VLAN interface.
3. Enable the IPv6SG feature.

   ipv6 verify source { **ip-address** | **ip-address mac-address** | **mac-address** }

   By default, the IPv6SG feature is disabled on an interface.

Configuring a static IPv6SG binding

About this task

You can configure global static and interface-specific static IPv6SG bindings. Interface-specific static and dynamic bindings take priority over global static bindings. An interface first uses the static and dynamic bindings on the interface to match packets. If no match is found, the interface uses the global bindings.

Restrictions and guidelines

Global static bindings take effect on all interfaces on the device.

To configure a static IPv6SG binding for the ND attack detection feature, the **vlan** *vlan-id* option must be specified, and ND attack detection must be enabled for the specified VLAN.

If you configure both a static IPv6SG binding and VLAN mapping on a Layer 2 Ethernet interface, the interface forwards packets as follows:

- If you configure VLAN mapping and then configure a static IPv6SG binding and specify the original VLAN for the binding, the interface forwards packets based on the original VLAN.
- If you configure a static IPv6SG binding and specify a VLAN for the binding and then configure VLAN mapping, the interface forwards packets without considering the VLAN.

Configuring a global static IPv6SG binding

1. Enter system view.

   system-view
2. Configure a global static IPv6SG binding.

   ipv6 source binding ip-address *ipv6-address* **mac-address** *mac-address*

Configuring a static IPv6SG binding on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   The following interface types are supported:
   - Layer 2 Ethernet interface.
   - Layer 3 Ethernet interface.
   - VLAN interface.
3. Configure a static IPv6SG binding.
   ipv6 source binding { **ip-address** *ipv6-address* | **ip-address** *ipv6-address* **mac-address** *mac-address* | **mac-address** *mac-address* } [**vlan** *vlan-id*]
   You can configure the same static IPv6SG binding on different interfaces.

Setting the maximum number of IPv6SG bindings on an interface

About this task

You can set the maximum number of IPv6SG bindings on an interface to limit the total number of static and dynamic IPv6SG bindings on the interface. If the upper limit is reached, no more IPv6SG bindings can be added on the interface.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view.
   interface *interface-type interface-number*
3. Set the maximum number of IPv6SG bindings on the interface.
   ipv6 verify source max-entries *number*
   By default, the maximum number of IPv6SG bindings is not limited on an interface.

Enabling IPv6SG alarming

About this task

This feature enables the device to monitor the number of packets dropped by IPv6SG per second. When the packet dropping rate reaches or exceeds the alarm threshold, the device generates an alarm log. When the packet dropping rate drops below the alarm threshold, the device generates an alarm-cleared log.

Restrictions and guidelines

Do not enable this feature in a VLAN and an Ethernet interface belonging to the VLAN at the same time.

Procedure

1. Enter system view.
   system-view
2. Enter interface view or VLAN view.

- Enter interface view.
  interface *interface-type interface-number*
- *Enter VLAN view.*
  vlan *vlan-id*

3. Enable IPv6SG alarming on the interface.
   ipv6 verify source alarm [*alarm-threshold*]
   By default, IPv6SG alarming is disabled on an interface.

Enabling SNMP notifications for IPSG

About this task

To report critical IPSG events to an NMS, enable SNMP notifications for IPSG. For example, If you enable the device to generate notifications when the number of packets dropped by IPSG per second on an interface has reached, exceeded, or dropped below the alarm threshold, the device works as follows:

- When the number of packets dropped by IPSG per second on an interface is equal to or greater than the IPv4SG or IPv6SG alarm threshold, the device sends a notification.
- When the number of packets dropped by IPSG per second on an interface drops below the IPv4SG or IPv6SG alarm threshold, the device reports a threshold recovery event.

To set the IPv4 or IPv6SG alarm threshold, execute the **ip verify source alarm** or **ipv6 verify source alarm** command, respectively.

For SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP and information center configuration, see *Network Management and Monitoring Guide*.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for IPSG.
   snmp-agent trap enable ipsg [**drop-threshold**]
   By default, SNMP notifications for IPSG are enabled.

Display and maintenance commands for IPSG

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display IPv4SG bindings.	**display ip source binding** [**static** | [**vpn-instance** *vpn-instance-name*] [**arp-snooping-vlan** | **dhcp-relay** | **dhcp-server** | **dhcp-snooping** | **dot1x** | **remote**]] [**ip-address** *ip-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display local IPv4SG bindings that can be synchronized by routing protocols.	**display ip source binding-local** [**interface** *interface-type interface-number*] [**dhcp-relay**] [**ip-address** *ip-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]

Task	Command
Display remote IPv4SG bindings synchronized by routing protocols.	**display ip source binding-remote** [**router-id** *router-id*] [**dhcp-relay**] [**ip-address** *ip-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]
Display statistics about local and remote IPv4SG bindings that routing protocols synchronize.	**display ip source binding statistics**
Display source items that have been configured to be excluded from IPSG filtering.	**display ip verify source excluded** [**vlan** *start-vlan-id* [**to** *end-vlan-id*]] [**slot** *slot-number*]
Display IPv6SG address bindings.	**display ipv6 source binding** [**static** | [**vpn-instance** *vpn-instance-name*] [**dhcpv6-relay** | **dhcpv6-server** | **dhcpv6-snooping** | **dot1x** | **nd-snooping-vlan** | **remote**]] [**ip-address** *ipv6-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display local IPv6SG bindings that can be synchronized by routing protocols.	**display ipv6 source binding-local** [**interface** *interface-type interface-number*] [**dhcpv6-relay** | **nd-snooping-vlan**] [**ip-address** *ipv6-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]
Display remote IPv6SG bindings synchronized by routing protocols.	**display ipv6 source binding-remote** [**router-id** *router-id*] [**dhcpv6-relay** | **nd-snooping-vlan**] [**ip-address** *ipv6-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]
Display IPv6SG prefix bindings.	**display ipv6 source binding pd** [**vpn-instance** *vpn-instance-name*] [**prefix** *prefix/prefix-length*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display statistics about local and remote IPv6SG bindings that routing protocols synchronize.	**display ipv6 source binding statistics**

IPSG configuration examples

Example: Configuring static IPv4SG

Network configuration

As shown in Figure 2, all hosts use static IP addresses.

Configure static IPv4SG bindings on Device A and Device B to meet the following requirements:

- All interfaces of Device A allow IP packets from Host A to pass.
- GigabitEthernet 1/0/1 of Device A allows IP packets from Host B to pass.

Figure 2 Network diagram

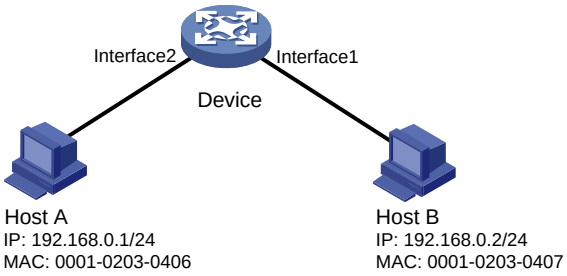


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

Configure IP addresses for the interfaces. (Details not shown.)

Enable IPv4SG on GigabitEthernet 1/0/2.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] ip verify source ip-address mac-address
[DeviceA-GigabitEthernet1/0/2] quit
```

Configure a static IPv4SG binding for Host A.

```
[DeviceA] ip source binding ip-address 192.168.0.1 mac-address 0001-0203-0406
```

Enable IPv4SG on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip verify source ip-address mac-address
```

On GigabitEthernet 1/0/1, configure a static IPv4SG binding for Host B.

```
[DeviceA-GigabitEthernet1/0/1] ip source binding mac-address 0001-0203-0407
[DeviceA-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify that the static IPv4SG bindings are configured successfully on Device A.

```
<DeviceA> display ip source binding static
Total entries found: 2
IP address      MAC address    Interface              VLAN Type
192.168.0.1     0001-0203-0406 N/A                    N/A  Static
N/A             0001-0203-0407 GE1/0/1                N/A  Static
```

Example: Configuring DHCP snooping-based dynamic IPv4SG

Network configuration

As shown in Figure 3, the host (the DHCP client) obtains an IP address from the DHCP server. Perform the following tasks:

- Enable DHCP snooping on the device to make sure the DHCP client obtains an IP address from the authorized DHCP server. To generate a DHCP snooping entry for the DHCP client, enable recording of client information in DHCP snooping entries.
- Enable dynamic IPv4SG on GigabitEthernet 1/0/1 to filter incoming packets by using the IPv4SG bindings generated based on DHCP snooping entries. Only packets from the DHCP client are allowed to pass.

Figure 3 Network diagram

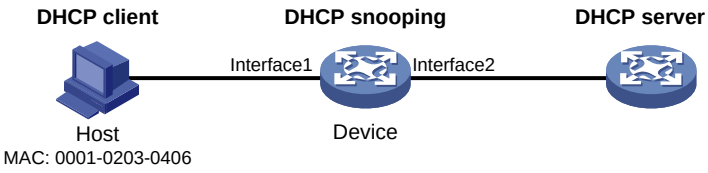

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure the DHCP server.

   For information about DHCP server configuration, see *Layer 3—IP Services Configuration Guide*.

2. Configure the device:

   # Configure IP addresses for the interfaces. (Details not shown.)

   # Enable DHCP snooping.

   ```
   <Device> system-view
   [Device] dhcp snooping enable
   ```

   # Configure GigabitEthernet 1/0/2 as a trusted interface.

   ```
   [Device] interface gigabitethernet 1/0/2
   [Device-GigabitEthernet1/0/2] dhcp snooping trust
   [Device-GigabitEthernet1/0/2] quit
   ```

   # Enable IPv4SG on GigabitEthernet 1/0/1 and verify the source IP address and MAC address for dynamic IPSG.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip verify source ip-address mac-address
   ```

   # Enable recording of client information in DHCP snooping entries on GigabitEthernet 1/0/1.

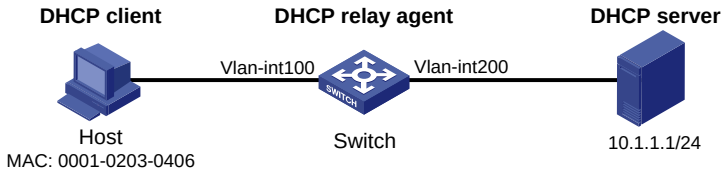
   ```
   [Device-GigabitEthernet1/0/1] dhcp snooping binding record
   [Device-GigabitEthernet1/0/1] quit
   ```

Verifying the configuration

Display dynamic IPv4SG bindings generated based on DHCP snooping entries.

```
[Device] display ip source binding dhcp-snooping
Total entries found: 1
IP address      MAC address    Interface               VLAN Type
192.168.0.1     0001-0203-0406 GE1/0/1                 1    DHCP snooping
```

GigabitEthernet 1/0/1 will filter packets based on the IPv4SG binding.



Example: Configuring DHCP relay agent-based dynamic IPv4SG

Network configuration

As shown in Figure 4, DHCP relay agent is enabled on the switch. The host obtains an IP address from the DHCP server through the DHCP relay agent.

Enable dynamic IPv4SG on VLAN-interface 100 to filter incoming packets by using the IPv4SG bindings generated based on DHCP relay entries.

Figure 4 Network diagram

Procedure

1. Configure dynamic IPv4SG:

   # Configure IP addresses for the interfaces. (Details not shown.)

   # Enable IPv4SG on VLAN-interface 100 and verify the source IP address and MAC address for dynamic IPSG.

   ```
   <Switch> system-view
   [Switch] interface vlan-interface 100
   [Switch-Vlan-interface100] ip verify source ip-address mac-address
   [Switch-Vlan-interface100] quit
   ```

2. Configure the DHCP relay agent:

   # Enable the DHCP service.

   ```
   [Switch] dhcp enable
   ```

   # Enable recording DHCP relay entries.

   ```
   [Switch] dhcp relay client-information record
   ```

   # Configure VLAN-interface 100 to operate in DHCP relay mode.

   ```
   [Switch] interface vlan-interface 100
   [Switch-Vlan-interface100] dhcp select relay
   ```

   # Specify the IP address of the DHCP server.

   ```
   [Switch-Vlan-interface100] dhcp relay server-address 10.1.1.1
   [Switch-Vlan-interface100] quit
   ```

Verifying the configuration

Display dynamic IPv4SG bindings generated based on DHCP relay entries.

```
[Switch] display ip source binding dhcp-relay
Total entries found: 1
IP address      MAC address    Interface               VLAN Type
192.168.0.1     0001-0203-0406 Vlan100                 100  DHCP relay
```

VLAN-interface 100 will filter packets based on the IPv4SG binding.

Example: Configuring static IPv6SG

Network configuration

As shown in Figure 5, configure a static IPv6SG binding on GigabitEthernet 1/0/1 of the device to allow only IPv6 packets from the host to pass.

Figure 5 Network diagram

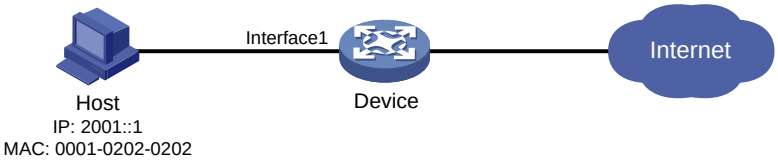


Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Enable IPv6SG on GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ipv6 verify source ip-address mac-address
```

On GigabitEthernet 1/0/1, configure a static IPv6SG binding for the host.

```
[Device-GigabitEthernet1/0/1] ipv6 source binding ip-address 2001::1 mac-address
0001-0202-0202
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify that the static IPv6SG binding is configured successfully on the device.

```
[Device] display ipv6 source binding static
Total entries found: 1
IPv6 address         MAC address    Interface             VLAN Type
2001::1              0001-0202-0202 GE1/0/1               N/A  Static
```

Example: Configuring DHCPv6 snooping-based dynamic IPv6SG address bindings

Network configuration

As shown in Figure 6, the host (the DHCPv6 client) obtains an IP address from the DHCPv6 server. Perform the following tasks:

- Enable DHCPv6 snooping on the device to make sure the DHCPv6 client obtains an IPv6 address from the authorized DHCPv6 server. To generate a DHCPv6 snooping entry for the DHCPv6 client, enable recording of client information in DHCPv6 snooping entries.
- Enable dynamic IPv6SG on GigabitEthernet 1/0/1 to filter incoming packets by using the IPv6SG bindings generated based on DHCPv6 snooping entries. Only packets from the DHCPv6 client are allowed to pass.

Figure 6 Network diagram

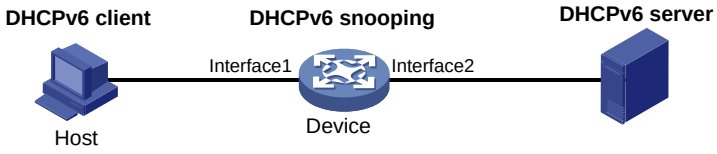

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure DHCPv6 snooping:

   # Enable DHCPv6 snooping globally.

   ```
   <Device> system-view
   [Device] ipv6 dhcp snooping enable
   ```

   # Configure GigabitEthernet 1/0/2 as a trusted interface.

   ```
   [Device] interface gigabitethernet 1/0/2
   [Device-GigabitEthernet1/0/2] ipv6 dhcp snooping trust
   [Device-GigabitEthernet1/0/2] quit
   ```

2. Enable IPv6SG:

   # Enable IPv6SG on GigabitEthernet 1/0/1 and verify the source IP address and MAC address for dynamic IPv6SG.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ipv6 verify source ip-address mac-address
   ```

   # Enable recording of client information in DHCPv6 snooping entries on GigabitEthernet 1/0/1.

   ```
   [Device-GigabitEthernet1/0/1] ipv6 dhcp snooping binding record
   [Device-GigabitEthernet1/0/1] quit
   ```

Verifying the configuration

Display dynamic IPv6SG bindings generated based on DHCPv6 snooping entries.

```
[Device] display ipv6 source binding dhcpv6-snooping
Total entries found: 1
IPv6 address         MAC address    Interface             VLAN Type
2001::1              040a-0000-0001 GE1/0/1               1    DHCPv6 snooping
```

GigabitEthernet 1/0/1 will filter packets based on the IPv6SG binding.

Example: Configuring DHCPv6 snooping-based dynamic IPv6SG prefix bindings

Network configuration

As shown in Figure 7, the host (the DHCPv6 client) obtains an IPv6 prefix from the DHCPv6 server. Perform the following tasks:

- Enable DHCPv6 snooping on the device to make sure the DHCPv6 client obtains an IPv6 prefix from the authorized DHCPv6 server. To generate a DHCPv6 snooping prefix entry for the DHCPv6 client, enable recording IPv6 prefix information in DHCPv6 snooping entries.

- Enable dynamic IPv6SG on GigabitEthernet 1/0/1 to filter incoming packets by using the IPv6SG bindings generated based on DHCPv6 snooping prefix entries. Only packets from the DHCPv6 client are allowed to pass.

Figure 7 Network diagram

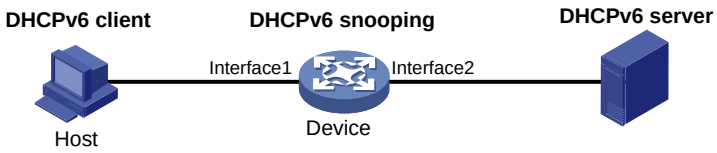

Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure DHCPv6 snooping.

   # Enable DHCPv6 snooping globally.

   ```
   <Device> system-view
   [Device] ipv6 dhcp snooping enable
   ```

   # Configure GigabitEthernet 1/0/2 as a trusted interface.

   ```
   [Device] interface gigabitethernet 1/0/2
   [Device-GigabitEthernet1/0/2] ipv6 dhcp snooping trust
   [Device-GigabitEthernet1/0/2] quit
   ```

   # Enable recording DHCPv6 snooping prefix entries on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ipv6 dhcp snooping pd binding record
   ```

2. Enable IPv6SG.

   # Enable IPv6SG on GigabitEthernet 1/0/1 and verify the source IP address and MAC address for dynamic IPv6SG.

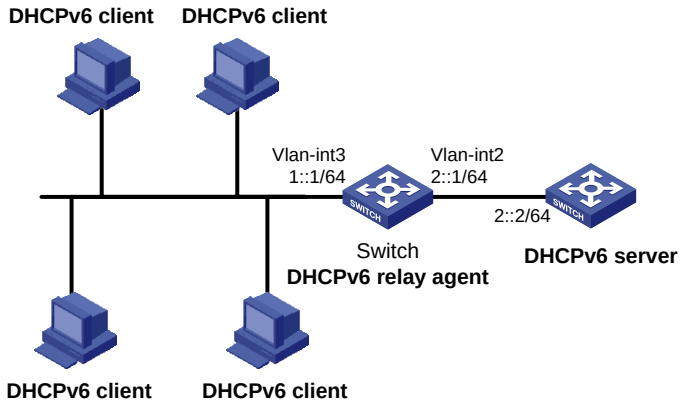
   ```
   [Device-GigabitEthernet1/0/1] ipv6 verify source ip-address mac-address
   [Device-GigabitEthernet1/0/1] quit
   ```

Verifying the configuration

Display dynamic IPv6SG bindings generated based on DHCPv6 snooping entries.

```
[Device] display ipv6 source binding pd
Total entries found: 1
IPv6 address         MAC address    Interface              VLAN Type
2001:410:1::/48      0010-9400-0004 GE1/0/1                1
```

GigabitEthernet 1/0/1 will filter packets based on the IPv6SG binding.



Example: Configuring DHCPv6 relay agent-based dynamic IPv6SG

Network configuration

As shown in Figure 8, DHCPv6 relay agent is enabled on the switch. The clients obtain IPv6 addresses from the DHCPv6 server through the DHCPv6 relay agent.

Enable dynamic IPv6SG on VLAN-interface 3 to filter incoming packets by using the IPv6SG bindings generated based on DHCPv6 relay entries.

Figure 8 Network diagram

Procedure

1. Configure the DHCPv6 relay agent:

   # Create VLAN 2 and VLAN 3, assign interfaces to the VLANs, and specify IP addresses for VLAN-interface 2 and VLAN-interface 3. (Details not shown.)

   # Enable the DHCPv6 relay agent on VLAN-interface 3.

   ```
   <Switch> system-view
   [Switch] interface vlan-interface 3
   [Switch-Vlan-interface3] ipv6 dhcp select relay
   ```

   # Enable recording of DHCPv6 relay entries on the interface.

   ```
   [Switch-Vlan-interface3] ipv6 dhcp relay client-information record
   ```

   # Specify the DHCPv6 server address 2::2 on the relay agent.

   ```
   [Switch-Vlan-interface3] ipv6 dhcp relay server-address 2::2
   ```

2. Enable IPv6SG on VLAN-interface 3 and verify the source IP address and MAC address for dynamic IPv6SG.

   ```
   [Switch-Vlan-interface3] ipv6 verify source ip-address mac-address
   [Switch-Vlan-interface3] quit
   ```

Verifying the configuration

Display dynamic IPv6SG bindings generated based on DHCPv6 relay entries.

```
[Switch] display ipv6 source binding dhcpv6-relay
Total entries found: 1
IP Address      MAC Address    Interface               VLAN Type
1::2            0001-0203-0406 Vlan3                   3    DHCPv6 relay
```

VLAN-interface 3 will filter packets based on the IPv6SG binding.

Configuring ARP attack protection

About ARP attack protection

The device can provide multiple features to detect and prevent ARP attacks and viruses in the LAN. An attacker can exploit ARP vulnerabilities to attack network devices in the following ways:

- Sends a large number of unresolvable IP packets to have the receiving device busy with resolving IP addresses until its CPU is overloaded. Unresolvable IP packets refer to IP packets for which ARP cannot find corresponding MAC addresses.
- Sends a large number of ARP packets to overload the CPU of the receiving device.
- Acts as a trusted user or gateway to send ARP packets so the receiving devices obtain incorrect ARP entries.

ARP attack protection tasks at a glance

All ARP attack protection tasks are optional.

- Preventing flood attacks
  - Configuring unresolvable IP attack protection
  - Configuring source MAC-based ARP packet rate limiting
  - Configuring source MAC-based ARP attack detection
- Preventing user and gateway spoofing attacks
  - Configuring ARP packet source MAC consistency check
  - Configuring ARP active acknowledgement
  - Configuring authorized ARP
  - Configuring ARP attack detection
  - Configuring ARP scanning and fixed ARP
  - Configuring ARP keepalive entry scanning
  - Configuring ARP gateway protection
  - Configuring ARP filtering
  - Configuring ARP sender IP address checking
  - Configuring ARP entry fixing
- Enabling SNMP notifications for ARP

Configuring unresolvable IP attack protection

About unresolvable IP attack protection

If a device receives a large number of unresolvable IP packets from a host, the following situations can occur:

- The device sends a large number of ARP requests, overloading the target subnets.
- The device keeps trying to resolve the destination IP addresses, overloading its CPU.

To protect the device from such IP attacks, you can configure the following features:

- **ARP source suppression**—This feature is applicable if the attack packets have the same source addresses.
- **ARP blackhole routing**—This feature is applicable regardless of whether the attack packets have the same source addresses.

Configuring ARP source suppression

About this task

This feature stops resolving packets from an IP address if the number of unresolvable IP packets from the IP address exceeds the upper limit within 5 seconds. The device continues ARP resolution when the interval elapses.

For a gateway or server trusted by the device, you can configure an ARP source suppression rule so that the device always permits IP packets sourced from the IP address of the gateway or server.

Restrictions and guidelines

To have the configured ARP source suppression rules take effect, you must enable ARP source suppression by using the **arp source-suppression enable** command.

Procedure

1. Enter system view.

   system-view
2. Enable ARP source suppression.

   arp source-suppression enable

   By default, ARP source suppression is disabled.
3. Set the maximum number of unresolvable packets that the device can process per source IP address within 5 seconds.

   arp source-suppression limit *limit-value*

   By default, the maximum number is 10.
4. Configure ARP source suppression rules.

   arp source-suppression rule *rule-id* **permit** *ip-address* [*mask*]

   By default, no ARP source suppression rules exist.

Configuring ARP blackhole routing

About this task

This feature creates a blackhole route destined for an unresolved IP address. The device drops all matching packets until the blackhole route is deleted. A blackhole route is deleted when its aging timer is reached or the route becomes reachable.

After a blackhole route is created for an unresolved IP address, the device immediately starts the first ARP blackhole route probe by sending an ARP request. If the resolution fails, the device continues probing according to the probe settings. If the IP address resolution succeeds in a probe, the device converts the blackhole route to a normal route. If an ARP blackhole route ages out before the device finishes all probes, the device deletes the blackhole route and does not perform the remaining probes.

Restrictions and guidelines

Set the ARP blackhole route probe count to a big value, for example, 25. If the device fails to reach the destination IP address temporarily and the probe count is too small, all probes might finish before the problem is resolved. As a result, non-attack packets will be dropped. This setting can avoid such situation.

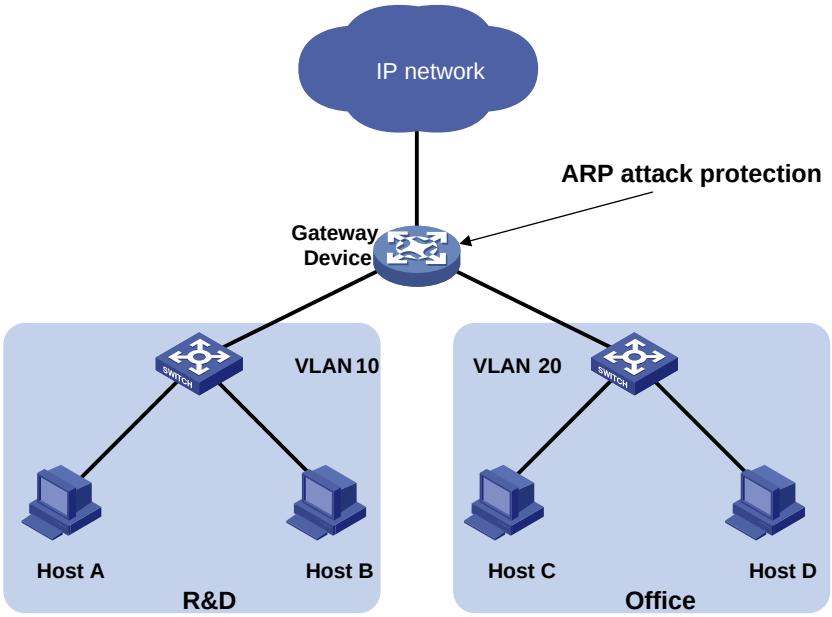
Procedure

1. Enter system view.
   system-view
2. Enable ARP blackhole routing.
   arp resolving-route enable
   By default, ARP blackhole routing is enabled.
3. (Optional.) Set the number of ARP blackhole route probes for each unresolved IP address.
   arp resolving-route probe-count *count*
   The default setting is three probes.
4. (Optional.) Set the interval at which the device probes ARP blackhole routes.
   arp resolving-route probe-interval *interval*
   The default setting is 1 second.

Display and maintenance commands for unresolvable IP attack protection

Execute **display** commands in any view.

Task	Command
Display ARP source suppression configuration information.	**display arp source-suppression**
Display ARP source suppression entries.	**display arp source-suppression cache** [**slot** *slot-number*]



Example: Configuring unresolvable IP attack protection

Network configuration

As shown in Figure 1, a LAN contains two areas: an R&D area in VLAN 10 and an office area in VLAN 20. Each area connects to the gateway (Device) through an access switch.

A large number of ARP requests are detected in the office area and are considered an attack caused by unresolvable IP packets. To prevent the attack, configure ARP source suppression or ARP blackhole routing.

Figure 1 Network diagram

Procedure

- If the attack packets have the same source address, configure ARP source suppression:

  # Enable ARP source suppression.

  ```
  <Device> system-view
  [Device] arp source-suppression enable
  ```

  # Configure the device to process a maximum of 100 unresolvable packets per source IP address within 5 seconds.

  ```
  [Device] arp source-suppression limit 100
  ```

- If the attack packets have different source addresses, configure ARP blackhole routing:

  # Enable ARP blackhole routing.

  ```
  [Device] arp resolving-route enable
  ```

Configuring source MAC-based ARP packet rate limiting

About this task

A client might send a large number of ARP requests, which might cause high CPU usage on the gateway, adversely affect other services, and even crash the device. To resolve the issue, use the source MAC-based ARP packet rate limit to limit the receiving rate of ARP packets from the client. When the receiving rate of ARP requests from the client exceeds the limit, the device will discard subsequent ARP requests.

You can use the **`debugging arp packet`** command to view the source MAC addresses from which the rate of ARP packets is high.

Restrictions and guidelines

You can configure both global rate limit for all ARP packets and MAC-specific rate limit for ARP packets from specific MAC addresses. For the ARP packets from a specific MAC address, the global limit rate or MAC-specific limit rate whichever is smaller applies. If you execute the **`undo arp`**

rate-limit source-mac command without specifying the *mac-address* argument, the command disables only global rate limit. MAC-specific rate limit for ARP packets still takes effect.

If you set both ARP packet rate limits on interfaces and source MAC-based ARP packet rate limit, the rate limit works as follows:

- For the system, the rate limit that takes effect is the one with a smaller value between the sum of rate limits that take effect on the interfaces receiving ARP packets from the MAC address and the source MAC-based ARP packet rate limit.
- For an interface, the rate limit that takes effect is the one with a smaller value between the ARP packet rate limit and the actual ARP packet traffic received by the interface.

Procedure

1. Enter system view.
   system-view
2. Enable source MAC-based ARP packet rate limiting and set the limit rate.
   arp rate-limit source-mac [*mac-address*] *pps*
   By default, source MAC-based ARP packet rate limiting is disabled.

Configuring source MAC-based ARP attack detection

About this task

This feature checks the number of ARP packets delivered to the CPU. If the number of packets from the same MAC address within 5 seconds exceeds a threshold, the device generates an ARP attack detection entry for the MAC address. If logging is enabled for source MAC-based ARP attack detection, the device handles the attack by using either of the following methods before the ARP attack detection entry ages out:

- **Monitor**—Only generates log messages.
- **Filter**—Generates log messages and filters out subsequent ARP packets from the MAC address and data packets sourced from or destined for the MAC address.

When an ARP attack detection entry ages out, ARP packets sourced from the MAC address in the entry can be processed correctly.

Some security devices or servers might send a large number of ARP packets for security check. To prevent such ARP packets from being filtered out, exclude the MAC addresses of these devices from source MAC-based ARP attack detection. The device will directly permit the packets sourced from the MAC addresses.

Restrictions and guidelines

When you change the handling method from monitor to filter, the configuration takes effect immediately. When you change the handling method from filter to monitor, the device continues filtering packets that match existing ARP attack detection entries, and uses the monitor method to process packets that match the new ARP attack detection entries.

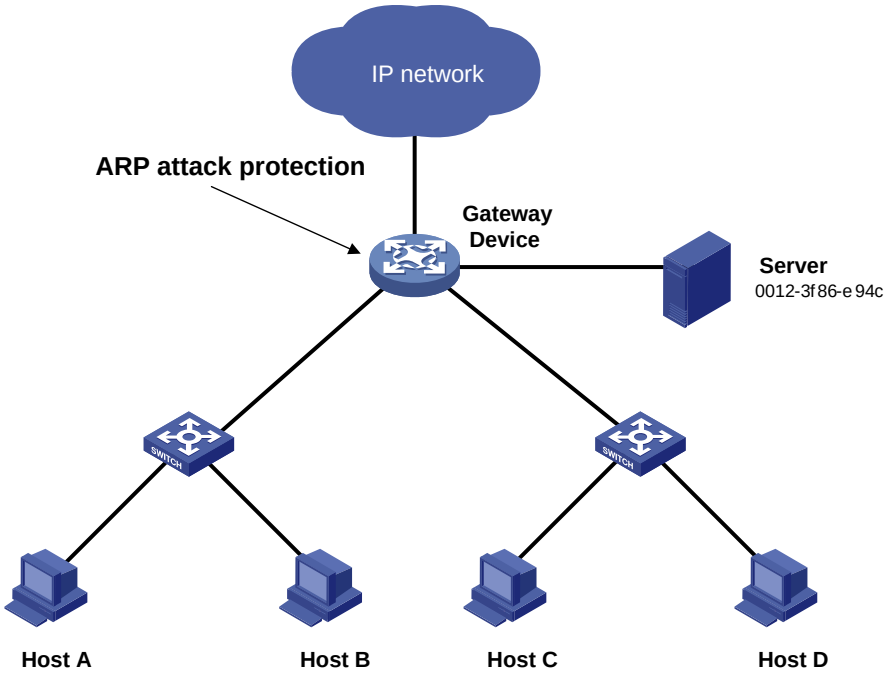
Procedure

1. Enter system view.
   system-view

2. Enable source MAC-based ARP attack detection and specify the handling method.
   arp source-mac { **filter** | **monitor** }
   By default, this feature is disabled.
3. Set the threshold.
   arp source-mac threshold *threshold-value*
   By default, the threshold is 30.
4. Set the aging timer for ARP attack detection entries.
   arp source-mac aging-time *time*
   By default, the lifetime is 300 seconds.
5. (Optional.) Exclude specific MAC addresses from this detection.
   arp source-mac exclude-mac *mac-address*&<1-10>
   By default, no MAC address is excluded.
6. Enable logging for source MAC-based ARP attack detection.
   arp source-mac log enable
   By default, logging for source MAC-based ARP attack detection is disabled.

Display and maintenance commands for source MAC-based ARP attack detection

Execute **display** commands in any view.



Task	Command
Display ARP attack detection entries generated by source MAC-based ARP attack detection.	**display arp source-mac** { **interface** *interface-type interface-number* [**slot** *slot-number*] | **slot** *slot-number* }

Example: Configuring source MAC-based ARP attack detection

Network configuration

As shown in Figure 2, the hosts access the Internet through a gateway (Device). If malicious users send a large number of ARP requests to the gateway, the gateway might crash and cannot process requests from the clients. To solve this problem, configure source MAC-based ARP attack detection on the gateway.

Figure 2 Network diagram

Procedure

Enable source MAC-based ARP attack detection, and specify the handling method as filter.

```
<Device> system-view
[Device] arp source-mac filter
```

Set the threshold to 30.

```
[Device] arp source-mac threshold 30
```

Set the lifetime for source MAC-based ARP attack detection entries to 60 seconds.

```
[Device] arp source-mac aging-time 60
```

Exclude MAC address 0012-3f86-e94c from this detection.

```
[Device] arp source-mac exclude-mac 0012-3f86-e94c
```

Configuring ARP packet source MAC consistency check

About ARP packet source MAC consistency check

This feature enables a gateway to filter ARP packets whose source MAC address in the Ethernet header is different from the sender MAC address in the message body. This feature allows the gateway to learn correct ARP entries.

Procedure

1. Enter system view.
   `system-view`
2. Enable ARP packet source MAC address consistency check.

arp valid-check enable

By default, ARP packet source MAC address consistency check is disabled.

Configuring ARP active acknowledgement

About this task

Use the ARP active acknowledgement feature on gateways to prevent user spoofing.

This feature enables the device to perform active acknowledgement before creating an ARP entry.

- Upon receiving an ARP request that requests the MAC address of the device, the device sends an ARP reply. Then, it sends an ARP request for the sender IP address in the received ARP request to determine whether to create an ARP entry for the sender IP address.
  - If the device receives an ARP reply within the probe interval, it creates the ARP entry.
  - If the device does not receive an ARP reply within the probe interval, it does not create the ARP entry.
- Upon receiving an ARP reply, the device examines whether it was the reply to the request that the device has sent.
  - If it was, the device creates an ARP entry for the sender IP address in the ARP reply.
  - If it was not, the device sends an ARP request for the sender IP address to determine whether to create an ARP entry for the sender IP address.
    - If the device receives an ARP reply within the probe interval, it creates the ARP entry.
    - If the device does not receive an ARP reply within the probe interval, it does not create the ARP entry.

To improve validity and reliability of ARP entries, you can enable ARP active acknowledgement in strict mode. In this mode, the device creates ARP entries only for the IP addresses that the device actively initiates the ARP resolution.

Procedure

1. Enter system view.

   system-view
2. Enable ARP active acknowledgement.

   arp active-ack [**strict**] **enable**

   By default, ARP active acknowledgement is disabled.

   For ARP active acknowledgement to take effect in strict mode, make sure ARP blackhole routing is enabled.

Configuring authorized ARP

About authorized ARP

Authorized ARP entries are generated based on the DHCP clients' address leases on the DHCP server or dynamic client entries on the DHCP relay agent. For more information about DHCP server and DHCP relay agent, see *Layer 3—IP Services Configuration Guide*.

Use this feature to prevent user spoofing and to allow only authorized clients to access network resources.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

   Supported interface types include Layer 3 Ethernet interface, Layer 3 Ethernet subinterface, Layer 3 aggregate interface, Layer 3 aggregate subinterface, and VLAN interface.

3. Enable authorized ARP on the interface.

   arp authorized enable

   By default, authorized ARP is disabled.

Example: Configuring authorized ARP on a DHCP server

Network configuration

As shown in Figure 3, configure authorized ARP on Vlan-interface2 of Switch A (a DHCP server) to ensure user validity.

Figure 3 Network diagram

Procedure

1. Configure Switch A:

   # Specify the IP address for Vlan-interface2.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 10.1.1.1 24
   [SwitchA-Vlan-interface2] quit
   ```

   # Configure DHCP.

   ```
   [SwitchA] dhcp enable
   [SwitchA] dhcp server ip-pool 1
   [SwitchA-dhcp-pool-1] network 10.1.1.0 mask 255.255.255.0
   [SwitchA-dhcp-pool-1] quit
   ```

   # Enter VLAN interface view.

   ```
   [SwitchA] interface vlan-interface 2
   ```

   # Enable authorized ARP.

   ```
   [SwitchA-Vlan-interface2] arp authorized enable
   [SwitchA-Vlan-interface2] quit
   ```

2. Configure Switch B:

   ```
   <SwitchB> system-view
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] ip address dhcp-alloc
   [SwitchB-Vlan-interface2] quit
   ```

Verifying the configuration

Display authorized ARP entry information on Switch A.

```
[SwitchA] display arp all
  Type: S-Static   D-Dynamic   O-Openflow   R-Rule   M-Multiport  I-Invalid
IP address      MAC address    VLAN/VSI name Interface               Aging Type
10.1.1.2        0012-3f86-e94c 2             GE1/0/1                 960   D
```

The output shows that IP address 10.1.1.2 has been assigned to Switch B.

Switch B must use the IP address and MAC address in the authorized ARP entry to communicate with Switch A. Otherwise, the communication fails. Thus user validity is ensured.

Example: Configuring authorized ARP on a DHCP relay agent

Network configuration

As shown in Figure 4, configure authorized ARP on GigabitEthernet 1/0/2 of Device B (a DHCP relay agent) to ensure user validity.

Figure 4 Network diagram

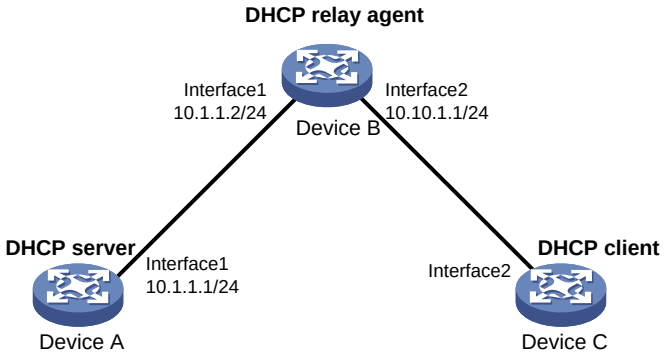


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure Device A:

   # Specify the IP address for GigabitEthernet 1/0/1.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 10.1.1.1 24
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure DHCP.

   ```
   [DeviceA] dhcp enable
   [DeviceA] dhcp server ip-pool 1
   [DeviceA-dhcp-pool-1] network 10.10.1.0 mask 255.255.255.0
   [DeviceA-dhcp-pool-1] gateway-list 10.10.1.1
   ```

```
[DeviceA-dhcp-pool-1] quit
[DeviceA] ip route-static 10.10.1.0 24 10.1.1.2
```

2. Configure Device B:

   # Enable DHCP.

```
<DeviceB> system-view
[DeviceB] dhcp enable
```

   # Specify the IP addresses of GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 10.1.1.2 24
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] ip address 10.10.1.1 24
```

   # Enable DHCP relay agent on GigabitEthernet 1/0/2.

```
[DeviceB-GigabitEthernet1/0/2] dhcp select relay
```

   # Add the DHCP server 10.1.1.1 to DHCP server group 1.

```
[DeviceB-GigabitEthernet1/0/2] dhcp relay server-address 10.1.1.1
```

   # Enable authorized ARP.

```
[DeviceB-GigabitEthernet1/0/2] arp authorized enable
[DeviceB-GigabitEthernet1/0/2] quit
```

   # Enable recording of relay entries on the relay agent.

```
[DeviceB] dhcp relay client-information record
```

3. Configure Device C:

```
